Arm® Arm926EJ-S™ Processor-Based MPU, 800 MHz, MIPI DSI® or CSI-2, LVDS, RGB, 2D Graphics, Gigabit Ethernet with TSN, CAN-FD, Octal/Quad SPI, Crypto, PUF

SAM9X7 Series Data Sheet

Product Page Links

Introduction

The SAM9X7 Series microprocessors are high-performance and cost-optimized Arm926EJ-S CPU-based embedded microprocessors (MPU), running up to 800 MHz. The devices integrate powerful peripherals for connectivity and user interface applications, including MIPI DSI, LVDS, RGB and 2D graphics, MIPI-CSI-2, Gigabit Ethernet with TSN and CAN-FD. Advanced security functions are offered, such as tamper detection, secure boot, secure key storage, TRNG, PUF as well as high-performance crypto accelerators for AES and SHA. The SAM9X7 Series is supported by Microchip MPLAB®-X development tools, Harmony, Linux® distributions and the Ensemble Graphics Toolkit.

The SAM9X7 Series is available in ambient temperature ranges up to 105°C and is AEC-Q100 grade 2 qualified.

Reference Document

The SAM9X7 Series device conforms functionally to this data sheet, except for the anomalies described in the following document.

Type	Title	Literature No.	Available

Overview

1. Features

- CPU Running up to 800 MHz
  - Arm926EJ-S Arm Thumb® processor
  - 32-Kbyte data cache, 32-Kbyte instruction cache, Memory Management Unit (MMU)
- Memories
  - One 176-Kbyte internal ROM
    - 80-Kbyte internal ROM embedding a secure bootloader program supporting boot on NAND Flash, SD card, SPI or QSPI Flash; bootloader features selectable by OTP bits
    - 96-Kbyte ROM for NAND Flash BCH ECC table
  - One 64-Kbyte internal SRAM (SRAM0), single cycle access at system speed
  - DDR3(L)/DDR2 controller running at up to 266 MHz
  - External Bus Interface (EBI) supporting:
    - 16-bit 8/4-bank DDR3(L)/DDR2
    - 16-bit static memories
    - 8-bit NAND Flash with up to 24-bit programmable multi-bit error correcting code
  - One 10-Kbyte OTP memory for secure key storage with Emulation mode (OTP bits are emulated by a 4-Kbyte SRAM (SRAM1))
- System Running up to 266 MHz
  - Power-on reset cells, reset controller, shutdown controller, periodic interval timer, watchdog timer running on internal slow RC oscillator (32 kHz typical) and real-time clock running on slow crystal oscillator (32.768 kHz)
  - Two internal trimmed RC oscillators with typical values: 32 kHz (slow) and 12 MHz (fast)
  - Two crystal oscillators: 32.768 kHz (slow) and 20 to 50 MHz (fast)
  - One PLL for the system and one PLL optimized for USB high-speed operation (480 MHz)
    - One PLL for audio operations, with dedicated output clock
    - One PLL in LVDS I/F (LVDS usage only)
    - One PLL in MIPI D-PHY (MIPI DSI usage only)
  - One dual-port 16-channel DMA controller
  - Advanced interrupt controller and debug unit
  - JTAG port with disable bit in OTP memory
  - Two programmable clock output signals
- Low-Power Modes
  - Backup mode with RTC, eight 32-bit general purpose backup registers, and shutdown controller to control the external power supply
  - Clock generator and power management controller
  - Software-programmable ultra-low power modes: Very slow clock operating mode (ULP0), and no-clock operating mode (ULP1) with fast wake-up capabilities
  - Software programmable power optimization capabilities
- Peripherals

© 2026 Microchip Technology Inc. and its subsidiaries

  - LCD controller with overlay, alpha-blending, rotation, scaling and color conversion; display size up to 1024x768 (XGA) with overlay (application-dependent); still images up to 1280x720 (720p)
  - RGB, LVDS, MIPI DSI interfaces (see Configuration Summary)
  - 2D graphics controller supporting fill BLT, copy BLT, transparent BLT, blend/alpha BLT, ROP4 BLT (raster operations) and command ring buffer
  - Image sensor controller with ITU-R BT; 601/656/1120 video interface support up to 5 Mpixels; support of raw Bayer 12, YCbCr, monochrome and JPEG compressed sensors up to 12 bits
    - MIPI CSI2 I/F support
    - 12-bit parallel I/F support
  - One high-speed USB device, three high-speed USB hosts with dedicated on-chip transceivers
  - One 10/100/1000 Mbps Ethernet Mac controller, with IEEE® -1588 and TSN support, RGMII and RMII support
  - Two 4-bit secure digital multimedia card controllers
  - Two CAN FD controllers with timestamping
  - One Quad/Octal SPI controller
  - Two 3-channel 32-bit timers/counters
  - Two high-resolution (64-bit) periodic interval timers
  - One synchronous serial controller
  - One inter-IC sound multi-channel controller with TDM support
  - One audio class D controller with single-ended or bridge-tied load connection to power stage
  - One 4-channel 16-bit PWM controller
  - Thirteen FLEXCOMs (USART, SPI and TWI/I2C)
  - One 8-channel, 12-bit, analog-to-digital converter with 4/5 wires resistive touchscreen support
- Hardware Cryptography
  - SHA (SHA1, SHA224, SHA256, SHA384, SHA512) and HMAC compliant with FIPS PUB 180
  - AES: 256-, 192-, 128-bit key algorithms compliant with FIPS PUB 197
  - AES/SHA tight coupling for IPsec hardware acceleration
  - TDES: 2-key or 3-key algorithms compliant with FIPS PUB 46
  - True random number generator compliant with NIST Special Publication 800-22 Test Suite and FIPS PUBs 140-2 and 140-3
  - Key bus providing private key transfers between AES, TDES, TRNG, OTPC
  - Physical Unclonable Function (PUF) including NIST SP 800-90B (DRNG) and embedding four Kbytes of SRAM (PUFSRAM)
- I/O Ports
  - Four parallel input/output controllers
  - Up to 106 programmable I/O lines multiplexed with up to four peripheral I/Os
  - Input change interrupt capability on each I/O line, optional Schmitt trigger input
  - Individually programmable open-drain, pull-up and pull-down resistors, synchronous output
  - General-purpose analog and digital inputs tolerant to positive and negative current injection
- Design for low ElectroMagnetic Interference (EMI)
  - Slewrate-controlled I/Os

© 2026 Microchip Technology Inc. and its subsidiaries

  - DDR PHY with impedance-calibrated drivers
  - Spread spectrum PLLs
  - BGA power/ground ball assignment to provide optimum decoupling capacitors placement
- Operating Conditions
  - Junction temperature (T_J) range: -40°C to +125°C
  - SAM9X7x-I devices ambient temperature (T_A) range: -40°C to +85°C
  - SAM9X7x-V devices ambient temperature (T_A) range: -40°C to +105°C
- Qualification
  - AEC-Q100 Grade 2 ([-40°C to +105°C] ambient temperature) applies to -V/4PBVAO devices only
  - The AEC-Q006 set of tests applies, as only copper wire interconnections are used
- Packages
  - 11x11 mm^2, 0.65-mm pitch, 240-ball BGA optimized for standard class PCB layout (down to four layers)
  - 9x9 mm^2, 0.5-mm pitch, 256-ball BGA for space-constrained applications

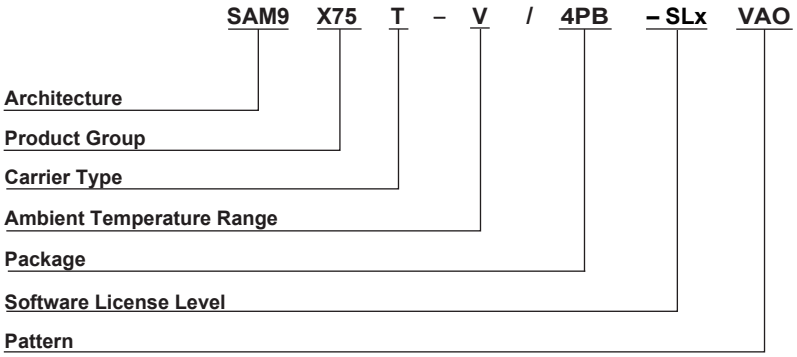
2. Ordering Information

Ordering Code[1][2]	Tier	Package	Ambient Operating Temperature Range
SAM9X70(T)-I/4PB(-SLx)	Industrial	TFBGA240	-40°C to +85°C
SAM9X72(T)-I/4PB(-SLx)			
SAM9X75(T)-I/4PB(-SLx)			
SAM9X70(T)-V/4PB(-SLx)	Extended Industrial	TFBGA240	-40°C to +105°C
SAM9X72(T)-V/4PB(-SLx)			
SAM9X75(T)-V/4PB(-SLx)			
SAM9X70(T)-V/6GW(-SLx)	Extended Industrial	TFBGA256	-40°C to +105°C
SAM9X72(T)-V/6GW(-SLx)			
SAM9X75(T)-V/6GW(-SLx)			
SAM9X75(T)-V/4PB(-SLx)VAO	Automotive	TFBGA240	-40°C to +105°C



Notes:

1. For details on ordering codes, refer to Product Identification System.
2. For SL1, SL2 and SL3 device availability, contact a Microchip Sales representative.

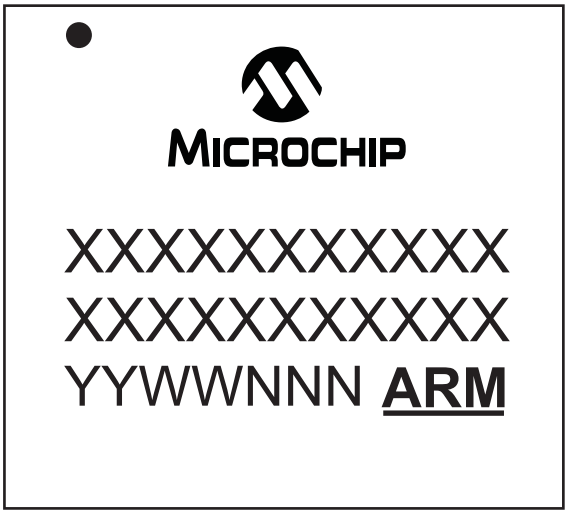
3. Product Identification System

To order or obtain information, e.g., on pricing or delivery, refer to the factory or the listed sales office.



Architecture:	SAM9	= Arm926EJ-S Arm Thumb microprocessor
Product Group:	X70	= General purpose microprocessors with variable feature set
	X72	
	X75	
Carrier Type:	Blank	= Standard packaging (tray)
	T	= Tape and reel
Ambient Temperature Range:	I	= –40°C to +85°C (industrial)
	V	= –40°C to +105°C (extended industrial or automotive (AEC-Q100 grade 2))
Package:	4PB	= TFBGA240
	6GW	= TFBGA256
Software License Level:	Blank	= Standard
	SL1	= Level 1
	SL2	= Level 2
	SL3	= Level 3
Pattern:	Blank	= Standard device
	VAO	= Automotive flow/material without PPAP. Available upon request.
	Vxx	= Automotive flow/material with associated PPAP. Available upon request.

Note: The Tape and Reel identifier and the Software License Level identifier only appear in the catalog part number description. These identifiers are used for ordering purposes and are not printed on the device package. Check with your Microchip Sales Office for package availability.

4. Marking

Top marking follows the scheme below:

with possible values:

Line	Description	Values
1	Company logo	Microchip logo
2	Company name	Microchip
3	Device name	SAM9X70 SAM9X72 SAM9X75
4	Temperature code / Packaging code, Jedec symbol	I/4PB e8 V/4PB e8 V/6GW e8
5	Lot traceability, Arm logo	YYWWNNN ARM

5. Configuration Summary

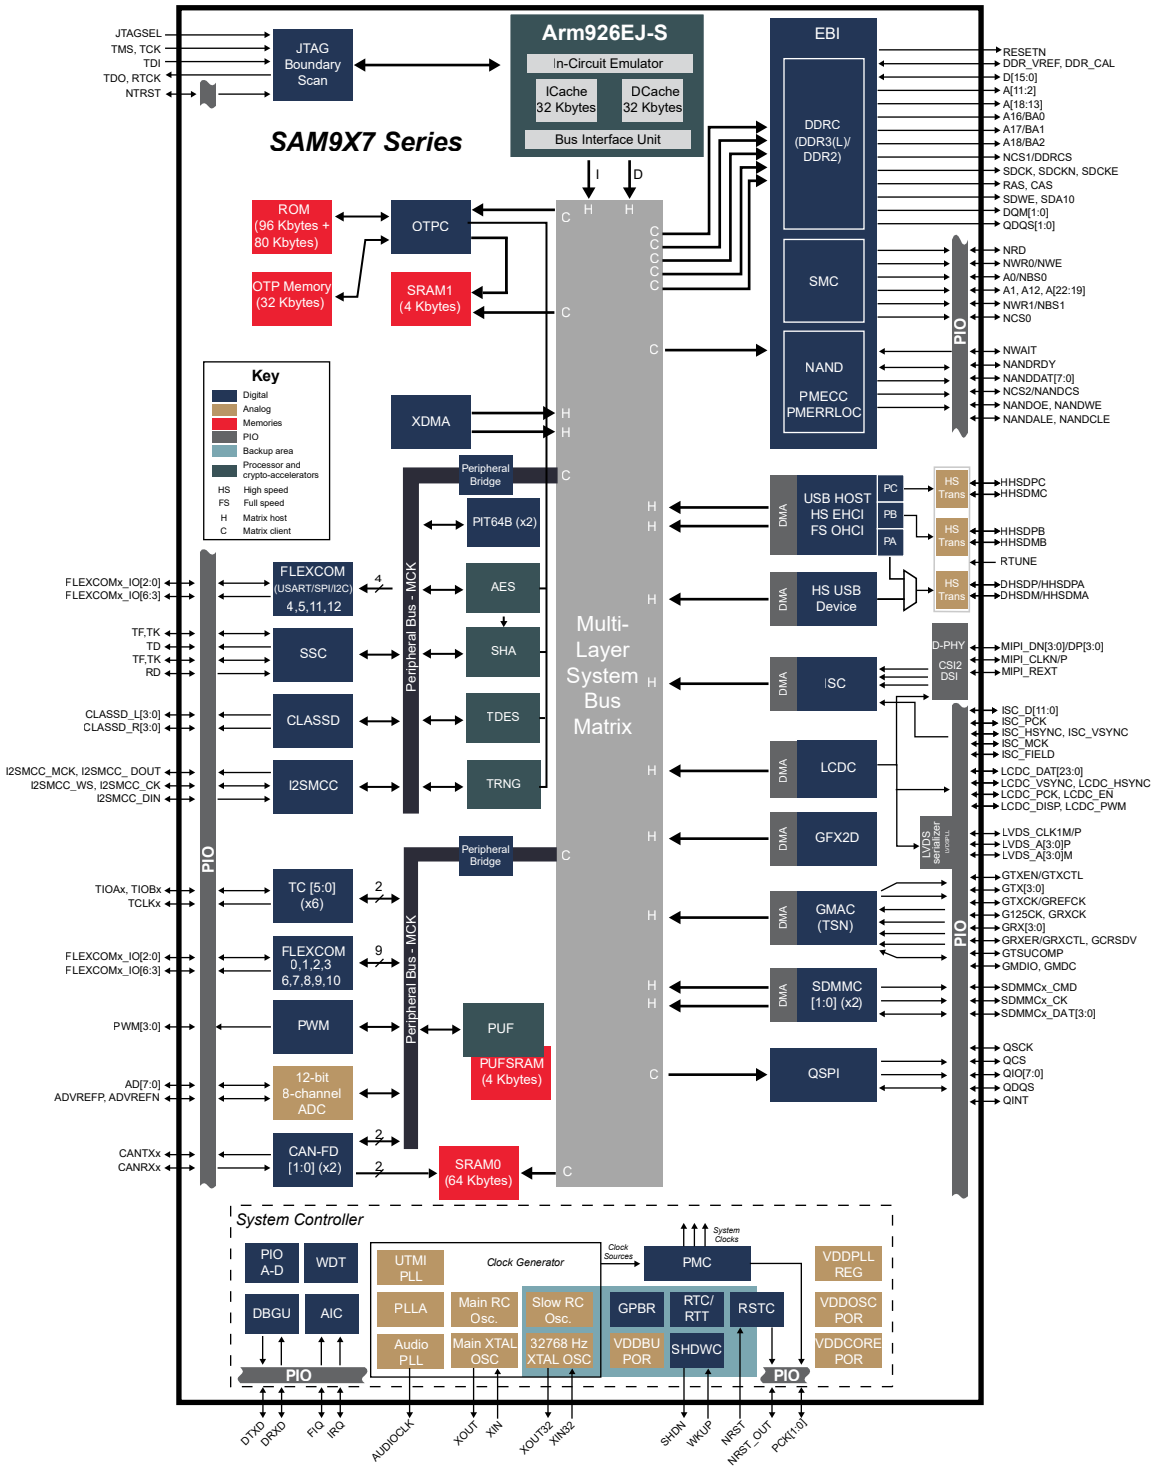

Table 5.1. SAM9X7 Series Configuration Summary

Feature	SAM9X70	SAM9X72	SAM9X75
Package	11x11 mm^2, 0.65-mm pitch, 240-ball BGA		
	9x9 mm^2, 0.5-mm pitch, 256-ball BGA		
Core	Arm926EJ-S @ 800 MHz		
SMC	Up to 16 bits		
MIPI D-PHY	No		Bidirectional, 4 lanes
PIOs	106		
SRAM0/SRAM1	64/4 Kbytes		
Quad/Octal SPI	1		
LCD, GFX2D	No	LVDS, parallel port	LVDS, MIPI DSI, parallel port
Camera Interface (ISC)	Parallel port		MIPI CSI2, parallel port
GMAC	10/100/1000 Mbps with IEEE-1588 and TSN support		
CAN-FD	No	2	
USB	3 (3 hosts or 2 hosts/1 device)		
UART/SPI/I2C	13		
SDIO/SD/MMC	2		
I2SMCC/SSC/CLASSD	1/1/1		
ADC Inputs	8 (8 channels)		
64-bit/32-bit Timer Counter Channels	2/6		
PWM	4 (PWMC)		
Cryptography	AES/TDES/SHA/TRNG

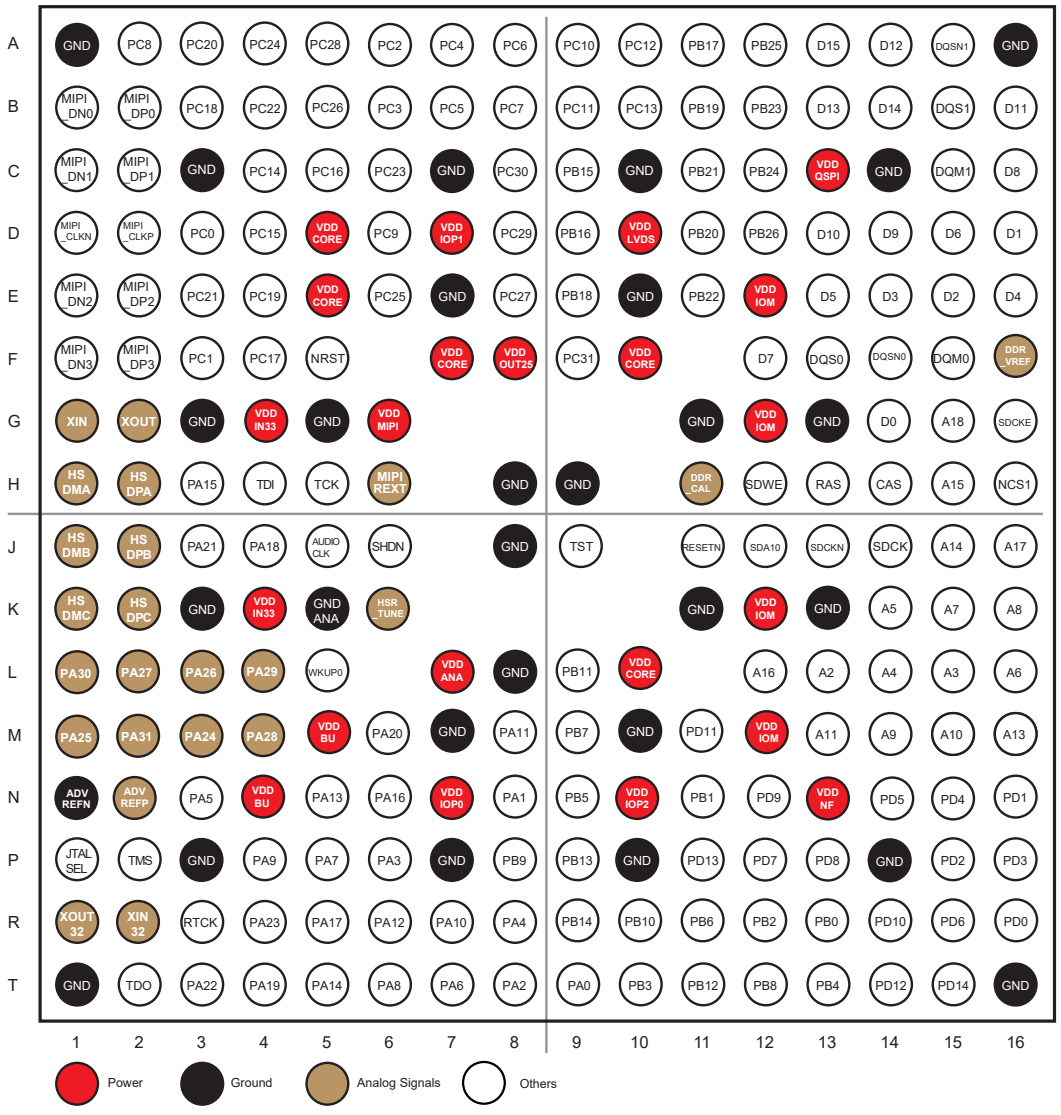
8. Package and Pinout

8.1. Package

SAM9X7 Series devices are available in the following packages.



Package Name	Ball Count	Ball Pitch	Package Size
TFBGA240	240	0.65 mm	11 x 11 x 1.217 mm
TFBGA256	256	0.5 mm	9 x 9 x 1.2 mm

For further details, refer to Mechanical Characteristics.

8.2. Pinout

8.2.1. BGA240 Pinout

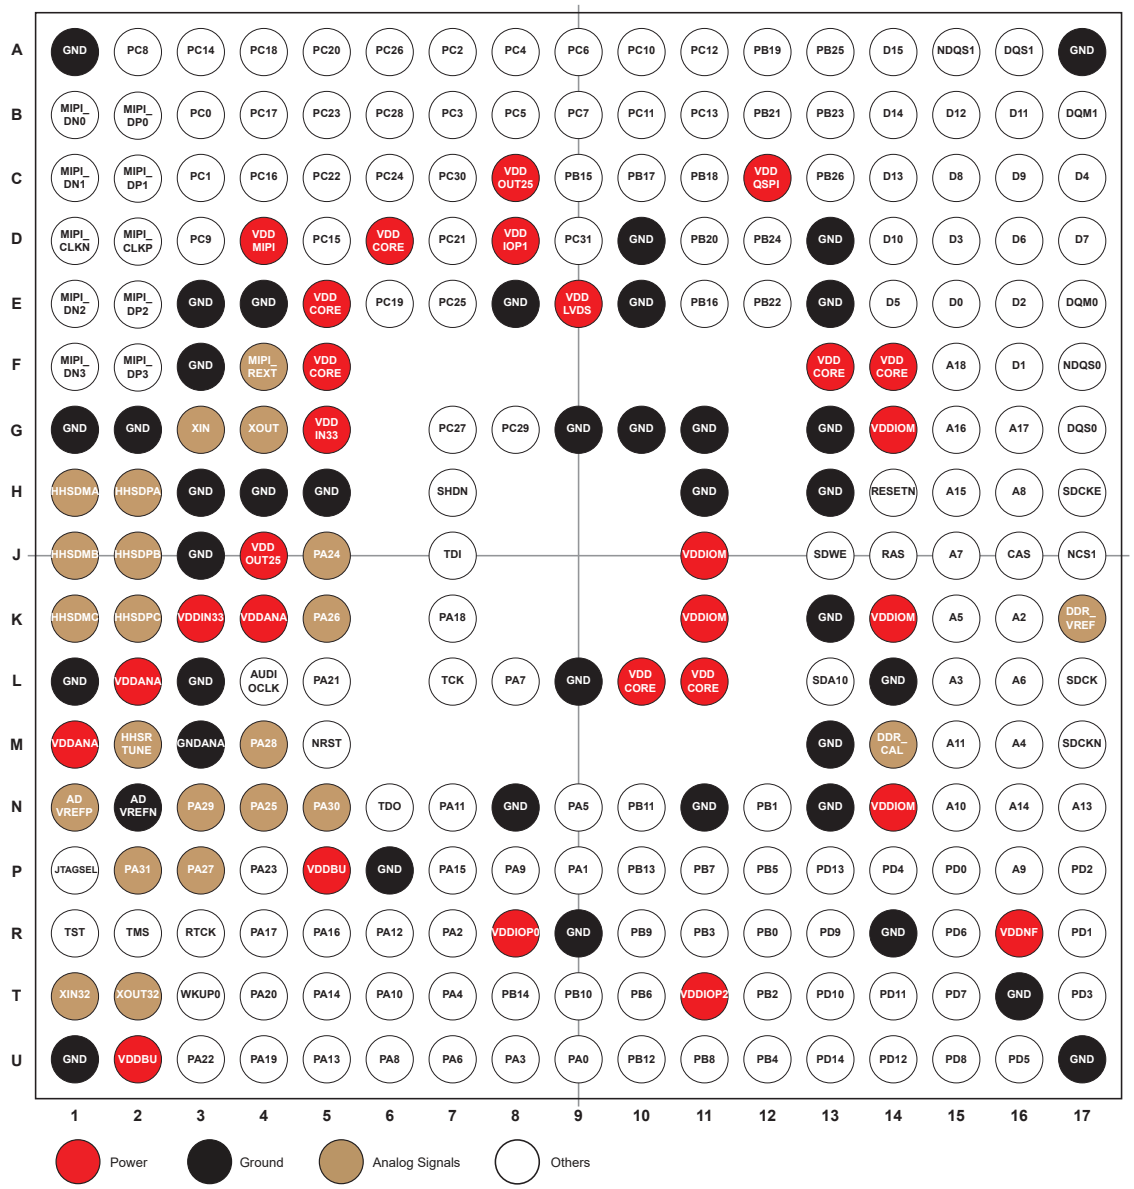


Figure 8.1. SAM9X7 Series BGA240 Pinout

© 2026 Microchip Technology Inc. and its subsidiaries

8.2.2. BGA256 Pinout

Figure 8.2. SAM9X7 Series BGA256 Pinout

8.2.3. Pin Description

The device features several PIO controllers that multiplex the I/O lines of the peripheral set. The following Pin Description table defines how the I/O lines are multiplexed on the different PIO controllers. The "Reset State" column shows whether the PIO line resets in I/O mode or in Peripheral mode. If I/O is shown, the PIO line resets with the characteristics (input, output, pull-up or pull-down) indicated in this same column, so that the device is configured in a known state as soon as the reset is released. As a result, PIO_CFGR.FUNC resets to '0'. If a signal name is shown in the "Reset State" column, the PIO line is assigned to this function and PIO_CFGR.FUNC is not set to '0'. That is the case for pins controlling memories, in particular address lines, which require the pin to be driven as soon as the reset is released.

Notes:

1. When using an I/O line with the Analog-to-Digital Converter (ADC), the PIO line configuration (pull-up, pull-down) programmed before assigning this line to the ADC peripheral is not modified by this peripheral.
2. Refer to the Electrical Characteristics section for further details.
3. I/Os for each peripheral are grouped into I/O sets, listed in the column "I/O Set". For all peripherals, use I/Os that belong to the same I/O set. Timings can be unpredictable when I/Os from different I/O sets are mixed.
4. Signal = 'PIO' if GPIO; Dir = Direction; PU = Pull-up; PD = Pull-down; HiZ = High impedance; ST = Schmitt Trigger
5. On SAM9X70 and SAM9X72: to be tied to GND.

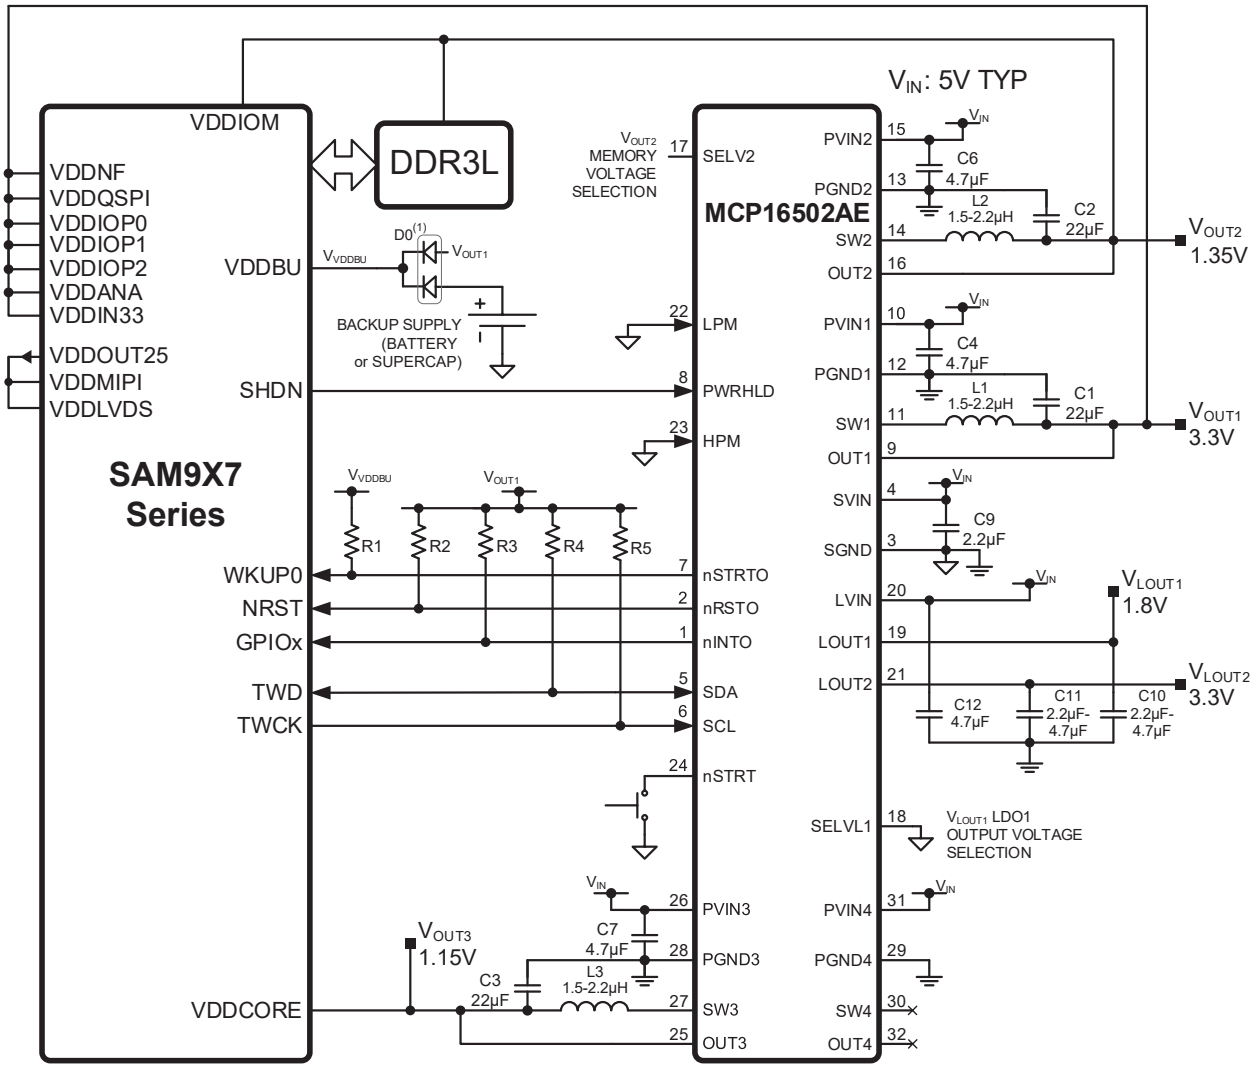
9. Microchip Recommended Power Management Solutions

MCP16502 and MCP16501 are multi-channel Power Management Integrated Circuits (PMICs) recommended for the SAM9X7 series.

9.1. MCP16502 PMIC

MCP16502 features four 1A DC-DC buck regulators and two 0.3A auxiliary LDO regulators, and provides a comprehensive interface to the MPU, which includes an interrupt flag and a 1-MHz I²C interface.



The PMIC-processor interface is optimized so that it remains leakage-free in Backup mode. The following figure shows an application schematic example of a SAM9X7 device with a DDR3L-SDRAM system, powered by MCP16502**AE**. This variant is specifically tailored for SAM9X7 systems with CPU frequency up to 800 MHz. The 3.3V, 1.35V and 1.15V supply rails are fed from DC-DC converters for maximum efficiency. The fourth DC-DC converter (Buck4) of MCP16502**AE** is left off by default during start-up and its components may be removed, if not needed for other purposes.

The two LDO regulator outputs LOUT1 and LOUT2 are auxiliary power rails available for the application. LOUT1 output is on by default at power-up and its default voltage is set to 1.8V, 2.5V or 3.3V depending on the SELV1 pin connection. Buck4 and LOUT2, off by default at power-up, can be started by software through the I²C control bus to the necessary voltage.

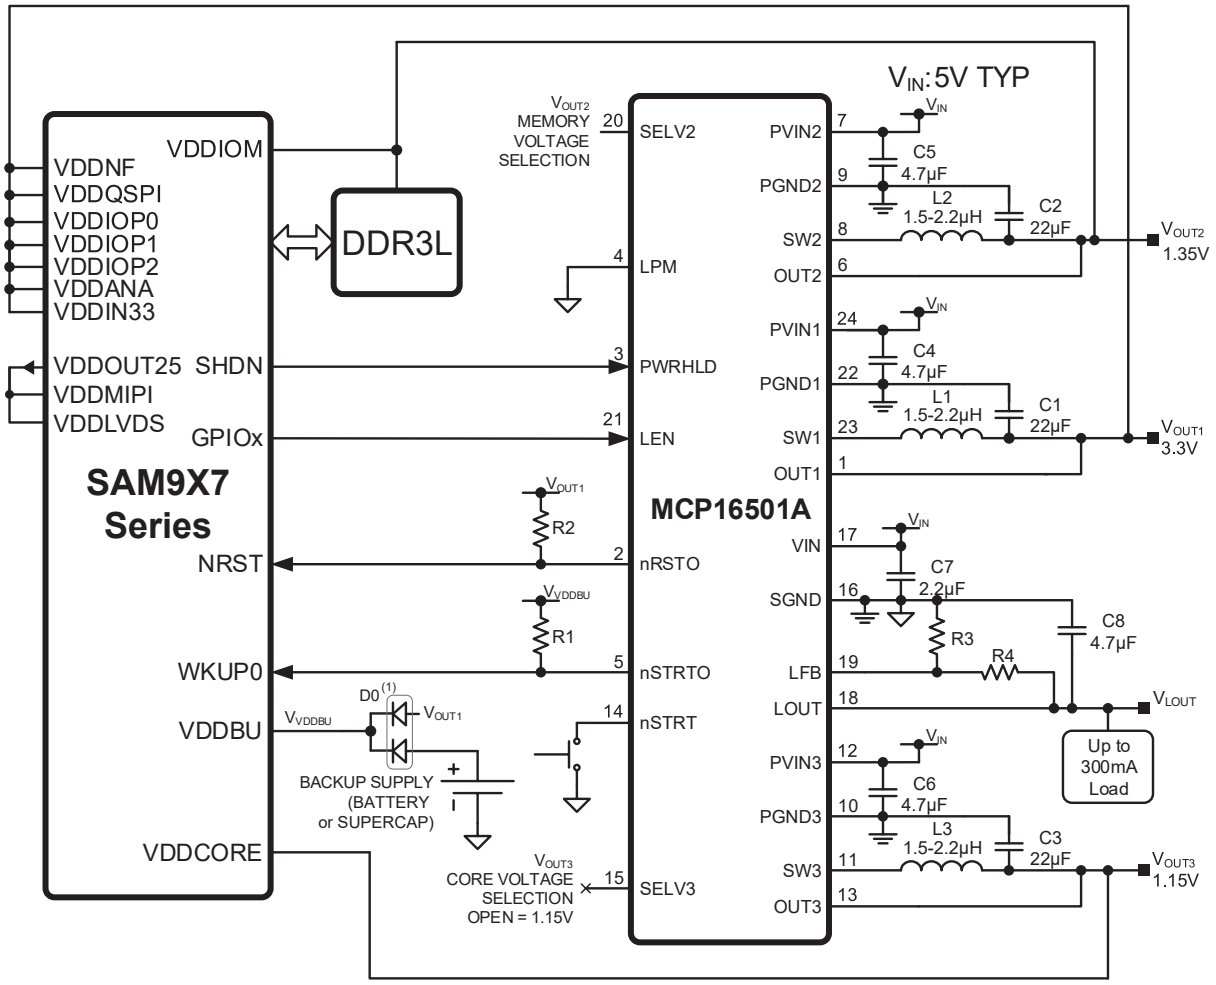
For further details, refer to the MCP16502 documentation on www.microchip.com.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 9.1. MCP16502 Simplified Application Block Diagram

Note: The D0 diode implements a wired-OR function to ensure that VDDBU remains supplied even when the backup supply is depleted. The SAM9X7 Series device cannot operate if VDDBU is outside the specified operating range. This schematic is provided as an example implementation and can be adapted to meet specific application requirements.

9.2. MCP16501 PMIC



MCP16501 is a 4-channel PMIC designed for PCB area constrained applications. In a 4x4mm QFN24 package, it features three 1A DC-DC buck regulators and one 0.3A auxiliary LDO regulator, and provides a simple, leakage-free interface with SAM9X7.

The following figure shows an application schematic example of a SAM9X7 device with a DDR3L-SDRAM system, powered by MCP16501**A**. This variant is specifically tailored for SAM9X7 systems with CPU frequency up to 800 MHz. The 3.3V, 1.35V and 1.15V supply rails are fed from DC-DC converters for maximum efficiency. The LDO regulator output LOUT is controlled with the LEN input and its output voltage is set with the resistive divider R3/R4.

For further details, refer to the MCP16501 documentation on www.microchip.com.

10. Safety and Security Features

10.1. Design for Safety and IEC60730 Class B Certification

10.1.1. Background Information

The IEC 60730 standard encompasses all aspects of appliance design. Annex H of the standard covers the aspects most relevant to microcontrollers. It details the tests and diagnostics which are intended to ensure safe operation of embedded control hardware and software. IEC 60730 defines three classifications for electronic control functions:

- Class A - Control functions which are not intended to be relied upon for safety of the equipment
- Class B - Control functions intended to prevent unsafe operation of the controlled equipment
- Class C - Control functions intended to prevent special hazards such as explosions

Specific design techniques have been used in the SAM9X7 to ease compliance with the IEC 60730 Class B Certification and to resolve general-purpose safety concerns. This allows reduced software development and code size as well as savings on external hardware circuitry, since built-in self-tests are already embedded in the MPU. Table 10.1 provides the list of peripherals which incorporate these techniques, and details whether these features are applicable for the IEC 60730 Class B Certification or for general-purpose safety considerations.

10.2. Design for Security

The SAM9X7 embeds peripherals with security features to prevent counterfeiting, to secure external communication, and to authenticate the system.

Table 10.2 provides the list of peripherals and an overview of their security function. For more information, refer to the sections on each peripheral.

10.3. Safety and IEC 60730 Features

Table 10.1. Safety and IEC 60730 Features

Peripheral	Component	Fault/Error/Feature	Requirements for Class B IEC 60730(1)	General Safety
PMC	Clock	MCK frequency monitor - MCK out-of-range operation	–	X
		32.768 kHz crystal oscillator frequency monitor - Abnormal frequency deviation	X	X
		Main crystal oscillator failure detector - Crystal failure detection	X	X
System Controller	All	Safety critical peripherals and/or counters are fed by the always-on slow RC oscillator - WDT, RSTC, start-up counters, timeout counters, etc.	–	X
PIOC	I/O lines	Digital I/O - Plausibility check	X	–
ADCC		Analog I/O and ADC converter - Plausibility check	X	–
NAND Flash Controller ECC	Memory	Non-volatile memory - Multiple error detection (2 to 24)	–	X

© 2026 Microchip Technology Inc. and its subsidiaries

Table 10.1. Safety and IEC 60730 Features (continued)

Peripheral	Component	Fault/Error/Feature	Requirements for Class B IEC 60730[1]	General Safety
WDT, RSTC	Watchdog	Watchdog is driven by an internal always on clock - Program counter stuck at faults	X	X
		Watchdog configuration can be locked until the next reset - Errant writes (programming errors, errors introduced by system or hardware failures)	–	X
		Watchdog overflow generates a system reset	X	X
Arm926EJ-S MMU	Memory Management Unit	Arm926EJ-S Memory Management Unit	–	X
MATRIX, AIC, RTC, RTT, RSTC, SHDWC, SDRAM, PMC, PIOC, MPDDRC, SMC, CLASSD, SSC, FLEXCOM, QSPI, TC, I2SMCC, ADC	Peripherals	Configuration, Interrupt Enable/ Disable, Control registers can be independently write-protected - Errant writes (programming errors, errors introduced by system or hardware failures)	–	X
AES, TDES, SHA, PIT64B, TC, MPDDRC	Peripherals	Embedded integrity checker with reports in status registers	–	X

Note:

1. Class B IEC 60730 Requirements. Annex H - Table H.1 (H.11.12.7 in Edition 3).

10.4. Security Features

Table 10.2. Security Features

Peripheral	Function	Description	Comments
Arm926EJ-S MMU	Memory Management Unit	Memory Management Unit	–
PIO	I/O Control/ Peripheral Access	When a peripheral is not selected (PIO-controlled), I/O lines have no access to the peripheral.	–
AES	Cryptography Standards	Hardware-accelerated AES up to 256 bits	FIPS-compliant
SHA		SHA up to 512 and HMAC-SHA	
TDES		Hardware-accelerated Triple DES	
TRNG		True Random Number Generator	
AES, TDES	Cryptography Tamper	Immediate clear of keys in case of external tamper event detection (if enabled)	–
AES, TDES, SHA	Cryptography Integrity Checks	AES/TDES/SHA embed integrity checks on configuration registers and algorithm circuitries and a specific flag in status register. If this specific flag is set, an integrity error has been detected. This can occur only on abnormal operating conditions (electromagnetic attacks, VDD glitches, etc.)	–

© 2026 Microchip Technology Inc. and its subsidiaries

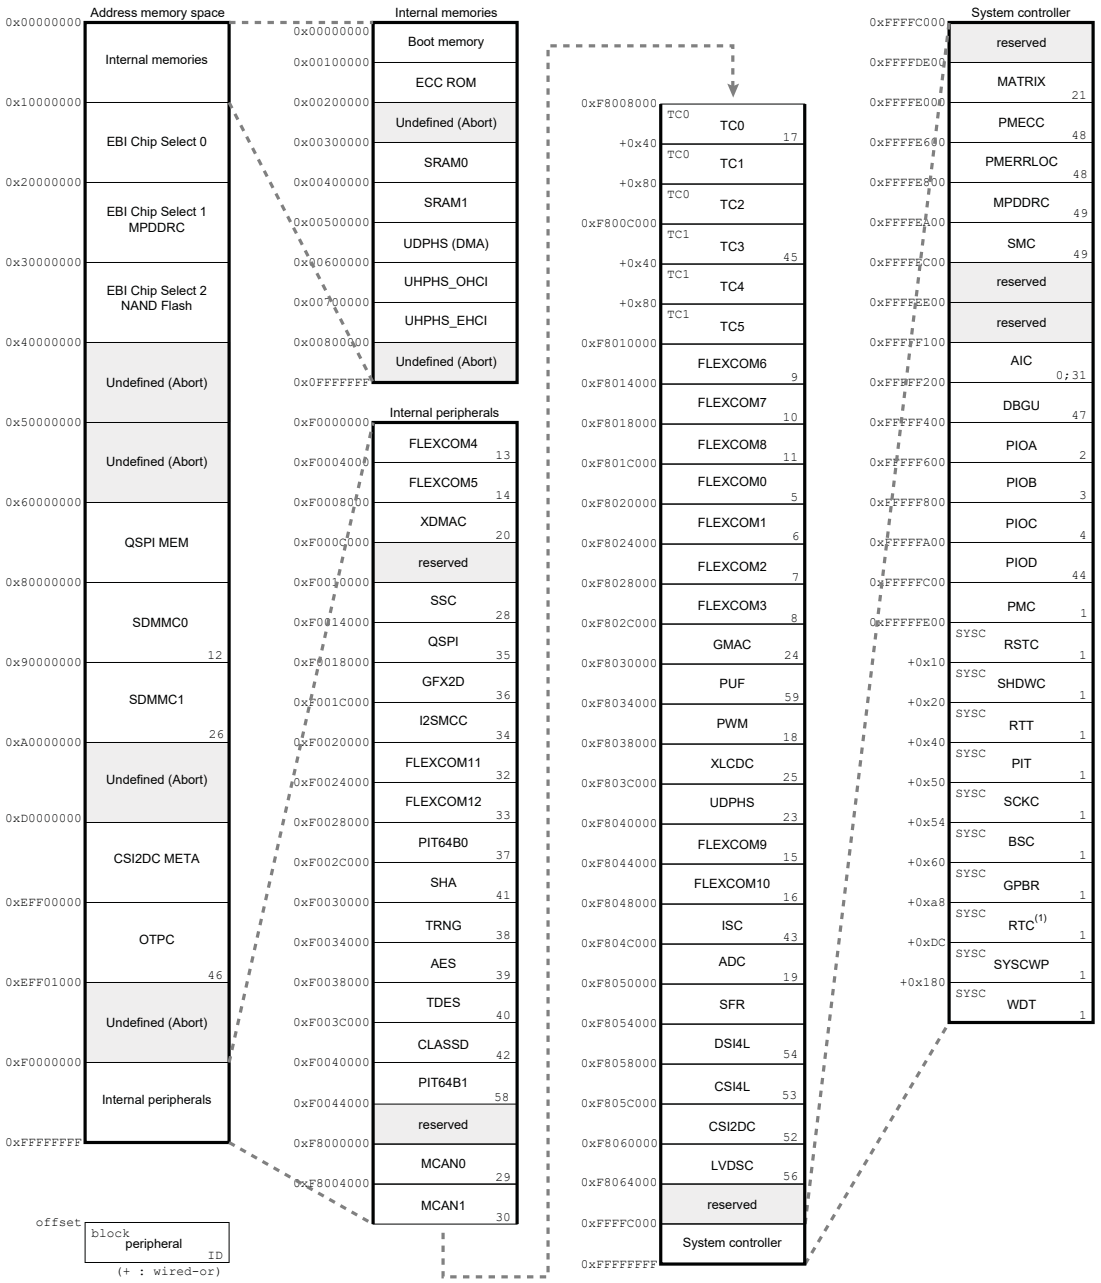

Table 10.2. Security Features (continued)

Peripheral	Function	Description	Comments
OTPC, AES, TDES, TRNG	Cryptography Private Key Bus	Capability to transfer a key to AES/TDES in a totally invisible manner from software	–
Secure Boot	Secure Boot	Code encrypted/decrypted, Trusted Code Authentication	Hardware SHA (HMAC) + Software RSA or AES Hardware (CMAC)
Memories	Scrambling	On-the-fly scrambling/ unscrambling for memories	All external memories such as QSPI, DDR, and all memories on SMC
Physical Unclonable Function	Key Generation	Key creation, derivation, wrapping and management	Includes NIST SP 800-90B compliant DRNG
RTC	IO Tamper Pin	Eight tamper detection pins	VDDCORE WKUP1 to WKUP8 pins can be selected as a source of tamper, performing an immediate clear of AES/TDES keys (if enabled), immediate clear of scrambling keys in DDR/QSPI/ SMC, and immediate clear of General Purpose Backup Registers (if enabled)
	Timestamping	Timestamping of tamper events	All events are logged in the RTC. Timestamping provides the source of the reset/erase memory/interruption
	Configuration	Protection against bad configuration (invalid entry for date and time are impossible)	–
	Glitch Robustness	Glitch on 32 KHz does not corrupt the downstream counters	Glitch on 32 KHz can only create a phase shift of the downstream counters
	Integrity Check	If RTC Status flag TDERR is set, counters integrity have been corrupted	–
Secure OTP	JTAG Access Control	Disable JTAG access by OTP bit	–
PIT64B, TC	Integrity Checks	PIT64B/TC embed integrity checks on configuration registers and algorithm circuitries and a specific flag in status register. If this specific flag is set, an integrity error has been detected. This can occur only on abnormal operating conditions (electromagnetic attacks, VDD glitches, etc.)	–
GPBR	Access Protection	GPBR can be write-protected and/or read-protected	–
	Tamper	GBPR can be immediately cleared on tamper detection (if enabled)	–

CPU and Interconnect

13. Arm926EJ-S Processor

The Arm926EJ-S processor is a member of the Arm9™ family of general-purpose microprocessors. The Arm926EJ-S implements Arm architecture version 5TEJ and is targeted at multi-tasking applications where full memory management, high performance, low die size and low power are important features.

The Arm926EJ-S processor supports the 32-bit Arm and 16-bit Thumb instruction sets, enabling the user to trade off between high performance and high code density. It also supports the 8-bit Java instruction set and includes features for efficient execution of Java bytecode, providing a Java performance similar to JITs (Just-In-Time compilers), for the next generation of Java-powered wireless and embedded devices. It includes an enhanced multiplier design for improved DSP performance.

The Arm926EJ-S processor supports the Arm debug architecture and includes logic to assist in both hardware and software debug.

The Arm926EJ-S provides a complete high performance processor subsystem, including:

- an Arm9EJ-S™ integer core,
- a Memory Management Unit (MMU),
- separate instruction and data AMBA AHB bus interfaces,
- a 32-Kbyte L1 instruction cache and a 32-Kbyte data cache.

For information on the Arm926EJ-S processor, refer to the ARM926EJ-S Technical Reference Manual on www.arm.com.

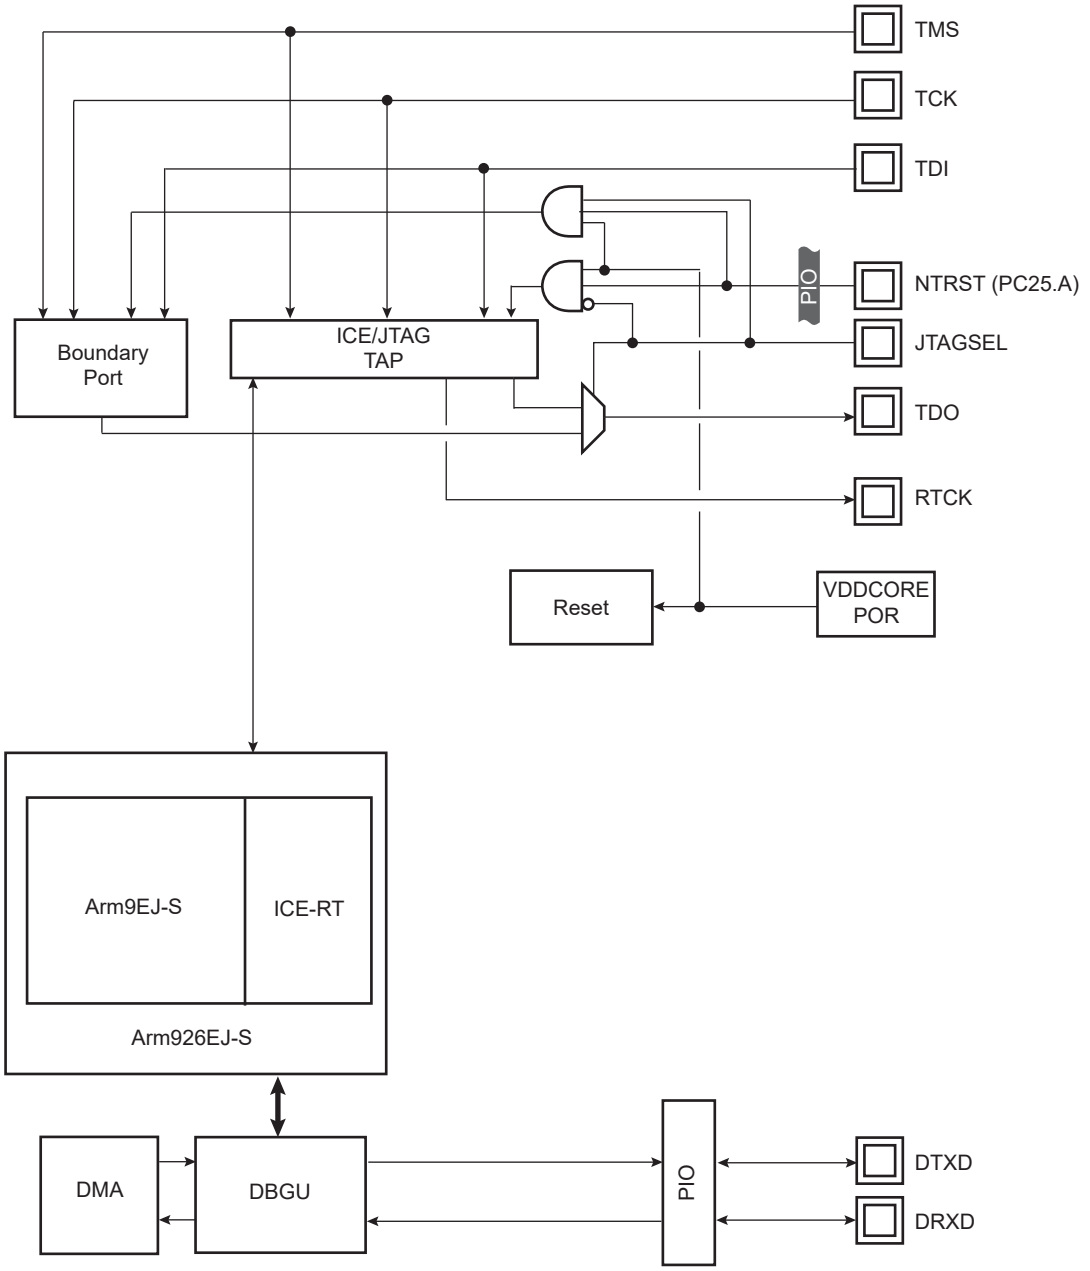
14. Debug and Test

14.1. Description

The product features a number of complementary debug and test capabilities. A common JTAG/ICE (In-Circuit Emulator) port is used for standard debugging functions, such as downloading code and single-stepping through programs. The Debug Unit provides a two-pin UART that can be used to upload an application into the internal SRAM. It manages the interrupt handling of the internal COMMTX and COMMRX signals that trace the activity of the Debug Communication Channel.

A set of dedicated debug and test input/output pins provides a direct access to these capabilities from a PC-based test environment.



14.2. Embedded Characteristics

- Arm926 Real-Time In-Circuit Emulator
  - Two real-time watchpoint units
  - Two independent registers: Debug Control register and Debug Status register
  - Test access port accessible through JTAG protocol
  - Debug communications channel
- Debug Unit
  - Two-pin UART
  - Debug Communication Channel interrupt handling
  - Chip ID register
- IEEE® 1149.1 JTAG Boundary Scan on All Digital Pins

14.6. Functional Description

14.6.1. EmbeddedICE™

The Arm9EJ-S EmbeddedICE-RT is supported via the ICE/JTAG port. It is connected to a host computer via an ICE interface. Debug support is implemented using an Arm9EJ-S core embedded within the Arm926EJ-S. The internal state of the Arm926EJ-S is examined through an ICE/JTAG port which allows instructions to be serially inserted into the pipeline of the core without using the external data bus. Therefore, when in Debug state, a store-multiple (STM) can be inserted into the instruction pipeline. This exports the contents of the Arm9EJ-S registers. This data can be serially shifted out without affecting the rest of the system.

There are two scan chains inside the Arm9EJ-S processor which support testing, debugging, and programming of the EmbeddedICE-RT. The scan chains are controlled by the ICE/JTAG port.

EmbeddedICE mode is selected when JTAGSEL is low. It is not possible to switch directly between ICE and JTAG operations. A chip reset must be performed after JTAGSEL is changed.

For further details on the EmbeddedICE-RT, refer to the ARM9EJ-S Technical Reference Manual (DDI 0222) on www.arm.com.

14.6.2. JTAG Signal Description

TMS is the Test Mode Select input which controls the transitions of the test interface state machine.

TDI is the Test Data Input line which supplies the data to the JTAG registers (Boundary Scan register, Instruction register or other data registers).

TDO is the Test Data Output line which is used to serially output the data from the JTAG registers to the equipment controlling the test. It carries the sampled values from the boundary scan chain (or other JTAG registers) and propagates them to the next chip in the serial test circuit.

NTRST (optional in IEEE Standard 1149.1) is a Test-ReSeT input mandatory in Arm cores and used to reset the debug logic. On Microchip Arm926EJ-S-based cores, NTRST is a Power-on Reset output. It is asserted on power-on. If necessary, the user can also reset the debug logic with the NTRST pin assertion during 2.5 MCK periods.

TCK is the Test ClocK input which enables the test interface. TCK is pulsed by the equipment controlling the test and not by the tested device. It can be pulsed at any frequency. Note the maximum JTAG clock rate on Arm926EJ-S cores is 1/6th the clock of the CPU. This gives 5.45 kHz maximum initial JTAG clock rate for an Arm9E running from the 32.768 kHz slow clock.

© 2026 Microchip Technology Inc. and its subsidiaries

RTCK is the Return Test Clock. This return signal (non-IEEE Standard 1149.1) improves clock handling by emulators. From some ICE interface probes, it can be used to synchronize the TCK clock and it does not care about the given ratio between the ICE interface clock and system clock equal to 1/6th. The RTCK signal is available in JTAG ICE mode only (not in Boundary Scan mode).

14.6.3. Debug Unit

The Debug Unit manages the interrupt handling of the COMMTX and COMMRX signals coming from the ICE and tracing the activity of the Debug Communication Channel. The Debug Unit is used to block access to the system through the ICE interface.

For further details on the Debug Unit, refer to Debug Unit (DBGU).

14.6.4. IEEE 1149.1 JTAG Boundary Scan

IEEE 1149.1 JTAG Boundary Scan allows pin-level access independent of the device packaging technology.

IEEE 1149.1 JTAG Boundary Scan is enabled when JTAGSEL and NTRST are high. The SAMPLE, EXTEST and BYPASS functions are implemented. In ICE Debug mode, the Arm processor responds with a non-JTAG chip ID that identifies the processor to the ICE system. This is not IEEE 1149.1 JTAG-compliant.

It is not possible to switch directly between JTAG and ICE operations. A chip reset must be performed after JTAGSEL is changed.

A Boundary Scan Descriptor Language (BSDL) file is provided to set up test.

15. Bus Matrix (MATRIX)

15.1. Description

The Bus Matrix (MATRIX) implements a multi-layer AHB, based on the AHB-Lite protocol, that enables parallel access paths between multiple hosts and clients in a system, thus increasing the overall bandwidth.

The MATRIX interconnects 14 hosts to 12 clients. The normal latency to connect a host to a client is one cycle, except for the default host of the accessed client which is connected directly (zero cycle latency).

The MATRIX user interface is compliant with the Arm Advanced Peripheral Bus.

15.1.1. MATRIX Hosts

The MATRIX manages the 14 hosts listed in the table below. Each host can perform an access, concurrently with others, to an available client. The MATRIX operates at the main system bus clock (MCK) frequency. Each host has its own decoder, which is defined specifically for each host. In order to simplify the addressing, all the hosts have the same decodings.

Table 15.1. List of MATRIX Hosts

Host No.	Description
0	ISC DMA with QoS support
1	LCDC DMA with QoS support
2	GMAC DMA
3, 4	XDMA controller with QoS support
5	GFX2D DMA
6	SDMMC0 DMA
7	SDMMC1 DMA
8	USB high-speed device port (UDPHS) DMA
9	USB high-speed host port (UHPHS) EHCI DMA
10	USB high-speed host port (UHPHS) OHCI DMA
11	Reserved
12	Arm926 instruction
13	Arm926 data

15.1.2. MATRIX Clients

The MATRIX manages the 12 clients listed in the table below. Each client has its own arbiter, providing a dedicated arbitration per client.

Table 15.2. List of MATRIX Clients

Client No.	Description
0	MPDDRC port 4 with QoS support
1	EBI/MPDDRC port 0
2	MPDDRC port 1
3	MPDDRC port 2
4	MPDDRC port 3
5	SRAM0
6	OTPC client interface (ROM and OTP memory)
7	CSI2DC
8	APB 0

Table 15.2. List of MATRIX Clients (continued)

Client No.	Description
9	APB 1
10	QSPI
11	UDPHS dual port RAM
	UHPHS OHCI configuration registers
	UHPHS EHCI configuration registers
	SDMMC0 configuration registers
	SDMMC1 configuration registers
	SRAM1 port 1

Notes:

- APB0 is running @ MCK (up to 266 MHz) and includes TC0-1, FLEXCOM1,2,3,6,7,8,9,10, PWM, ADC, CAN0-1, PUF
- APB1 is running @ MCK (up to 266 MHz) and includes high-performance peripherals: SSC, CLASSD, I2SMCC, TRNG, TDES, SHA, AES PIT64B0-1, FLEXCOM4,5,11,12

15.1.3. Host to Client Access

MATRIX interconnections are versatile and can be modified depending on MPDDRC multiport configuration and NAND Flash usage.

15.1.3.1. MATRIX Configuration for MPDDRC Single Port Setting (Default)

The default configuration is single port, with all devices accessed on D0-D15: SDRAM and/or NAND Flash and/or SMC. This configuration is the Reset state SFR_CCFG_EBICSA.DDR_MP_EN = 0.

As the DDRC multiport feature is disabled, all hosts access DDR-SDRAM using MATRIX Client 1 (MPDDRC port 0), sharing it with EBI accesses.

The NAND Flash can be located either on D0-D7 or on D16-D23 depending on SFR_CCFG_EBICSA.NFD0_ON_D16, respectively 0 (default) or 1.

Table 15.3. MATRIX Interconnections with MPDDRC Single Port Configuration (Default)

Hosts		0	1	2	3	4	5	6	7	8	9	10	11	12	13

15.1.3.2.MATRIX Configuration for MPDDRC Multiport Setting

If the NAND Flash is located on D16-D23, the MPDDRC multiport feature can be enabled. The NAND Flash has its own dedicated port (Client 1) and other peripherals are distributed across four other MATRIX clients (0, 2, 3 and 4), respectively on DDR ports 4, 1, 2 and 3.

This configuration is achieved by setting the bits SFR_CCFG_EBICSA.NFD0_ON_D16 and SFR_CCFG_EBICSA.DDR_MP_EN.

By default, the round-robin arbitration scheme is enabled in MPDDRC. If the system is latency-sensitive, the quality of service (QoS) policy can be enabled in MPDDRC by setting MPDDRC_CONF_ARBITER.ARB to 3.

Table 15.4. MPDDRC Port MATRIX Interconnections with MPDDRC Multiport Configuration

Hosts		0	1	2	3	4	5	6	7	8	9	10	11	12	13
Clients		ISC DMA	XLCDC DMA	GMAC DMA	XDMAC IF0	XDMAC IF1	GFX2D	SDMMC0 DMA	SDMMC1 DMA	UDPHS DMA	UHPHS EHCI	UHPHS OHCI	Reserved	Arm926 Instruc.	Arm926 Data
0	MPDDRC port 4	✓	✓	✓	–	–	–	–	–	–	–	–	–	–	–
1	NAND Flash	–	–	–	✓	✓	–	–	–	–	–	–	–	✓	✓
	MPDDRC port 0	–	–	–	–	–	–	–	–	–	–	–	–	–	–
2	MPDDRC port 1	–	–	–	✓	–	–	✓	–	–	–	–	–	✓	–
3	MPDDRC port 2	–	–	–	–	✓	✓	–	✓	–	–	–	–	–	✓
4	MPDDRC port 3	–	–	–	–	–	–	–	–	✓	✓	✓	–	–	–
5-11	No change														

15.1.3.3.MATRIX Alternate Configurations

If the NAND Flash is located on D16-D23 (SFR_CCFG_EBICSA.NFD0_ON_D16 = 1) and more flexibility is required, an alternate configuration can be achieved with one bit per host to control port distribution.

Configure MPDDRC in single port (SFR_CCFG_EBICSA.DDR_MP_EN = 0) and remap individual ports via the Remap Multiport DDR register (SFR_REMAP_MP_DDR).

© 2026 Microchip Technology Inc. and its subsidiaries

Note: SFR_REMAP_MP_DDR = 14'b11111111111111 is equivalent to MPDDRC multi-port setting with SFR_CCFG_EBICSA.DDR_MP_EN = 1.

Configuration Example

When SFR_REMAP_MP_DDR = 14'b11111111011111, all hosts have a multiport MATRIX client configuration except GFX2D (Host_5), which keeps the single port MATRIX client configuration (MATRIX Client 1).

Performance is increased, since GFX2D uses MATRIX Client 1 (used only for NAND Flash in this configuration), avoiding an arbitration stage with Arm926 data on MATRIX Client 3.

Table 15.5. MPDDRC Port MATRIX Interconnections Example with Dedicated Port Remapping

Hosts		0	1	2	3	4	5	6	7	8	9	10	11	12	13

5-11	No change														

15.2. Embedded Characteristics

- 14 Configurable Host Ports
- 12 Configurable Client Ports
- One Decoder for Each Host
- One Remap Function for Each Host
- Support for Long Bursts of Length 32, 64, 128 and Up to the Limit of 256-bit Burst Beats of Words
- Enhanced Programmable Mixed Arbitration for Each Client
  - Round-robin
  - Fixed priority
  - Latency Quality of Service
- Programmable Default Host for Each Client
  - No default host
  - Last accessed default host
  - Fixed default host
- Deterministic Maximum Access Latency for Hosts
- Zero or One Cycle Arbitration Latency for the First Access of a Burst
- Bus Lock Forwarding to Clients
- Host Number Forwarding to Clients
- Register Write Protection of User Interface Registers

© 2026 Microchip Technology Inc. and its subsidiaries

15.3. Special Bus Granting Techniques

The MATRIX provides some speculative bus granting techniques in order to anticipate access requests from hosts. Hence, latency is reduced at first access of a burst or, for a single transfer, as long as the client is free from any other host access. It does not provide any benefit if the client is continuously accessed by more than one host, since arbitration is pipelined and has no negative effect on the client bandwidth or access latency.

This bus granting technique sets a different default host for every client.

At the end of the current access, if no other request is pending, the client remains connected to its associated default host. A client can be associated with three kinds of default hosts:

- no default host
- last access host
- fixed default host

To change from one type of default host to another, the user interface provides Client Configuration registers (MATRIX_SCFGx), one for every client, which set a default host for each client. MATRIX_SCFGx contain two fields to manage host selection: DEFMSTR_TYPE and FIXED_DEFMSTR. The 2-bit DEFMSTR_TYPE field selects the default host type (no default, last access host, fixed default host), whereas the 4-bit FIXED_DEFMSTR field selects a fixed default host provided that DEFMSTR_TYPE is set to fixed default host. See MATRIX_SCFGx.

15.4. No Default Host

After the end of the current access, if no other request is pending, the client is disconnected from all hosts. This saves power by preventing useless bus activity, in particular when the bus target clock is disabled by software.

This configuration incurs one latency clock cycle for the first access of a burst after bus Idle. Arbitration without default host may be used for hosts that perform significant bursts or several transfers with no Idle cycle in-between, or if the client bus bandwidth is widely used by one or more hosts.

This configuration provides no benefit on access latency or bandwidth when reaching maximum client bus throughput whatever the number of requesting hosts.

15.5. Last Access Host

After the end of the current access, if no other request is pending, the client remains connected to the last host that performed an access request.

This enables the MATRIX to remove the one latency cycle for the last host that accessed the client. Other non-privileged hosts still get one latency clock cycle if they need to access the same client. This technique is useful for hosts that mainly perform single accesses or short bursts with some Idle cycles in-between.

This configuration provides no benefit on access latency or bandwidth when reaching maximum client bus throughput whatever is the number of requesting hosts.

15.6. Fixed Default Host

After the end of the current access, if no other request is pending, the client connects to its fixed default host. Unlike the last access host, the fixed default host does not change unless the user modifies it by software (FIXED_DEFMSTR field of the related MATRIX_SCFG).

This allows the MATRIX arbiters to remove the one latency clock cycle for the fixed default host of the client. All requests attempted by the fixed default host do not cause any arbitration latency, whereas other non-privileged hosts get one latency cycle. This technique is useful for a host that mainly performs single accesses or short bursts with Idle cycles in-between.

© 2026 Microchip Technology Inc. and its subsidiaries

This configuration provides no benefit on access latency or bandwidth when reaching maximum client bus throughput, regardless of the number of requesting hosts.

15.7. Arbitration

The MATRIX provides an arbitration technique that reduces latency when conflicts occur, i.e., when two or more hosts try to access the same client at the same time. One arbiter per client is provided, thus arbitrating each client specifically.

The user can either choose one of the following arbitration types, or mix them for each client:

1. Round-robin Arbitration (default)
2. Fixed Priority Arbitration

The resulting algorithm may be complemented by selecting a default host configuration for each client.

When re-arbitration must be done, specific conditions apply. See Arbitration Scheduling.

15.7.1. Arbitration Scheduling

Each arbiter has the ability to arbitrate between two or more different host requests. In order to avoid burst breaking as well as to provide the maximum throughput for client interfaces, arbitration may only take place during the following cycles:

- Idle Cycles: When a client is not connected to any host or is connected to a host which is not currently accessing it.
- Single Cycles: When a client is currently doing a single access.
- End of Burst Cycles: When the current cycle is the last cycle of a burst transfer. For defined length burst, predicted end of burst matches the size of the transfer but is managed differently for undefined length burst. See Undefined Length Burst Arbitration.
- Slot Cycle Limit: When the slot cycle counter has reached the limit value indicating that the current host access is too long and must be broken. See Slot Cycle Limit Arbitration.

15.7.1.1. Undefined Length Burst Arbitration

In order to prevent long burst lengths that can lock the access to the client for an excessive period of time, the user can trigger the re-arbitration before the end of the incremental bursts. The re-arbitration period can be selected from the following Undefined Length Burst Type (ULBT) possibilities:

- Unlimited: no predetermined end of burst is generated. This value enables 1 Kbyte burst lengths.
- 1-beat bursts: predetermined end of burst is generated at each single transfer during the INCR transfer.
- 4-beat bursts: predetermined end of burst is generated at the end of each 4-beat boundary during INCR transfer.
- 8-beat bursts: predetermined end of burst is generated at the end of each 8-beat boundary during INCR transfer.
- 16-beat bursts: predetermined end of burst is generated at the end of each 16-beat boundary during INCR transfer.
- 32-beat bursts: predetermined end of burst is generated at the end of each 32-beat boundary during INCR transfer.
- 64-beat bursts: predetermined end of burst is generated at the end of each 64-beat boundary during INCR transfer.
- 128-beat bursts: predetermined end of burst is generated at the end of each 128-beat boundary during INCR transfer.

© 2026 Microchip Technology Inc. and its subsidiaries

Undefined-length bursts lower than 8 beats should not be used since this may decrease the overall bus bandwidth due to arbitration and client latencies at each first access of a burst.

However, if the length of undefined-length bursts is known for a host, it is recommended to configure MATRIX_MCFG.ULBT accordingly.

15.7.1.2. Slot Cycle Limit Arbitration

The MATRIX contains specific logic to break long accesses, such as very long bursts on a very slow client (e.g., an external low speed memory). At each arbitration time, a counter is loaded with the value previously written in MATRIX_SCFGx.SLOT_CYCLE and decreased at each clock cycle. When the counter elapses, the arbiter has the ability to re-arbitrate at the end of the current system bus access cycle.

The default reset value of MATRIX_SCFGx.SLOT_CYCLE does not need to be changed.

WARNING This feature cannot prevent any client from locking its access indefinitely.

15.7.2. Arbitration Priority Scheme

The MATRIX arbitration scheme is organized in priority pools, each corresponding to an access criticality class as shown in the “Latency Quality of Service” column in the table below. When the Latency Quality of Service is enabled for a host-client pair through the MATRIX, the priority pool number to use for arbitration at the client port is determined from the host. When the Latency Quality of Service is disabled, it is determined through the MATRIX user interface. See MATRIX_PRASx.

After reset, the Latency Quality of Service is enabled by default on all of the host ports that are connected to a host driving the Latency Quality of Service signals, as shown in the bit LQOSEN of MATRIX_PRASx and MATRIX_PRBSx.

Table 15.6. Arbitration Priority Pools

Priority Pool	Latency Quality of Service
3	Latency Critical
2	Latency Sensitive
1	Bandwidth Sensitive
0	Background Transfers

Round-robin priority is used in the highest and lowest priority pools 3 and 0, whereas fixed level priority is used between priority pools and in the intermediate priority pools 2 and 1.

For each client, each host is assigned to one of the client priority pools based on the Latency Quality of Service inputs or to the priority registers for clients (MxPR fields of MATRIX_PRAS and MATRIX_PRBS). When evaluating host requests, this priority pool level always takes precedence.

After reset, most of the hosts belong to the lowest priority pool (MxPR = 0, Background Transfer) and are therefore granted bus access in a true round-robin order.

The highest priority pool must be specifically reserved for hosts requiring very low access latency. If more than one host belongs to this pool, those hosts are granted bus access in a biased round-robin manner which enables tight and deterministic maximum access latency from system bus requests. In the worst case, any currently occurring high-priority host request is granted after the current bus host access has ended and any other high priority pool host requests have been granted once each.

The lowest priority pool shares the remaining bus bandwidth between hosts.

© 2026 Microchip Technology Inc. and its subsidiaries

Intermediate priority pools enable fine priority tuning. Typically, a latency-sensitive host or a bandwidth-sensitive host use such a priority level. The higher the priority level (MxPR value), the higher the host priority.

For good CPU performance, it is recommended to let the CPU priority configured with the default reset value 2 (Latency Sensitive).

All combinations of MxPR values are allowed for all hosts and clients. For example, some hosts might be assigned the highest priority pool (round-robin), and remaining hosts the lowest priority pool (round-robin), with no host for intermediate fixed priority levels.

15.7.2.1. Fixed Priority Arbitration

The fixed priority arbitration algorithm is the first and only arbitration algorithm applied between hosts from distinct priority pools. It is also used in priority pools other than the highest and lowest priority pools (intermediate priority pools).

Fixed priority arbitration enables the MATRIX arbiters to dispatch the requests from different hosts to the same client by using the fixed priority defined by the user in the MxPR field for each host in the registers, MATRIX_PRAS and MATRIX_PRBS. If two or more host requests are active at the same time, the host with the highest priority MxPR number is serviced first.

In intermediate priority pools, if two or more host requests with the same priority are active at the same time, the host with the highest number is serviced first.

15.7.2.2. Round-Robin Arbitration

This algorithm is only used in the highest and lowest priority pools. It allows the MATRIX arbiters to properly dispatch requests from different hosts to the same client. If two or more host requests are active at the same time in the priority pool, they are serviced in a round-robin increasing host number order.

15.8. Register Write Protection

To prevent any single software error from corrupting MATRIX behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the Write Protection Mode register (MATRIX_WPMR).

If a write access to a write-protected register is detected, the WPVS flag in the Write Protection Status register (MATRIX_WPSR) is set and the field WPVSRC indicates the register in which the write access has been attempted.

The WPVS flag is reset by writing the MATRIX_WPMR with the appropriate access key WPKEY.

The registers listed below can be write-protected.

Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						ULBT[2:0]		
Access						R/W	R/W	R/W
Reset						1	0	0

Bits 2:0 – ULBT[2:0] Undefined Length Burst Type

Value	Name	Description
0	UNLIMITED	Unlimited Length Burst—No predicted end of burst is generated, therefore INCR bursts coming from this host can only be broken if the Client Slot Cycle Limit is reached. If the Slot Cycle Limit is not reached, the burst is normally completed by the host, at the latest, on the next system bus 1 Kbyte address boundary, allowing up to 256-beat word bursts or 128-beat double-word bursts. This value should not be used in the very particular case of a host capable of performing back-to-back undefined length bursts on a single client, since this could indefinitely freeze the client arbitration and thus prevent another host from accessing this client.
1	SINGLE	Single Access—The undefined length burst is treated as a succession of single accesses, allowing re-arbitration at each beat of the INCR burst or bursts sequence.
2	4_BEAT	4-beat Burst—The undefined length burst or bursts sequence is split into 4-beat bursts or less, allowing re-arbitration every 4 beats.
3	8_BEAT	8-beat Burst—The undefined length burst or bursts sequence is split into 8-beat bursts or less, allowing re-arbitration every 8 beats.
4	16_BEAT	16-beat Burst—The undefined length burst or bursts sequence is split into 16-beat bursts or less, allowing re-arbitration every 16 beats.
5	32_BEAT	32-beat Burst—The undefined length burst or bursts sequence is split into 32-beat bursts or less, allowing re-arbitration every 32 beats.
6	64_BEAT	64-beat Burst—The undefined length burst or bursts sequence is split into 64-beat bursts or less, allowing re-arbitration every 64 beats.
7	128_BEAT	128-beat Burst—The undefined length burst or bursts sequence is split into 128-beat bursts or less, allowing re-arbitration every 128 beats. Unless duly needed, the ULBT should be left at its default 0 value for power saving.

15.9.2. MATRIX Client Configuration Register x

Name: MATRIX_SCFGx
Offset: 0x40 + x*0x04 [x=0..11]
Reset: 0x000001FF
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

–

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
			FIXED_DEFMSTR[3:0]				DEFMSTR_TYPE[1:0]	
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
								SLOT_CYCLE[8]
Access								R/W
Reset								1

Bit	7	6	5	4	3	2	1	0
	SLOT_CYCLE[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1

Bits 21:18 – FIXED_DEFMSTR[3:0] Fixed Default Host
This is the number of the Default Host for this client. Only used if DEFMSTR_TYPE is 2. Specifying the number of a host which is not connected to the selected client is equivalent to setting DEFMSTR_TYPE to 0.

Bits 17:16 – DEFMSTR_TYPE[1:0] Default Host Type

Value	Name	Description
0	NONE	No Default Host—At the end of the current client access, if no other host request is pending, the client is disconnected from all hosts. This results in a one clock cycle latency for the first access of a burst transfer or for a single access.
1	LAST	Last Default Host—At the end of the current client access, if no other host request is pending, the client stays connected to the last host having accessed it. This results in not having one clock cycle latency when the last host tries to access the client again.
2	FIXED	Fixed Default Host—At the end of the current client access, if no other host request is pending, the client connects to the fixed host the number that has been written in the FIXED_DEFMSTR field. This results in not having one clock cycle latency when the fixed host tries to access the client again.

Bits 8:0 – SLOT_CYCLE[8:0] Maximum Bus Grant Duration for Hosts
When SLOT_CYCLE system bus clock cycles have elapsed since the last arbitration, a new arbitration takes place to let another host access this client. If another host is requesting the client bus, then the current host burst is broken.

© 2026 Microchip Technology Inc. and its subsidiaries

If SLOT_CYCLE = 0, the Slot Cycle Limit feature is disabled and bursts always complete unless broken according to the ULBT.
This limit has been placed in order to enforce arbitration so as to meet potential latency constraints of hosts waiting for client access.
This limit must not be too small. Unreasonably small values break every burst and the MATRIX arbitrates without performing any data transfer. The default maximum value is usually an optimal conservative choice.
In most cases, this feature is not needed and should be disabled for power saving.
See Slot Cycle Limit Arbitration for details.

Reset		–	–	–		–	–	–

Bits 2, 6, 10, 14, 18, 22, 26, 30 – LQOSENx Latency Quality of Service Enable for Host x

Value	Description
0	Disables propagation of Latency Quality of Service from the Host x to the Client and apply MxPR priority for all access from Host x to the Client.
1	Enables the propagation of Latency Quality of Service from the Host x to the Client if supported by the Host x.

Bits 0:1, 4:5, 8:9, 12:13, 16:17, 20:21, 24:25, 28:29 – MxPR Host x Priority
Fixed priority of Host x for accessing the selected client. The higher the number, the higher the priority.
All the hosts programmed with the same MxPR value for the client make up a priority pool.
Round-robin arbitration is used in the lowest (MxPR = 0) and highest (MxPR = 3) priority pools.

© 2026 Microchip Technology Inc. and its subsidiaries

Fixed priority is used in intermediate priority pools (MxPR = 1) and (MxPR = 2).
See Arbitration Priority Scheme for details.
If LQOSENx bit is cleared, then this priority value is used as it for arbitration and downward propagation to the client. If LQOSENx bit is set, then this priority acts as the upper limit for the Latency Quality of Service from Host x.
For hosts other than the CPU, the usual value of this field should be 0x0 if LQOSENx bit is cleared, and 0x1 if LQOSENx bit is set. For the CPU host, the usual value of this field should be 0x2.

Access	R/W							R/W
Reset	0							0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x4D4154	PASSWD	Writing any other value in this field aborts the write operation of the WPEN and CFGFRZ bits. Always reads as 0.

Bit 7 – CFGFRZ Configuration Freeze

Value	Description
0	The MATRIX configuration is not frozen.
1	Freezes the MATRIX configuration until hardware reset. The registers that can be protected by the WPEN bit and the Write Protection Mode Register are no longer modifiable.

Bit 0 – WPEN Write Protection Enable

See Register Write Protection for the list of registers that can be write-protected.

Value	Description
0	Disables the write protection if WPKEY corresponds to 0x4D4154 (“MAT” in ASCII).
1	Enables the write protection if WPKEY corresponds to 0x4D4154 (“MAT” in ASCII).

© 2026 Microchip Technology Inc. and its subsidiaries

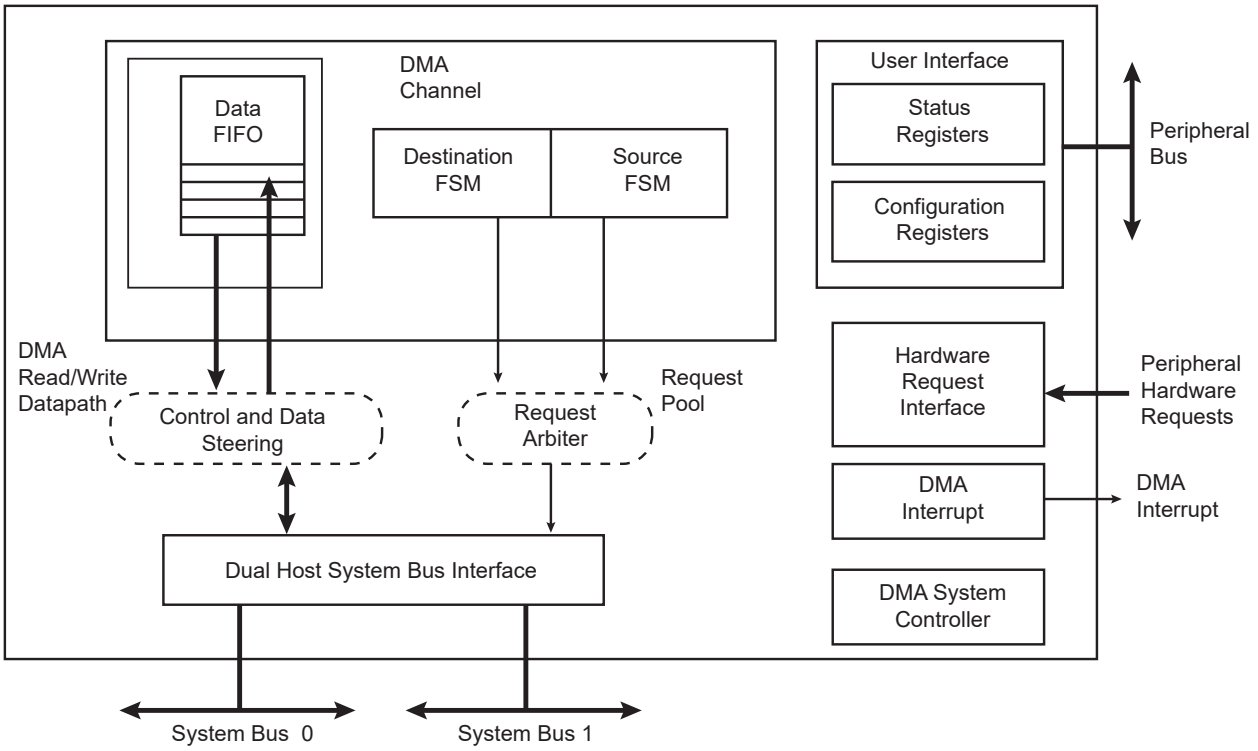
16. DMA Controller (XDMAC)

16.1. Description

The DMA Controller (XDMAC) is a central direct memory access controller. It performs peripheral data transfer and memory move operations over one or two bus ports through the unidirectional communication channel. Each channel is fully programmable and provides both peripheral or memory-to-memory transfers.



16.2. Embedded Characteristics

- 2 System Bus Host Interfaces
- 16 DMA Channels
- 51 Hardware Requests
- 4 Kbytes Embedded FIFO
- Supports Peripheral-to-Memory, Memory-to-Peripheral, or Memory-to-Memory Transfer Operations
- Peripheral DMA Operation Runs on Bytes (8-bit), Half-Word (16-bit) and Word (32-bit)
- Memory DMA Operation Runs on Bytes (8 bit), Half-Word (16-bit) and Word (32 -bit)
- Supports Hardware and Software Initiated Transfers
- Supports Linked List Operations
- Supports Incrementing or Fixed Addressing Mode
- Supports Programmable Independent Data Striding for Source and Destination
- Supports Programmable Independent Microblock Striding for Source and Destination
- Configurable Priority Group and Arbitration Policy
- Programmable AHB Burst Length
- Configuration Interface on Peripheral Bus
- XDMAC Architecture Includes Multiport FIFO
- Supports Multiple View Channel Descriptor
- Automatic Flush of Channel Trailing Bytes
- Automatic Coarse-Grain and Fine-Grain Clock Gating
- Hardware Acceleration of Memset Pattern
- Supports Configurable Quality of Service per Channel

© 2026 Microchip Technology Inc. and its subsidiaries

16.5. Functional Description

16.5.1. Basic Definitions

Source Peripheral: Client device, memory mapped on the interconnection network, from where the XDMAC reads data. The source peripheral teams up with a destination peripheral to form a channel. A data read operation is scheduled when the peripheral transfer request is asserted.

Destination Peripheral: Client device, memory mapped on the interconnection network, to which the XDMAC writes. A write data operation is scheduled when the peripheral transfer request is asserted.

Channel: The data movement between source and destination creates a logical channel.

© 2026 Microchip Technology Inc. and its subsidiaries

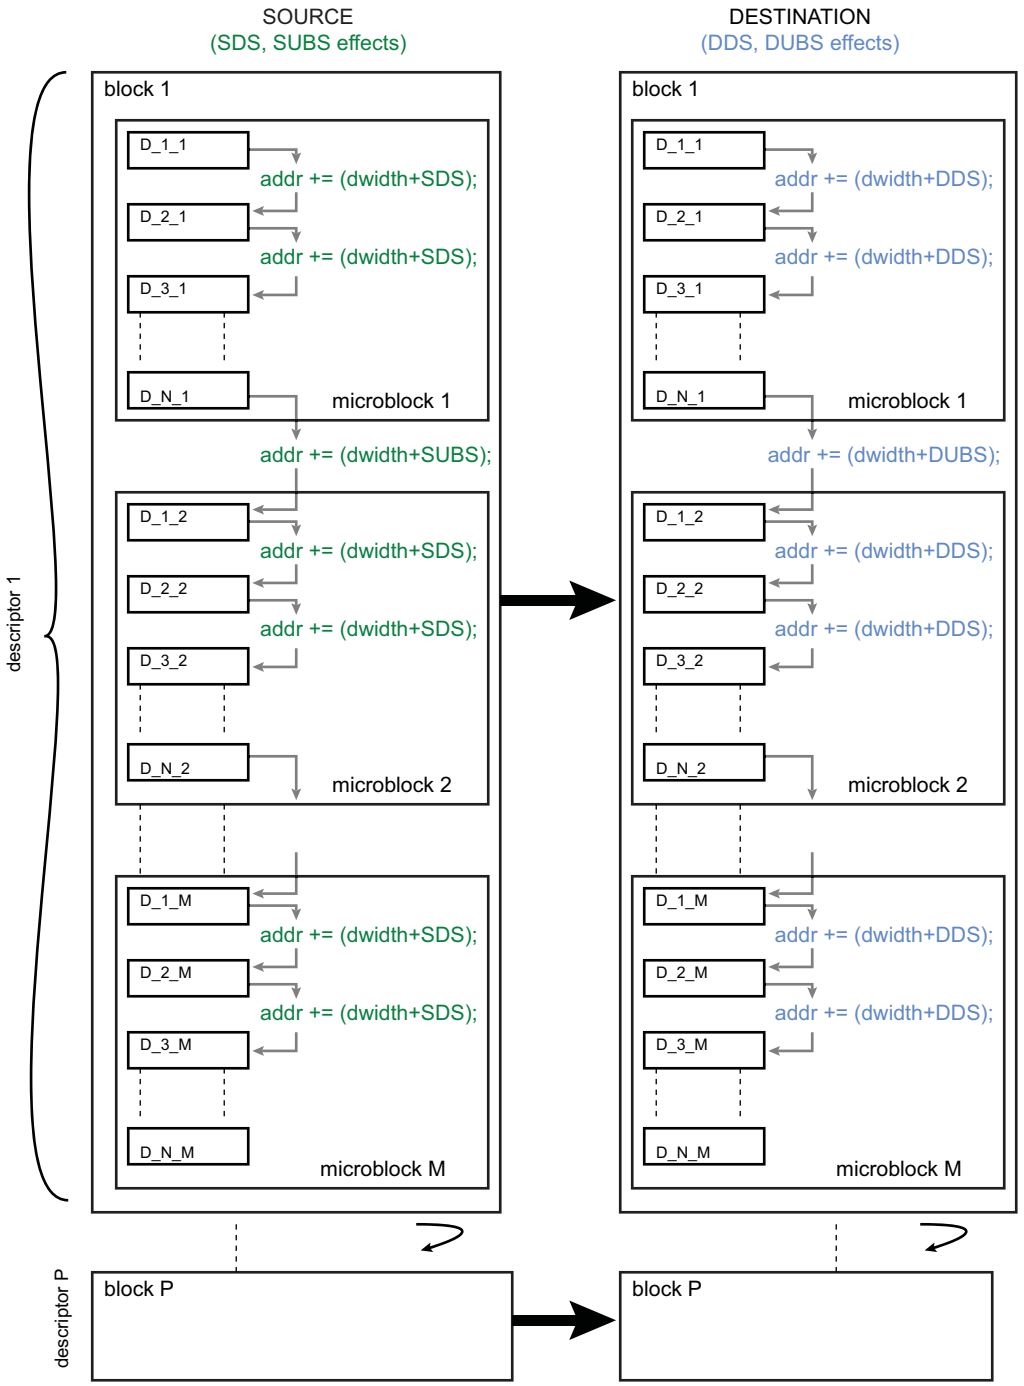
Stride: Number of address locations between successive elements/data measured in bytes.

Transfer Type: The transfer is hardware-synchronized when it is paced by the peripheral hardware request, otherwise the transfer is self-triggered (memory to memory transfer).

XDMAC Host Transfer: The host transfer is composed of a linked list of blocks. The channel address, control and configuration registers can be modified at the inter block boundary. The descriptor structure modifies the channel registers conditionally. Interrupts can be generated on a per block basis or when the end of linked list event occurs.

XDMAC Block: An XDMAC block is composed of a programmable number of microblocks. The channel configuration registers remain unchanged at the inter microblock boundary. The source and destination addresses are conditionally updated with a programmable signed number.

XDMAC Microblock: The microblock is composed of a programmable number of data. The channel configuration registers remain unchanged at the data boundary. The data address may be fixed (a FIFO location, a peripheral transmit or receive register), incrementing (a memory-mapped area) by a programmable signed number.



XDMAC Burst and Incomplete Burst: In order to improve the overall performance when accessing dynamic external memory, burst access is mandatory. Each data of the microblock is considered as a part of a memory burst. The programmable burst value indicates the largest memory burst allowed on a per channel basis. When the microblock length is not an integral multiple of the burst size, an incomplete burst is performed to read or write the last trailing bytes.

XDMAC Chunk and Incomplete Chunk: When a peripheral synchronized transfer is activated, the microblock splits into a number of data chunks. The chunk size is programmable. The larger the chunk is, the better the performance is. When the transfer size is not a multiple of the chunk size, the last chunk may be incomplete.

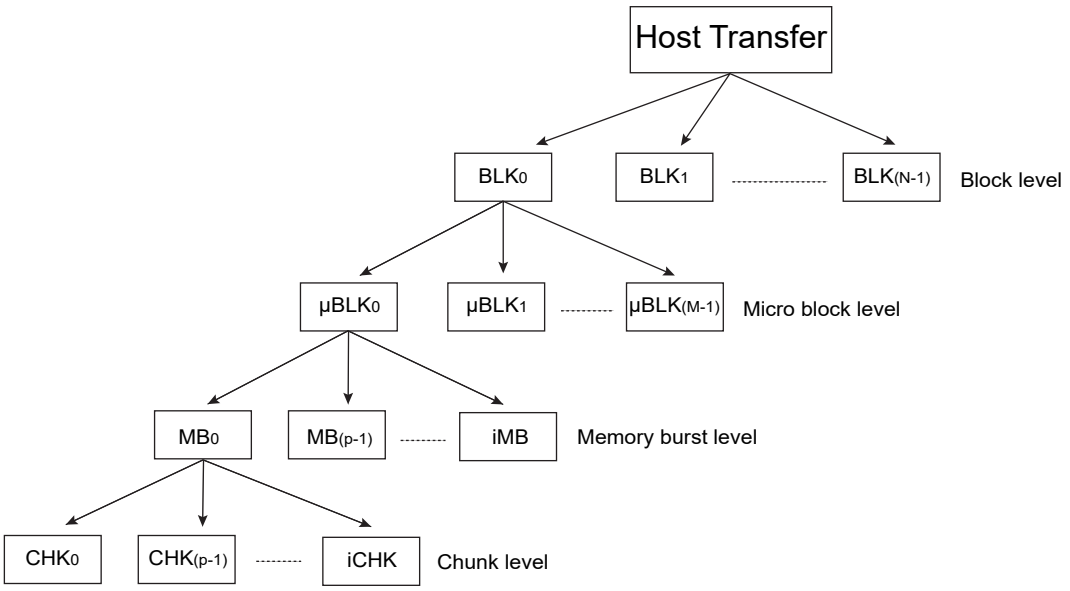
16.5.3. Transfer Hierarchy Diagrams

Figure 16.3. XDMAC Memory Transfer Hierarchy



16.5.4. Peripheral Synchronized Transfer

A peripheral hardware request interface is used to control the pace of the chunk transfer. When a peripheral is ready to transmit or receive a chunk of data, it asserts its request line and the DMA Controller transfers a data to or from the memory to the peripheral.

16.5.4.1. Peripheral to Memory Transfer

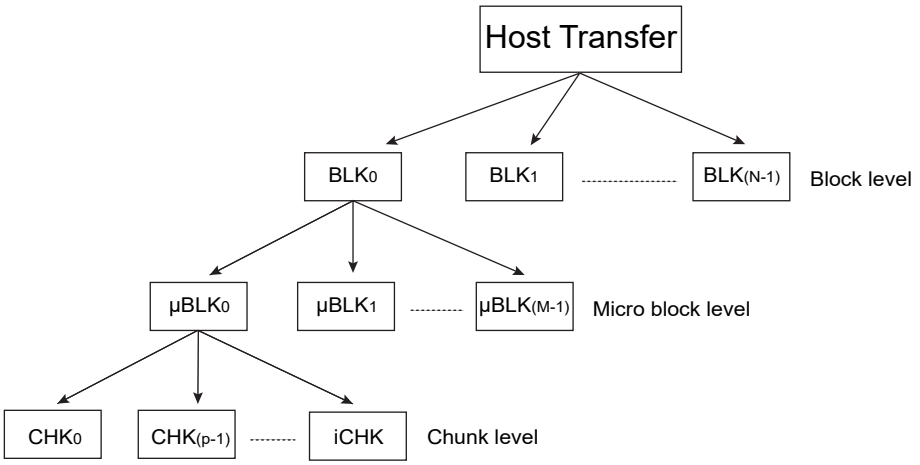
XDMAC reads data from the source peripheral and writes to the destination memory location.

Figure 16.4. Peripheral to Memory Transfer Hierarchy

It is a peripheral synchronized transfer, which means the memory transaction is synchronized with the hardware trigger that comes from the corresponding peripheral. It is also possible to use software trigger to initiate data transfer. Peripheral to memory transfer has a total of five levels of data transactions. They are Host, Block, Microblock, Burst, and Chunk level transactions. Host, Block, Microblock, and Burst level transactions work exactly the same way as explained earlier in

© 2026 Microchip Technology Inc. and its subsidiaries

the memory to memory data transfer section. In peripheral to memory data transfer, the burst level transaction is further split into chunk level data transaction to have higher granularity.



XDMAC Chunk and Incomplete Chunk: When a peripheral to memory transfer is activated, the burst level transaction is further split into a number of data chunks. The chunk size is configured in CSIZE field of XDMAC Channel Configuration Register (XDMAC_CCx). The chunk size denotes the number of 'data' to be transferred from the corresponding peripheral receive register to memory. In general, the chunk size is set as '1 data' in most of the peripherals (example: - UART, SPI, TWI, etc.), as the maximum size of their receive register is '1 data'. In specific scenarios, the chunk size is chosen more than 1 data. For example, the data receive/input registers of AES and HSMCI modules can hold more than '1 data'. So, the chunk size can be chosen as '2/4/8/16 data' accordingly. In this case, the larger the chunk size is, the better the performance is. When the amount of data chunks read becomes equal to the memory burst size, the actual data transaction starts (as a memory burst). During 'peripheral to memory' transfer, the data chunks are first read and stored into XDMAC's internal FIFO buffer. If their size becomes equal to the memory burst size, the FIFO buffer gets flushed out automatically, which makes 'memory burst transfer'. When the microblock size is not a multiple of the chunk size, the last chunk being transferred contains the last trailing data.

Note: If the chunk size is chosen as more than '1 data' for peripherals like UART, SPI, TWI, etc., XDMAC reads the same data register (receive/input register) multiple times. As a result, multiple copies of the same data are stored in the memory.

16.5.4.2. Memory to Peripheral Transfer

XDMAC reads data from the source memory location and writes to the destination peripheral.

Figure 16.5. Memory to Peripheral Transfer Hierarchy

Memory to Peripheral transfer is also a peripheral synchronized transfer. It has a total of four levels of data transactions. They are Host, Block, Microblock, and Chunk level transactions. Host, Block, and Microblock level transactions work exactly the same way as explained earlier in the memory to memory data transfer section. In memory to peripheral data transfer, the burst level transaction is not present. The microblock is directly split into a chunk level data transaction.

XDMAC Chunk and Incomplete Chunk: When a memory to peripheral transfer is activated, the microblock level transaction is directly split into a number of data chunks. The chunk size is configured in the CSIZE field of XDMAC Channel Configuration Register (XDMAC_CCx). The chunk size denotes the number of 'data' to be transferred from memory to the corresponding peripheral transmit register. In general, the chunk size is set as '1 data' in most of the peripherals (example: - UART, SPI, TWI, etc.), as the maximum size of their transmit register is '1 data'. In specific scenarios, the chunk size chosen is more than 1 data. For example, the data transmit/output registers of AES

© 2026 Microchip Technology Inc. and its subsidiaries

and HSMCI modules can hold more than '1 data'. So, the chunk size can be chosen as '2/4/8/16 data' accordingly. In this case, the larger the chunk size is, the better the performance. During 'memory to peripheral' transfer, the data chunks are immediately transferred when there is a hardware/ software trigger. Memory burst size doesn't play any role here. When the microblock size is not a multiple of the chunk size, the last chunk being transferred contains the last trailing data.

Note: In case the chunk size is chosen as more than '1 data' for peripherals like UART, SPI, TWI, etc., then XDMAC will overwrite the same data register (transmit/output register) with multiple data. As a result, only the last data gets transmitted.

16.5.4.3. Software Triggered Synchronized Transfer

The Peripheral hardware request can be software controlled using the SWREQ field of the XDMAC Global Channel Software Request Register (XDMAC_GSWR). The peripheral synchronized transfer is paced using a processor write access in the XDMAC_GSWR. Each bit of that register triggers a transfer request. The XDMAC Global Channel Software Request Status Register (XDMAC_GSWS) indicates the status of the request; when set, the request is still pending.

16.5.5. XDMAC Transfer Software Operation

Note: When performing a memory-to-memory transfer, configure the field XDMAC_CCx.PERID (where 'x' is the index of the channel used for the transfer) to 0x7F.

16.5.5.1. Single Block Transfer With Single Microblock

1. Read the XDMAC Global Channel Status Register (XDMAC_GS) to select a free channel.
2. Clear the pending Interrupt Status bit(s) by reading the selected XDMAC Channel x Interrupt Status Register (XDMAC_CISx).
3. Write the XDMAC Channel x Source Address Register (XDMAC_CSAx) for channel x.
4. Write the XDMAC Channel x Destination Address Register (XDMAC_CDAx) for channel x.
5. Program field UBLEN in the XDMAC Channel x Microblock Control Register (XDMAC_CUBCx) with the number of data.
6. Program the XDMAC Channel x Configuration Register (XDMAC_CCx):
   a. Clear XDMAC_CCx.TYPE for a memory-to-memory transfer, otherwise set this bit.
   b. Configure XDMAC_CCx.MBSIZE to the memory burst size used.
   c. Configure XDMAC_CCx.SAM and DAM to Memory Addressing mode.
   d. Configure XDMAC_CCx.DSYNC to select the peripheral transfer direction.
   e. Configure XDMAC_CCx.CSIZE to configure the channel chunk size (only relevant for peripheral synchronized transfer).
   f. Configure XDMAC_CCx.DWIDTH to configure the transfer data width.
   g. Configure XDMAC_CCx.SIF, XDMAC_CCx.DIF to configure the host interface used to read data and write data, respectively.
   h. Configure XDMAC_CCx.PERID to select the active hardware request line (only relevant for a peripheral synchronized transfer).
   i. Set XDMAC_CCx.SWREQ to use a software request (only relevant for a peripheral synchronized transfer).
7. Clear the following five registers:
   - XDMAC Channel x Next Descriptor Control Register (XDMAC_CNDCx)
   - XDMAC Channel x Block Control Register (XDMAC_CBCx)
   - XDMAC Channel x Data Stride Memory Set Pattern Register (XDMAC_CDS_MSPx)
   - XDMAC Channel x Source Microblock Stride Register (XDMAC_CSUSx)
   - XDMAC Channel x Destination Microblock Stride Register (XDMAC_CDUSx)

© 2026 Microchip Technology Inc. and its subsidiaries

This indicates that the linked list is disabled, there is only one block and striding is disabled.

8. Enable the Microblock interrupt by writing a '1' to bit BIE in the XDMAC Channel x Interrupt Enable Register (XDMAC_CIEx). Enable the Channel x Interrupt Enable bit by writing a '1' to bit IEx in the XDMAC Global Interrupt Enable Register (XDMAC_GIE).
9. Enable channel x by writing a '1' to bit ENx in the XDMAC Global Channel Enable Register (XDMAC_GE). XDMAC_GS.STx (XDMAC Channel x Status bit) is set by hardware.
10. Once completed, the DMA channel sets XDMAC_CISx.BIS (End of Block Interrupt Status bit) and generates an interrupt. XDMAC_GS.STx is cleared by hardware. The software can either wait for an interrupt or poll the channel status bit.

16.5.5.2.Single Block Transfer With Multiple Microblock

1. Read the XDMAC_GS register to choose a free channel.
2. Clear the pending Interrupt Status bit by reading the chosen XDMAC_CISx register.
3. Write the XDMAC_CSAx register for channel x.
4. Write the XDMAC_CDAx register for channel x.
5. Program XDMAC_CUBCx.UBLEN with the number of data.
6. Program XDMAC_CCx register (see "Single Block Transfer With Single Microblock").
7. Program XDMAC_CBCx.BLEN with the number of microblocks of data.
8. Clear the following registers:
   - XDMAC_CNDCx
   - XDMAC_CDS_MSPx
   - XDMAC_CSUSx XDMAC_CDUSx
     This indicates that the linked list is disabled and striding is disabled.
9. Enable the Block interrupt by writing a '1' to XDMAC_CIEx.BIE, enable the Channel x Interrupt Enable bit by writing a '1' to XDMAC_GIEx.IEx.
10. Enable channel x by writing a '1' to the XDMAC_GE.ENx. XDMAC_GS.STx is set by hardware.
11. Once completed, the DMA channel sets XDMAC_CISx.BIS (End of Block Interrupt Status bit) and generates an interrupt. XDMAC_GS.STx is cleared by hardware. The software can either wait for an interrupt or poll the channel status bit.

16.5.5.3.Host Transfer

1. Read the XDMAC_GS register to choose a free channel.
2. Clear the pending Interrupt Status bit by reading the chosen XDMAC_CISx register.
3. Build a linked list of transfer descriptors in memory. The descriptor view is programmable on a per descriptor basis. The linked list items structure must be word aligned. MBR_UBC.NDE must be configured to 0 in the last descriptor to terminate the list.
4. Configure field NDA in the XDMAC Channel x Next Descriptor Address Register (XDMAC_CNDAx) with the first descriptor address and bit XDMAC_CNDAx.NDAIF with the host interface identifier.
5. Configure the XDMAC_CNDCx register:
   a. Set XDMAC_CNDCx.NDE to enable the descriptor fetch.
   b. Set XDMAC_CNDCx.NDSUP to update the source address at the descriptor fetch time, otherwise clear this bit.
   c. Set XDMAC_CNDCx.NDDUP to update the destination address at the descriptor fetch time, otherwise clear this bit.
   d. Configure XDMAC_CNDCx.NDVIEW to define the length of the first descriptor.
6. Enable the End of Linked List interrupt by writing a '1' to XDMAC_CIEx.LIE.

© 2026 Microchip Technology Inc. and its subsidiaries

7. Enable channel x by writing a '1' to XDMAC_GE.ENx. XDMAC_GS.STx is set by hardware.
8. Once completed, the DMA channel sets XDMAC_CISx.BIS (End of Block Interrupt Status bit) and generates an interrupt. XDMAC_GS.STx is cleared by hardware. The software can either wait for an interrupt or poll the channel status bit.

16.5.5.4. Disabling A Channel Before Transfer Completion

Under normal operation, the software enables a channel by writing a '1' to XDMAC_GE.ENx, then the hardware disables a channel on transfer completion by clearing bit XDMAC_GS.STx. To disable a channel, write a '1' to bit XDMAC_GD.DIx and poll the XDMAC_GS register.

16.6. Linked List Descriptor Operation

16.6.1. Linked List Descriptor View

Bits 30:29 – QOS[1:0] Channel Quality of Service Level
This field indicates the current quality of service level for the channel. Refer to the section “Bus Matrix (MATRIX)”.

Bits 28:27 – NVIEW[1:0] Next Descriptor View

Value	Name	Description
0	NDV0	Next Descriptor View 0
1	NDV1	Next Descriptor View 1
2	NDV2	Next Descriptor View 2
3	NDV3	Next Descriptor View 3

Bit 26 – NDEN Next Descriptor Destination Update

Value	Description
0	Destination parameters remain unchanged.
1	Destination parameters are updated when the descriptor is retrieved.

Bit 25 – NSEN Next Descriptor Source Update

Value	Description
0	Source parameters remain unchanged.
1	Source parameters are updated when the descriptor is retrieved.

Bit 24 – NDE Next Descriptor Enable

Value	Description
0	Descriptor fetch is disabled.
1	Descriptor fetch is enabled.

Bits 23:0 – UBLEN[23:0] Microblock Length
This field indicates the number of data in the microblock. The microblock contains UBLEN data.

16.7. XDMAC Maintenance Software Operations

16.7.1. Disabling a Channel

A disable channel request occurs when a write operation is performed in the XDMAC_GD register. If the channel is source peripheral synchronized (bit XDMAC_CCx.TYPE is set and bit XDMAC_CCx.DSYNC is cleared), then pending bytes (bytes located in the FIFO) are written to memory and bit XDMAC_CISx.DIS is set. If the channel is not source peripheral synchronized, the current channel transaction (read or write) is terminated and XDMAC_CISx.DIS is set. XDMAC_GS.STx is cleared by hardware when the current transfer is completed. The channel is no longer active and can be reused.

16.7.2. Suspending a Channel

A disable channel request occurs when a write operation is performed in the XDMAC_GD register. If the channel is source peripheral synchronized (bit XDMAC_CCx.TYPE is set and bit XDMAC_CCx.DSYNC is cleared), then pending bytes (bytes located in the FIFO) are written to memory and bit XDMAC_CISx.DIS is set. If the channel is not source peripheral synchronized, the current channel transaction (read or write) is terminated and XDMAC_CISx.DIS is set. XDMAC_GS.STx is cleared by hardware when the current transfer is completed. The channel is no longer active and can be reused.

16.7.3. Flushing a Channel

A FIFO flush command is issued by writing to the XDMAC_SWF register. The content of the FIFO is written to memory. XDMAC_CISx.FIS (End of Flush Interrupt Status bit) is set when the last byte is successfully transferred to memory. The channel is not disabled. The flush operation is not blocking, meaning that read operation can be scheduled during the flush write operation. The flush operation is only relevant for peripheral to memory transfer where pending peripheral bytes are buffered into the channel FIFO.

16.7.4. Maintenance Operation Priority

16.7.4.1. Disable Operation Priority

- When a disable request occurs on a suspended channel, the XDMAC_GWS.WSx (Channel x Write Suspend bit) is cleared. If the transfer is source peripheral synchronized, the pending bytes are drained to memory. The bit XDMAC_CISx.DIS is set.
- When a disable request follows a flush request, if the flush last transaction is not yet scheduled, the flush request is discarded and the disable procedure is applied. Bit XDMAC_CISx.FIS is not set. Bit XDMAC_CISx.DIS is set when the disable request is completed. If the flush request transaction is already scheduled, the XDMAC_CISx.FIS is set. XDMAC_CISx.DIS is also set when the disable request is completed.

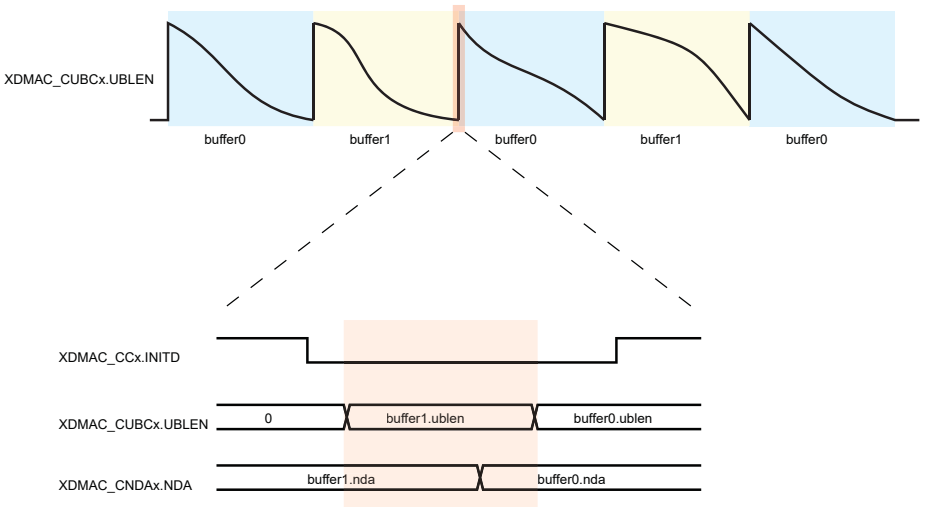
16.7.4.2. Flush Operation Priority

- When a flush request occurs on a suspended channel, if there are pending bytes in the FIFO, they are written out to memory, XDMAC_CISx.FIS is set. If the FIFO is empty, XDMAC_CISx.FIS is also set.
- If the flush operation is performed after a disable request, the flush command is ignored. XDMAC_CISx.FIS is not set.

16.7.4.3. Suspend Operation Priority

If the suspend operation is performed after a disable request, the write suspend operation is ignored.

© 2026 Microchip Technology Inc. and its subsidiaries



16.8. XDMAC Software Requirements

- Write operations to channel registers are not be performed in an active channel after the channel is enabled. If any channel parameters must be reprogrammed, this can only be done after disabling the XDMAC channel.
- XDMAC_CSAx and XDMAC_CDAx channel registers must be programmed with a byte, half-word or word aligned address depending on the Channel x Data Width field (DWIDTH) of the XDMAC Channel x Configuration Register. When a memory-to-peripheral transfer is performed, the XDMAC_CSAx address register has no alignment requirement.
- When a memory-to-memory transfer is performed, configure the field XDMAC_CCx.PERID (where 'x' is the index of the channel used for the transfer) to peripheral ID 127 (refer to the table "Peripheral Identifiers").
- When XDMAC_CC.INITD is set to 0, XDMAC_CUBC.UBLEN and XDMAC_CNDA.NDA field values are unreliable when the descriptor is being updated. The following procedure applies to get the buffer descriptor identifier and the residual bytes:

```
Read XDMAC_CNDAx.NDA(nda0)
Read XDMAC_CCx.INITD(initd0)
Read XDMAC_CCx.INITD(initd0)
Read XDMAC_CUBCx.UBLEN(ublen)
Read XDMAC_CCx.INITD(initd1)
Read XDMA_CNDAx.NDA(nda1)
If (nda0 == nda1 && initd0 == 1 && initd1 == 1).
Then the ublen is correct, the buffer id is nda.
Else retry
```

See the figure below.

					CGDISIF	CGDISFIFO	CGDISPIPE	CGDISREG
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit 8 – BXKBEN Boundary X Kilobyte Enable

Value	Description
0	XDMAC generates a non-sequential attribute on the system bus when address crosses the 1-Kilobyte boundary with a burst access.
1	XDMAC does not generate a non-sequential attribute on the system bus when address crosses the 1-Kilobyte boundary with a burst access.

Bit 3 – CGDISIF Bus Interface Clock Gating Disable

Value	Description
0	The automatic clock gating is enabled for the system bus interface.
1	The automatic clock gating is disabled for the system bus interface.

Bit 2 – CGDISFIFO FIFO Clock Gating Disable

Value	Description
0	The automatic clock gating is enabled for the main FIFO.
1	The automatic clock gating is disabled for the main FIFO.

Bit 1 – CGDISPIPE Pipeline Clock Gating Disable

Value	Description
0	The automatic clock gating is enabled for the main pipeline.
1	The automatic clock gating is disabled for the main pipeline.

Bit 0 – CGDISREG Configuration Registers Clock Gating Disable

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	The automatic clock gating is enabled for the configuration registers.
1	The automatic clock gating is disabled for the configuration registers.

© 2026 Microchip Technology Inc. and its subsidiaries

16.9.3. XDMAC Global Weighted Arbiter Configuration Register

Name: XDMAC_GWAC
Offset: 0x08
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 15:12 – PW3[3:0] Pool Weight 3
This field indicates the weight of pool 3 in the arbitration scheme of the DMA scheduler.

Bits 11:8 – PW2[3:0] Pool Weight 2
This field indicates the weight of pool 2 in the arbitration scheme of the DMA scheduler.

Bits 7:4 – PW1[3:0] Pool Weight 1
This field indicates the weight of pool 1 in the arbitration scheme of the DMA scheduler.

Bits 3:0 – PW0[3:0] Pool Weight 0
This field indicates the weight of pool 0 in the arbitration scheme of the DMA scheduler.

Bit 6 – ROIS Request Overflow Error Interrupt Status

Value	Description
0	Overflow condition has not occurred.
1	Overflow condition has occurred at least once. (This information is only relevant for peripheral synchronized transfers.)

Bit 5 – WBEIS Write Bus Error Interrupt Status

Value	Description
0	Write bus error condition has not occurred.
1	At least one bus error has been detected in a write access since the last read of the Status register.

Bit 4 – RBEIS Read Bus Error Interrupt Status

Value	Description
0	Read bus error condition has not occurred.
1	At least one bus error has been detected in a read access since the last read of the Status register.

Bit 3 – FIS End of Flush Interrupt Status

Value	Description
0	End of flush condition has not occurred.
1	End of flush condition has occurred since the last read of the Status register.

Bit 2 – DIS End of Disable Interrupt Status

Value	Description
0	End of disable condition has not occurred.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	End of disable condition has occurred since the last read of the Status register.

Bit 1 – LIS End of Linked List Interrupt Status

Value	Description
0	End of linked list condition has not occurred.
1	End of linked list condition has occurred since the last read of the Status register.

Bit 0 – BIS End of Block Interrupt Status

Value	Description
0	End of block interrupt has not occurred.
1	End of block interrupt has occurred since the last read of the Status register.

Reset	0	0		0		0	0	0

Bits 30:24 – PERID[6:0] Channel x Peripheral Hardware Request Line Identifier
This field contains the peripheral hardware request line identifier. PERID refers to identifiers defined in "DMA Controller Peripheral Connections".
Note: When a memory-to-memory transfer is performed, configure PERID to 0x7F.

Bit 23 – WRIP Write in Progress

Value	Name	Description
0	DONE	No active write transaction on the bus.
1	IN_PROGRESS	A write transaction is in progress.

Bit 22 – RDIP Read in Progress

Value	Name	Description
0	DONE	No active read transaction on the bus.
1	IN_PROGRESS	A read transaction is in progress.

Bit 21 – INITD Channel Initialization Done
When set to 0, XDMAC_CUBC.UBLEN and XDMAC_CNDA.NDA field values are unreliable each time a descriptor is being updated. See XDMAC Software Requirements.

Value	Name	Description
0	IN_PROGRESS	Channel initialization is in progress.
1	TERMINATED	Channel initialization is completed.

Bits 19:18 – DAM[1:0] Channel x Destination Addressing Mode

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
0	FIXED_AM	The address remains unchanged.
1	INCREMENTED_AM	The addressing mode is incremented (the increment size is set to the data size).
2	UBS_AM	The microblock stride is added at the microblock boundary.
3	UBS_DS_AM	The microblock stride is added at the microblock boundary; the data stride is added at the data boundary.

Bits 17:16 – SAM[1:0] Channel x Source Addressing Mode

Value	Name	Description
0	FIXED_AM	The address remains unchanged.
1	INCREMENTED_AM	The addressing mode is incremented (the increment size is set to the data size).
2	UBS_AM	The microblock stride is added at the microblock boundary.
3	UBS_DS_AM	The microblock stride is added at the microblock boundary, the data stride is added at the data boundary.

Bit 14 – DIF Channel x Destination Interface Identifier

Value	Name	Description
0	AHB_IF0	The data is written through system bus interface 0.
1	AHB_IF1	The data is written through system bus interface 1.

Bit 13 – SIF Channel x Source Interface Identifier

Value	Name	Description
0	AHB_IF0	The data is read through system bus interface 0.
1	AHB_IF1	The data is read through system bus interface 1.

Bits 12:11 – DWIDTH[1:0] Channel x Data Width

Value	Name	Description
0	BYTE	The data size is set to 8 bits
1	HALFWORD	The data size is set to 16 bits
2	WORD	The data size is set to 32 bits

Bits 10:8 – CSIZE[2:0] Channel x Chunk Size

Value	Name	Description
0	CHK_1	1 data transferred
1	CHK_2	2 data transferred
2	CHK_4	4 data transferred
3	CHK_8	8 data transferred
4	CHK_16	16 data transferred

Bit 7 – MEMSET Channel x Fill Block of Memory

Value	Name	Description
0	NORMAL_MODE	Memset is not activated.
1	HW_MODE	Sets the block of memory pointed by DA field to the specified value. This operation is performed on 8-, 16- or 32-bit basis.

Bit 6 – SWREQ Channel x Software Request Trigger

Value	Name	Description
0	HWR_CONNECTED	Hardware request line is connected to the peripheral request line.
1	SWR_CONNECTED	Software request is connected to the peripheral request line.

Bit 4 – DSYNC Channel x Synchronization

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
0	PER2MEM	Peripheral-to-memory transfer
1	MEM2PER	Memory-to-peripheral transfer

Bits 2:1 – MBSIZE[1:0] Channel x Memory Burst Size

Value	Name	Description
0	SINGLE	The memory burst size is set to one.
1	FOUR	The memory burst size is set to four.
2	EIGHT	The memory burst size is set to eight.
3	SIXTEEN	The memory burst size is set to sixteen.

Bit 0 – TYPE Channel x Transfer Type

Value	Name	Description
0	MEM_TRAN	Self-triggered mode (memory-to-memory transfer)
1	PER_TRAN	Synchronized mode (peripheral-to-memory or memory-to-peripheral transfer)

© 2026 Microchip Technology Inc. and its subsidiaries

16.9.29. XDMAC Channel x Data Stride Memory Set Pattern Register [x = 0..15]

Name: XDMAC_CDS_MSP
Offset: 0x7C + n*0x40 [n=0..15]
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	DDS_MSP[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	DDS_MSP[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8

	SDS_MSP[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:16 – DDS_MSP[15:0] Channel x Destination Data Stride or Memory Set Pattern
When XDMAC_CCx.MEMSET = 0, this field indicates the destination data stride.
Number of bytes for the data stride of channel x (two's complement). If the field is set to zero the data is contiguous (see Data Striding Diagram).
The DDS_MSP field is only relevant when XDMAC_CCx.SAM=UBS_DS_AM.
When XDMAC_CCx.MEMSET = 1, this field indicates the memory set pattern.

Bits 15:0 – SDS_MSP[15:0] Channel x Source Data Stride or Memory Set Pattern
When XDMAC_CCx.MEMSET = 0, this field indicates the source data stride.
Number of bytes for the data stride of channel x (two's complement). If the field is set to zero the data is contiguous (see Data Striding Diagram).
The SDS_MSP field is only relevant when XDMAC_CCx.SAM=UBS_DS_AM.
When XDMAC_CCx.MEMSET = 1, this field indicates the memory set pattern.

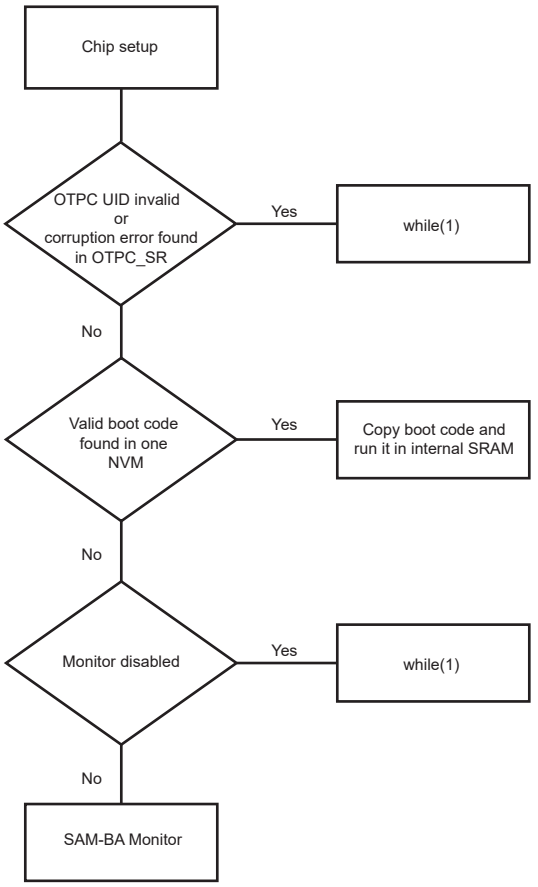
17. Boot Strategies

17.1. Standard Boot Strategy

17.1.1. Description

The chip always boots from the ROM memory at start-up or after a reset.

The ROM code is a boot program contained in the embedded ROM. It is also called “Bootloader”.



By default, the chip starts in Standard Boot mode. The user can choose to enable the Secure Boot mode. To know how to set up and configure the Secure Boot mode, see Secure Boot Strategy.

Note: JTAG access is disabled during the main part of the execution of the ROM code. It is re-enabled when the Standard SAM-BA® Monitor is executed or when jumping into a valid bootstrap.

17.1.2. Flow Diagram

The following figure shows the ROM code global flow.

Figure 17.1. ROM Code Flow Diagram

17.1.3. Chip Setup

When the chip is powered on, the system source clock is the Main RC oscillator. No external crystal or clock is needed during the external memories boot sequence.

The ROM code performs a low-level initialization that follows the steps described below:

1. PLLA initialization

© 2026 Microchip Technology Inc. and its subsidiaries

2. Main system bus clock selection: when the PLLA is stabilized, the main system bus clock source is switched from the main clock to the PLLA clock. The PMC Status register is polled to wait for MCK Ready.

Once the clock configuration is done, the ROM code initializes the ROM code console interface and sends a `RomBOOT` character string on it.

For clock frequencies, see Table 17.14.

Note: The ROM code only seeks an external clock source before launching the SAM-BA Monitor to get a more accurate clock signal for USB.

17.1.4. Boot Configuration

The boot sequence is controlled using a Boot Configuration Packet, stored in the OTP User area and accessed through the OTP Controller (OTPC).

17.1.4.1. Default Boot Sequence

When no Boot Configuration Packet is available in the OTP User area, the ROM code uses a default boot configuration and tries to boot from the following external memories:

- SD Card/e.MMC (SDMMC 0) - PA0 to PA5
- SD Card/e.MMC (SDMMC 1) - PA6 to PA11
- QSPI NOR Flash (QSPI) - PB15 to PB26
- NAND Flash (SMC) - PD0 to PD14
- SPI (FLEXCOM 5) - PA14 to PA17

See Table 17.15 for further details.

If no bootable file is found in any of these memories, the ROM code runs the SAM-BA Monitor.

17.1.4.2. Using a Boot Configuration Packet

Several boot configuration parameters can be customized by writing a Boot Configuration Packet in the OTP User area:

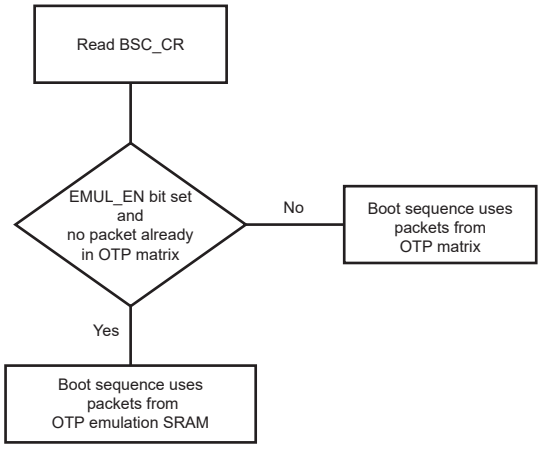
- IO configuration of boot memories (see Hardware and Software Constraints for a description of the IOs)
- Boot sequence
- UART port for the ROM code console
- Monitor disable

See Boot Configuration Packet for a detailed description of all the fields in this packet.

Out of factory, the OTP User area is empty and thus contains no Boot Configuration Packet.

OTP Emulation Mode

During a prototyping phase or for test purposes, it is possible to use the OTP Emulation mode. In this mode, the OTP matrix is replaced by an internal SRAM1. Once the Emulation mode is enabled, every OTP packet read and write is done in the internal SRAM1 instead of the OTP matrix. To instruct the ROM code to use this feature, set the bit EMUL_EN in the Boot Sequence Controller Configuration register (BSC_CR).



When using the emulated OTP, the user can test several boot configuration options, including the Secure Boot mode, without programming the OTP.

© 2026 Microchip Technology Inc. and its subsidiaries

Notes:

- The emulation SRAM is not backed up. After a power off/power on sequence, the configuration and content are lost.
- Once a packet is written in the OTP matrix, the OTP Emulation mode is no more available. Any instruction from the user to enable this mode in BSC_CR will fail, and packets will be read or written in the OTP memory.

Figure 17.2. Boot Configuration Loading

Bits 31:16 – WPKEY[15:0] Write Protect Key

Value	Name	Description
0x6683	PASSWD	Writing any other value in this field aborts the write operation of EMUL_EN. Always read as 0.

Bit 0 – EMUL_EN Request to use the OTP Emulation Mode for Boot Features

Value	Description
0	OTP Emulation mode is disabled.
1	The ROM code will use OTP Emulation mode for the boot features.

17.1.4.4.Boot Configuration Packet

Table 17.1. Boot Configuration Packet Structure

Offset	Name	Description
0x00	MON_DIS	Disables the SAM-BA Monitor
0x04	RESERVED	Reserved
0x08	CONSOLE_PIN	Defines the ROM code console pin muxing
0xC-0x44	MEM_CFGx[2]	Array of two 32-bit words used to set memory configurations for x=0..6 MEM_CFGx[0]: this word contains mandatory options for the connected external Flash memories. MEM_CFGx[1]: this word contains optional data specific to the memory described in word 0.

Access								
Reset								

Bits 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31 – DNU DO NOT USE

Bits 15:8 – WPKEY[7:0] Write Protect Key

Value	Name	Description
0x96	PASSWD	If any other value is written in this field, all other bit values are ignored.

Bit 7 – USE_CD Use a Card Detect pin

Value	Description
0	Use Card Detect disabled: the ROM code does not use any card detect pin and directly tries to boot from the memory connected to the SDMMC controller.
1	Use Card Detect enabled: the ROM code checks the state of the card detect pin. If the pin level is 0, the ROM code tries to boot from a memory connected to the SDMMC interface. If the pin level is 1, the ROM code skips the boot on SDMMC and jumps to the next interface in the boot sequence.

Bits 6:5 – PIO_ID[1:0] PIO Controller ID
ID of the PIO controller featuring the card detect pin.

Value	Description
0	PIOA
1	PIOB
2	PIOC
3	PIOD

Bits 4:0 – PIN[4:0] Card Detect Pin Index
Index of the card detect pin inside the PIO controller.

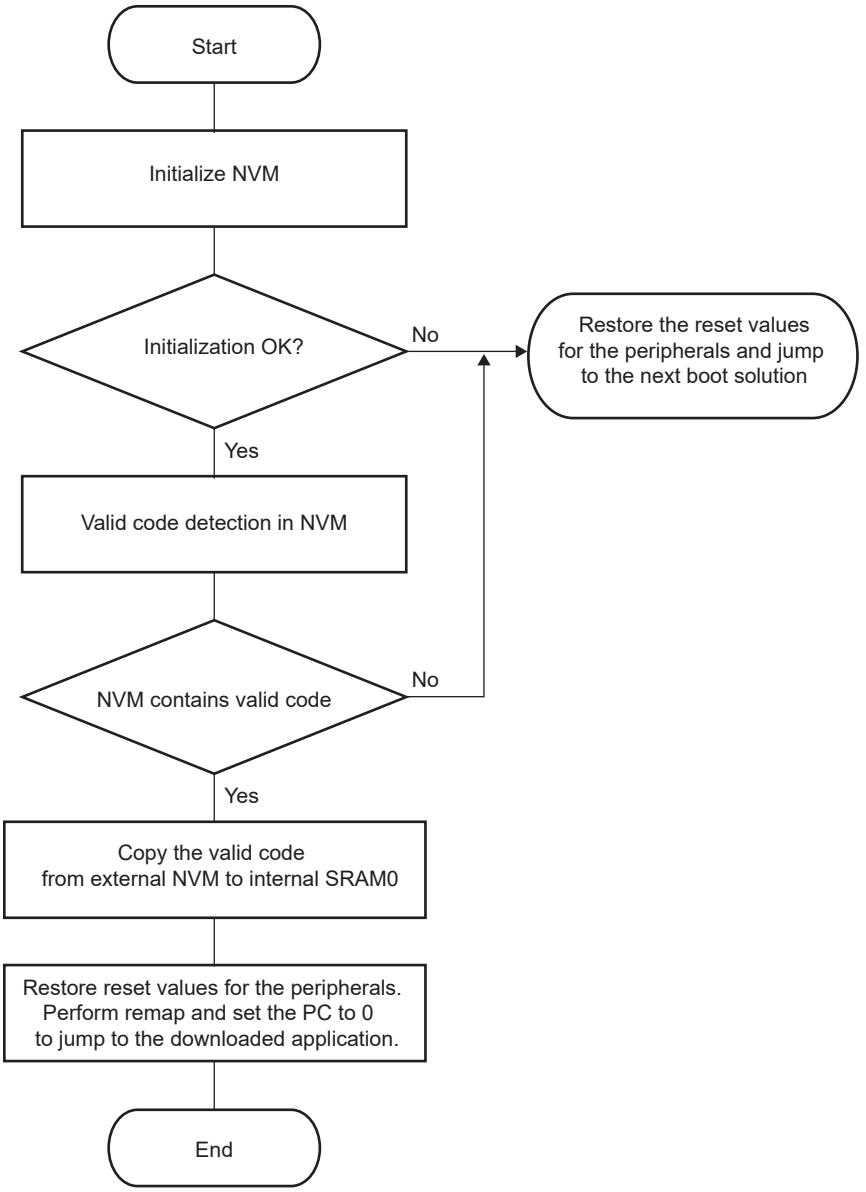
17.1.4.5.NVM Boot Sequence

For each memory listed in the default boot sequence or enabled in the Boot Configuration Packet, the ROM code performs the flash initialization and valid code detection as described below.



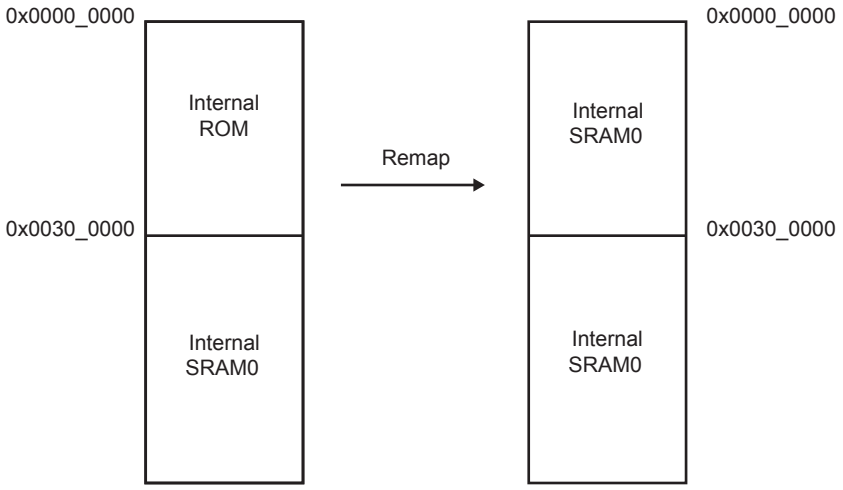
© 2026 Microchip Technology Inc. and its subsidiaries

Figure 17.3. NVM Bootloader Program

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 17.4. NVM Boot Diagram

The NVM bootloader program first initializes the PIOs related to the NVM device. Then it configures the right peripheral depending on the NVM and tries to access this memory. If the initialization fails, it restores the reset values for the PIO and the peripheral, and then tries to perform the same operations on the next NVM of the sequence.



If the initialization is successful, the NVM bootloader program reads the beginning of the NVM and determines if the NVM contains a valid code.

If the NVM does not contain a valid code, the NVM bootloader program restores the reset value for the peripherals and then tries to perform the same operations on the next NVM of the sequence.

If a valid code is found, this code is loaded from the NVM into the internal SRAM0 and executed by branching at address 0x0000_0000 after remap. This code may be the application code or a second-level bootloader. The code size must be lower than 32 KB.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 17.5. Remap Action after Download Completion

17.1.4.6.Valid Code Detection

Two types of valid code detection are available:

- Arm Exception Vectors Check
- boot.bin File Check

17.1.4.6.1.Arm Exception Vectors Check

The ROM code reads and analyzes the first 28 bytes corresponding to the first seven Arm exception vectors of the bootstrap.

These exception vectors must implement either a branch or a load with PC-relative addressing Arm instruction, except for the 6th vector.

More precisely, the ROM code must read either 0xEA or 0xE5 in bytes 3, 7, 11, 15 and 23.

The sixth vector (32 bits), at offset 0x14, must contain the size in bytes of the bootstrap to download from the external NVM into the internal SRAM.

The bootstrap size must not exceed the maximum bootstrap size allowed.

Example of valid vectors:

```
00              ea000006                    B 0x20
04              eafffffe                    B 0x04
08              eafffffe                    B 0x08
0c              eafffffe                    B 0x0c
10              eafffffe                    B 0x10
14              00008000                    ← Code size = 32 kbytes
18              eafffffe                    B 0x18
```

17.1.4.6.2.boot.bin File Check

This method is the one used on FAT-formatted SD card and e.MMC. The boot program must be a file named `boot.bin` written in the file system root directory. Its size must not exceed the maximum bootstrap size allowed.

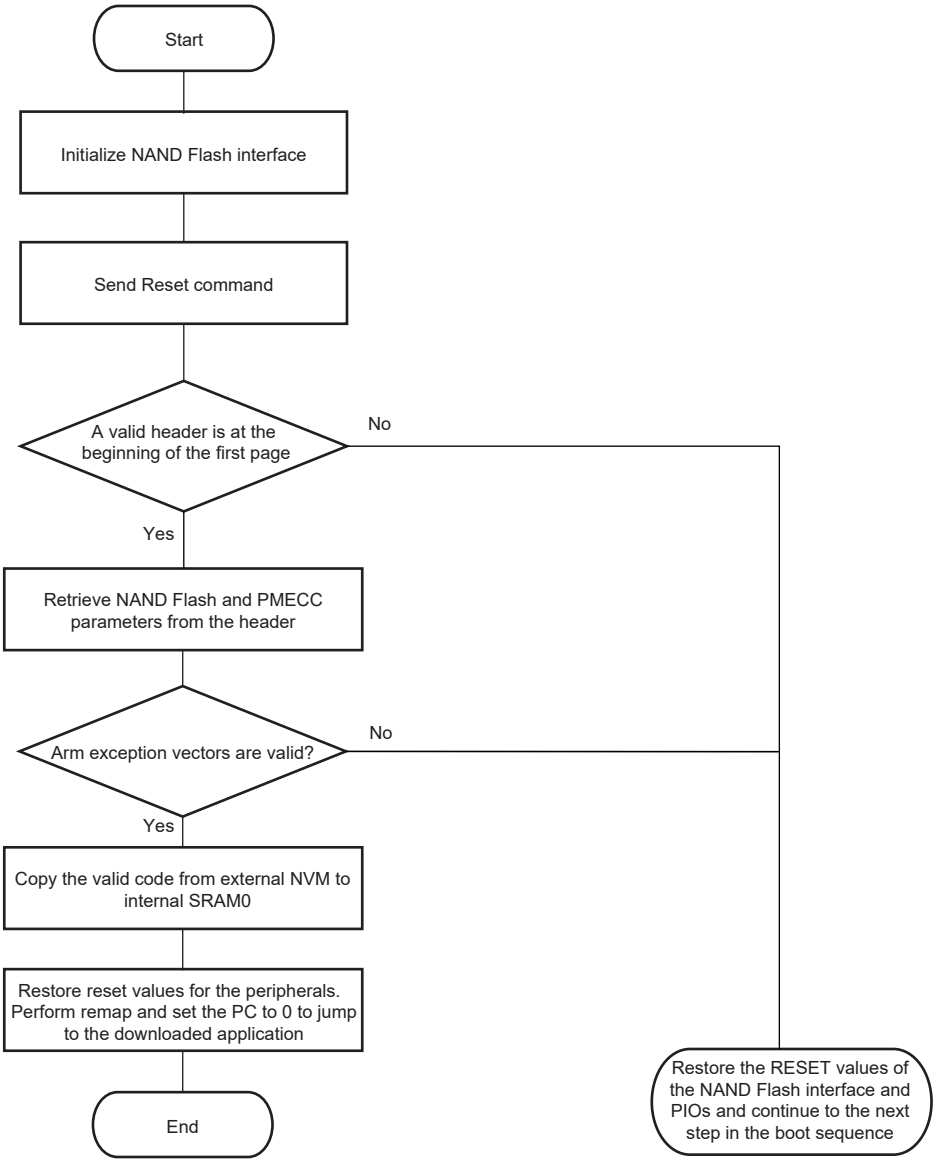
17.1.4.7.Detailed Memory Boot Procedures

17.1.4.7.1.NAND Flash Boot: NAND Flash Detection

After the NAND Flash interface configuration, a reset command is sent to the memory.

The reset time of the NAND memory, after this reset command, must not be higher than 100 µs.

© 2026 Microchip Technology Inc. and its subsidiaries



Hardware ECC detection and correction are provided by the PMECC peripheral. Refer to the section Functional Description in Programmable Multibit Error Correction Code Controller (PMECC) for more details.

The ROM code retrieves NAND Flash parameters and ECC requirements using a specific header store at the beginning of the bootstrap.

Once the ROM code has got the ECC parameters, it reads the first page again, with or without ECC, depending on the usePmecc parameter. Then it looks for a valid code programmed just after the header offset 0xD0. If the code is valid, the program is copied at the beginning of the internal SRAM.

Note: Booting on 16-bit NAND Flash is not possible; only 8-bit NAND Flash memories are supported.

Figure 17.6. Boot NAND Flash Download

© 2026 Microchip Technology Inc. and its subsidiaries

NAND Flash Specific Header Detection

After receiving the Initialization and Reset command, the ROM code reads the first page without an ECC check, to determine whether the NAND parameter header is present. The header is made of 52 times the same 32-bit word (for redundancy reasons) which must contain NAND and PMECC parameters used to correctly perform the read of the rest of the data in the NAND. This 32-bit word is described below.

If the header is valid, the Boot program continues with the detection of a valid code.

© 2026 Microchip Technology Inc. and its subsidiaries

Bits 31:28 – key[3:0] Value 0xC Must be Written here to Validate the Content of the Whole Word

Bits 26:18 – eccOffset[8:0] Offset of the First ECC Byte in the Spare Zone
A value below 2 is not allowed and is considered as 2.

Bits 17:16 – sectorSize[1:0] Size of the ECC Sector

Value	Description
0	For 512 bytes
1	For 1024 bytes per sector
Other values	For future use

Bits 15:13 – eccBitReq[2:0] Number of ECC Bits Required

Value	Description
0	2-bit ECC
1	4-bit ECC
2	8-bit ECC
3	12-bit ECC
4	24-bit ECC

Bits 12:4 – spareSize[8:0] Size of the Spare Zone in Bytes

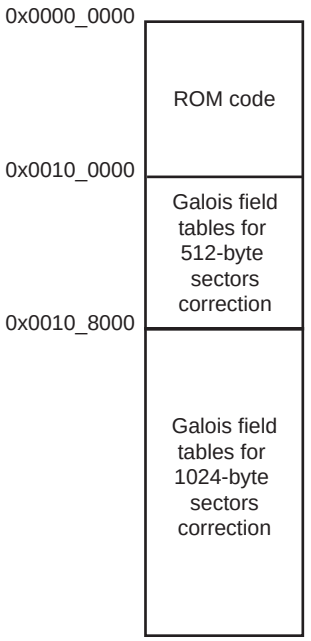
Bits 3:1 – nbSectorPerPage[2:0] Number of Sectors per Page

Value	Description
0	1 sector per page
1	2 sectors per page
2	4 sectors per page
3	8 sectors per page
4	16 sectors per page

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 0 – usePmecc Use PMECC

Value	Description
0	Do not use PMECC to detect and correct the data.
1	Use PMECC to detect and correct the data.



17.1.4.7.2.NAND Flash Boot: PMECC Error Detection and Correction

NAND Flash boot procedure uses PMECC to detect and correct errors during NAND Flash read operations

The ROM memory embeds the Galois field tables. The user does not need to embed or generate them in his/her own application.

The Galois field tables are mapped in the ROM just after the ROM code, as shown in the following figure.

Figure 17.7. Galois Field Table Mapping

17.1.4.8.SD Card/e.MMC Boot

When the Card Detect pin option is enabled in the Boot Configuration Packet, and if the level of the Card Detect pin is high (no card inserted), the ROM code will not try to initialize an SD card/e.MMC (no PIO will toggle). Otherwise, the SD card/e.MMC access is initiated (SDMMC interface PIO will toggle).

Supported SD Card Devices

SD Card Boot supports all SD card memories compliant with the SD Memory Card Specification V3.0. This includes SDMMC cards.

e.MMC with Boot Partition

The ROM code first checks if the e.MMC Boot Partition is enabled. If enabled, the ROM code reads the first “maximum bootstrap size” bytes of the boot partition, and copy them into the internal SRAM.

FAT Filesystem Boot

© 2026 Microchip Technology Inc. and its subsidiaries

If no boot partition is enabled on an e.MMC, the boot process continues with a standard SD card/ e.MMC detection, and the ROM code looks for a `boot.bin` file in the root directory of a FAT12/16/32 file system.

17.1.4.9.SPI Flash Boot

Two types of SPI Flash are supported: SPI Serial Flash and SPI DataFlash.

The ROM code tries to boot on SPI, first looking for SPI Serial Flash, and then for SPI DataFlash.

It uses the analysis of Arm exception vectors to detect a valid bootstrap code.

The SPI Flash read is done by means of a “Continuous Read” command from address 0x0. This command is 0xE8 for DataFlash devices and 0x0B for Serial Flash devices.

Supported DataFlash Devices

The ROM code supports the DataFlash devices listed in the following table.

Table 17.2. DataFlash Devices

Device	Density	Page Size (bytes)	Number of Pages
AT45DB011	1 Mbit	264	512
AT45DB021	2 Mbits	264	1024
AT45DB041	4 Mbits	264	2048
AT45DB081	8 Mbits	264	4096
AT45DB161	16 Mbits	528	4096
AT45DB321	32 Mbits	528	8192
AT45DB642	64 Mbits	1056	8192
AT45DB641	64 Mbits	264	37768

Supported Serial Flash Devices

The ROM code supports all SPI Serial Flash devices responding correctly to both “Get Status” and “Continuous Read” standard commands.

17.1.4.10.QSPI NOR Flash Boot

Hardware Considerations

The ROM code configures the hardware so that:

- the QSPI controller uses SPI Mode 0 (CPOL = 0 and CPHA = 0),
- the QSPIx_SCK clock frequency is ≤ 50 MHz,
- QSPIx_SCK and QSPIx_CS do not use any internal pull-up/pull-down resistor,
- each QSPIx_IO{0,1,2,3} uses the PIO controller’s internal pull-up resistor.

Software Considerations

Before reading any data, the ROM code sends a software reset to the QSPI NOR memory. Then the ROM code looks for the Serial Flash Discoverable Parameters (SFDP) of the QSPI NOR memory, if available, to learn the parameters (instruction op code, timing settings) required to read the user-programmed boot file.

If SFDP tables are not available, the ROM code uses hard-coded values as fallback settings to read the boot file.

The ROM code supports any QSPI NOR memory which can provide its Serial Flash Discoverable Parameters (SFDP) as defined in the JEDEC® JESD216B standard.

The supported revisions of this JEDEC standard are:

- JESD216 (version 1.0)

© 2026 Microchip Technology Inc. and its subsidiaries

- JESD216 rev. A (version 1.5)
- JESD216 rev. B (version 1.6)

Refer to the QSPI NOR memory data sheet to check compliance with any of the above JEDEC JESD216 standard revisions/versions.

QSPI NOR Memories with SFDP (JEDEC JESD216x Compliant)

The ROM code reads the memory SFDP tables to learn the factory settings (instruction op code, number of dummy cycles, etc.). The ROM code also reads bits[22:20] in DWORD15 from the Basic Flash Parameter table (refer to the JEDEC JESD216B specification) to select and then execute the relevant procedure, if any, to set the Quad Enable (QE) bit in some internal register of the QSPI NOR memory.

For most memory manufacturers, this QE bit is non-volatile and must be set before performing any Quad SPI command. This is the only persistent setting that the ROM code may change in the internal registers of the QSPI NOR memory. All other settings are kept unchanged.

Refer to the QSPI NOR memory data sheet to find which value was chosen by the memory manufacturer and written into the SFDP tables.

Finally, the ROM code reads the boot file from the data area of the QSPI NOR memory, and then continues its boot procedure.

QSPI NOR Memories without SFDP

This section only applies when the ROM code fails to read the SFDP tables from the QSPI NOR memory.

The ROM code reads the JEDEC ID of the QSPI NOR memory, and then selects the read settings based on the manufacturer ID (first byte of the JEDEC ID) from the following hard-coded values:

Table 17.3. QSPI NOR Memories Settings

	Cypress (01h)	Micron (20h)	Macronix (C2h)	Winbond (EFh)	Others
Fast Read protocol	SPI 1-4-4	SPI 1-4-4	SPI 1-4-4	SPI 1-4-4	SPI 1-1-1
Fast Read op code	EBh	EBh	EBh	EBh	0Bh
Address width	24 bits	24 bits	24 bits	24 bits	24 bits
Number of mode clock cycles	2	1	2	2	0
Number of wait states	4	9	4	4	8
Value of mode cycles to enter the 0-4-4 mode (XIP)	A0h	0h The ROM code first sets SIP bit[3] in the Volatile Configuration register (VCR)	0Fh	A5h	N/A
Value of mode cycles to exit the 0-4-4 mode (normal read)	00h	1h	00h	FFh	N/A
XIP supported	Yes	Yes	Yes	Yes	No

Those hard-coded parameters give a last chance to the ROM code to boot from a QSPI NOR memory in either Normal mode or XIP (Continuous Read) mode.

Table 17.4. QSPI NOR Memories Tested with and Supported by ROM Code (Non Exhaustive)

Manufacturer	Memories
Microchip (SST)	SST26VF016B SST26VF032B SST26VF032BA SST26VF064B

Winbond	W25M512

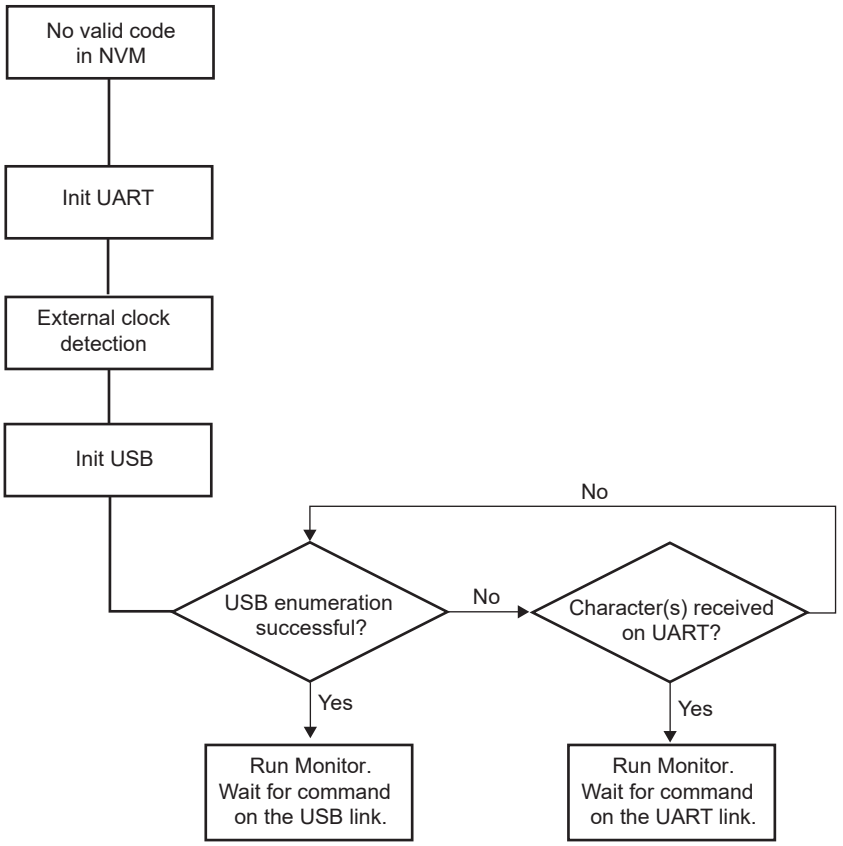
Note: For an updated list of memories, refer to the "Booting from External Non-Volatile Memory (NVM) on SAM9X7 Series MPUs" (AN4971) application note, available on www.microchip.com.

17.1.5. SAM-BA Monitor

This part of the ROM code is executed when no valid bootstrap is found in an external NVM during the boot sequence, and if the Monitor is not disabled in the Boot Configuration Packet.

The SAM-BA Monitor enables a serial communication link over either the USB Device peripheral or the ROM code console interface. It offers a set of simple commands to communicate with the chip using only a serial link controlled by an external device.

During the whole boot sequence, the Main RC oscillator is used as the main clock of the system. However, to use the USB Device interface, an accurate external clock must be supplied. Thus, before running the SAM-BA Monitor, the ROM code checks whether such an external clock is available. If a valid external clock or crystal is found, the UPLL is configured to allow communication on the USB Device link; otherwise, the USB Device interface is not activated and only the ROM code console is used for the SAM-BA Monitor.



SAM-BA Monitor steps:

- Initialize the ROM code console interface
- Initialize the USB Device interface (if a valid external clock is available)
- Enter a loop waiting for
  - the USB device enumeration by an external host, or
  - a character reception on the ROM code console interface

Once the communication interface is identified, the application runs in an infinite loop waiting for different commands as listed in Table 17.5.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 17.8. SAM-BA Monitor

17.1.5.1.Command List

Table 17.5. SAM-BA Monitor Commands

Command	Action	Argument(s)	Example
N	Set Normal mode	No argument	**N**#
T	Set Terminal mode	No argument	**T**#
O	Write a byte	Address, Value#	**O**200001,CA#
o	Read a byte	Address,#	**o**200001,#
H	Write a halfword	Address, Value#	**H**200002,CAFE#
h	Read a halfword	Address,#	**h**200002,#
W	Write a word	Address, Value#	**W**200000,CAFEDECA#
w	Read a word	Address,#	**w**200000,#
S	Send a file	Address,NbOfBytes#	**S**200000,1234#
R	Receive a file	Address, NbOfBytes#	**R**200000,1234#
G	Go	Address#	**G**200200#
V	Display version	No argument	**V**#

- Mode commands:
  - Normal mode configures the SAM-BA Monitor to send/receive data in binary format.
  - Terminal mode configures the SAM-BA Monitor to send/receive data in ASCII format.
- Write commands: Writes a byte (**O**), a halfword (**H**) or a word (**W**) to the target.
  - Address: address in hexadecimal

© 2026 Microchip Technology Inc. and its subsidiaries

  - Value: byte, halfword or word to write in hexadecimal
  - Output: '>'
- Read commands: Reads a byte (**o**), a halfword (**h**) or a word (**w**) from the target.
  - Address: address in hexadecimal
  - Output: the byte, halfword or word read in hexadecimal followed by '>'
- Send a file (**S**): The host will send a buffer of data to be stored at a specified address in the device
  - Address: address in hexadecimal
  - NbOfBytes: number of bytes (in hexadecimal format) to be received from the host
  - Output: '>'
    Note: A timeout on this command is reached when the prompt '>' appears before the end of the command execution.
- Receive a file (**R**): The host requests to read a buffer of data from a specified address in the device.
  - Address: address in hexadecimal
  - NbOfBytes: number of bytes (in hexadecimal format) to be sent to the host
  - Output: '>'
- Go (**G**): Jumps to a specified address and executes the code.
  - Address: address to jump to in hexadecimal
  - Output: '>' once returned from the program execution. If the executed program does not manage the link register and does not return, the prompt is not displayed.
- Get ROM code version (**V**): Returns the ROM code version.
  - Output: version, date and time of ROM code followed by '>'

17.1.5.2.ROM Code Console Interface

The ROM code console interface (DBGU or UART) can be configured in the Boot Configuration Packet.

At the beginning of ROM code execution, the `RomBOOT` character string is sent on this same console interface.

Communication settings:

- 115200 bauds
- 8 bits of data
- No parity
- 1 stop bit

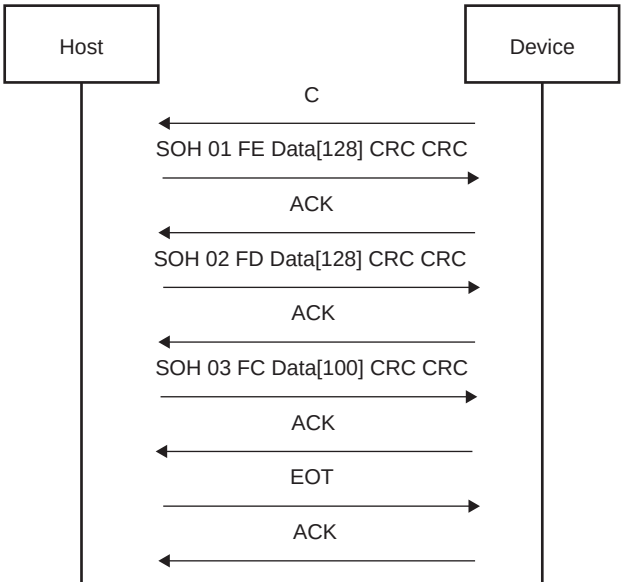
17.1.5.2.1.Xmodem Protocol

The "Send File" and "Receive File" commands use the Xmodem protocol. Any terminal using this protocol can be used to send data buffers to this device. The size of the binary file to send depends on the SRAM size embedded in the product. In all cases, the size of the binary file must be lower than the SRAM size because the Xmodem protocol requires some SRAM memory in order to work.

The Xmodem protocol supported is the 128-byte length block. This protocol uses a two-character CRC16 to guarantee detection of maximum bit errors.

Xmodem protocol with CRC is supported by successful transmission reports provided both by a sender and by a receiver. Each transfer block is as follows:

<SOH><blk #><255-blk #><--128 data bytes--><checksum> in which:



- <SOH> = 01 hex

© 2026 Microchip Technology Inc. and its subsidiaries

- <blk #> = binary number, starts at 01, increments by 1, and wraps 0FFH to 00H (not to 01)
- <255-blk #> = 1's complement of the blk#.
- <checksum> = 2-byte CRC16

The following figure shows a transmission using this protocol.

Figure 17.9. Xmodem transfer example

17.1.5.3.USB Device Interface

17.1.5.3.1.Supported External Crystal or External Clocks

The SAM-BA Monitor requires an accurate external clock or crystal to use a USB connection. In other cases, only a UART connection is available for the SAM-BA Monitor feature.

17.1.5.3.2.USB Class

The device uses the USB Communication Device Class (CDC) drivers to take advantage of the installed PC Serial Communication software to talk over the USB. The CDC is supported by Linux, macOS®, and Microsoft Windows®. The CDC document, available at www.usb.org, describes how to implement devices such as ISDN modems and virtual COM ports.

The vendor ID is 0x03EB. The product ID is 0x6124. These references are used by the host operating system to mount the correct driver. On Windows systems, INF files contain the correspondence between vendor ID and product ID.

17.1.5.3.3.Enumeration Process

The USB protocol is a host/client protocol. The host starts the enumeration, sending requests to the device through the control endpoint. The device handles standard requests as defined in the USB specification.

Table 17.6. Handled Standard Requests

Request	Definition
GET_DESCRIPTOR	Returns the current device configuration value
SET_ADDRESS	Sets the device address for all future device accesses
SET_CONFIGURATION	Sets the device configuration
GET_CONFIGURATION	Returns the current device configuration value
GET_STATUS	Returns status for the specified recipient

© 2026 Microchip Technology Inc. and its subsidiaries

Table 17.6. Handled Standard Requests (continued)

Request	Definition
SET_FEATURE	Used to set or enable a specific feature
CLEAR_FEATURE	Used to clear or disable a specific feature

The device also handles some class requests defined in the CDC class.

Table 17.7. Handled Class Requests

Request	Definition
SET_LINE_CODING	Configures DTE rate, stop bits, parity and number of character bits
GET_LINE_CODING	Requests current DTE rate, stop bits, parity and number of character bits
SET_CONTROL_LINE_STATE	RS-232 signal used to indicate to the DCE device that the DTE device is now present

Unhandled requests are stalled.

17.1.5.3.4.Communication Endpoints

Endpoint 0 is used for the enumeration process.

Endpoint 1 (64-byte Bulk OUT) and endpoint 2 (64-byte Bulk IN) are used as communication endpoints.

SAM-BA Monitor commands are sent by the host through Endpoint 1. If required, the message is split into several data payloads by the host driver.

If the command requires a response, the host sends IN transactions to pick up the response.

17.2. Secure Boot Strategy

17.2.1. Description

The Secure Boot mode authenticates and deciphers a boot file stored in an external Non-Volatile Memory (NVM) prior to its execution. The boot file can be a bootstrap code or the user application. The secure boot ensures that only authorized code is executed, thus protecting the customer IP and providing a Root of Trust (RoT) in the hardware.

When the Secure Boot mode is enabled, the chip only allows booting on an authenticated and ciphered boot file. The boot file can be authenticated and deciphered in two ways:

- AES-CBC-CMAC mode:
  - Authentication is performed using the customer private CMAC key stored in the OTP memory and the AES-CMAC algorithm.
  - Boot file decryption is performed using the customer private CBC key stored in the OTP memory and the AES-CBC algorithm.
- AES-CBC-RSA mode:
  - Authentication is performed using the customer public key contained in the last X.509 certificate chain stored after the boot file.
  - Boot file decryption is performed using the customer private CBC key stored in the OTP memory and the AES-CBC algorithm.

Encryption is supported by an AES (using HW acceleration); in addition, either symmetric (AES-CMAC) or asymmetric (RSA-based using an X.509 certificate chain) authentication is supported.

17.2.2. Secure Boot Configuration

In addition to the Boot Configuration Packet content, the secure part of the boot sequence flow is controlled with data stored in the Secure Boot Configuration Packet.

The Secure Boot Configuration, stored in the Secure Boot Configuration Packet in the OTP user area, contains all the information required to boot in Secure mode:

© 2026 Microchip Technology Inc. and its subsidiaries

- Secure Boot mode enable
- Authentication mode (AES-CMAC or RSA)
- Address of the regular packet containing the customer key wrapped with the PUF key

See Secure Boot Configuration Packet for a detailed description of the fields in the Secure Boot Configuration Packet.

During the prototyping phase, the OTPC Emulation mode can be used to test several configurations and the Secure Boot Mode without burning real OTP bits in the OTP matrix. See Boot Configuration Packet for more details.

17.2.3. Secure Boot Configuration Packet

Table 17.8. Secure Boot Configuration Packet Content

Offset	Name	Description
0x00	SEC_MODE_EN	Secure Boot mode enabled
0x04	AUTH_MODE	Authentication mode selection
0x08	DNU	Do Not Use (keep 0x0 value)
0x0C	KEY_WRITTEN	Key written
0x10	IV	AES Initialization Vector packet address
0x14	RSA_HASH	RSA root certificate public key hash packet address
0x18	CBC_KEY	AES CBC key packet address
0x1C	CMAC_KEY	AES CMAC key packet address

17.2.4. Valid Code Detection in Secure Boot Mode

The valid code detection in Secure Boot mode is similar to the one in Standard Boot mode. However, additional checks and operations are performed.

If the initialization of NVM is successful, the ROM code reads and deciphers the first 32 bytes of the potential secure boot file to find a valid Arm exception vector table (see Arm Exception Vectors Check). From the sixth vector, the ROM code extracts the size of the boot file including its signature. When the AUTH_MODE field is set to 1 in the Secure Boot Configuration Packet, the size of the X.509 certificate chain is also extracted. The boot file size must be 16 bytes aligned (AES block size). The sum of the boot file size and the certificate chain size must be lower than the maximum bootstrap size. If these first validations fail, the ROM code restores the memory interface PIO and its settings to their reset values and then tries to boot on the next NVM in the boot sequence.

Otherwise, the total size is used to copy the boot file, its signature and the X.509 certificate chain from the NVM into the internal SRAM.

Next, depending on the AUTH_MODE field in the Secure Boot Configuration Packet, either the AES-CMAC digest or the RSA signature of the boot file is checked. As usual, if this final validation fails, the peripheral is reset and the ROM code jumps to the next NVM in the boot sequence.

If the boot file verification passes, the ROM code deciphers the boot file stored in the internal SRAM0.

Since the NVM interface is no longer needed, the ROM code restores the memory interface PIO and its settings to their reset values.

Finally, the ROM code locks access to the ROM area, enables JTAG and then branches to the beginning of the internal SRAM0 to execute the deciphered bootstrap.

© 2026 Microchip Technology Inc. and its subsidiaries

17.2.4.1.6th Vector Format

When the AUTH_MODE field is cleared in the Secure Boot Configuration Packet, the sixth entry of the Arm exception vector table stores the size of the boot file in bytes, including the 16 bytes of its AES-CMAC signature.

When the AUTH_MODE field is set to 1 in the Boot Configuration word, the sixth entry of the Arm exception vector table stores both the size of the boot file including its RSA signature and the size of the X.509 certificate chain. The size of the RSA signature is also encoded.

Bit	31	30	29	28	27	26	25	24
	CERTIFICATE_SIZE							
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**

Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
	BT_SIZE							
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	BT_SIZE							

BT_SIZE: Boot file size, in bytes

SIG_CODE: Code for the RSA signature length

00: 2048 bits

01: 3072 bits

10: 4096 bits

11: RFU

CERTIFICATE_SIZE: Size of the of X.509 certificate chain, in bytes

© 2026 Microchip Technology Inc. and its subsidiaries

17.2.4.2.e.MMC/SD Card File System

In Secure Boot mode, the ROM code looks for a `boot.cip` file in the root directory of a FAT12/16/32 file system. The `boot.cip` file must contain the ciphered bootstrap, its signature and the chain of X.509 certificates, in this order.

17.2.5. Encryption, Decryption and Authentication

All customer secret keys are stored securely (wrapped using the PUF feature) in a regular packet. The customer's AES Initialization Vector read from the OTP User area and the first key are used by the AES-CBC algorithm, whereas the second is dedicated to the AES-CMAC computation.

Encryption and decryption are processed using the NIST-recommended AES-CBC mode defined in NIST Special Publication 800-38A [NIST_MODE_OP].

When selected, the Message Authentication Code is processed using the NIST-recommended CMAC. The CMAC used as a Message Authentication Code (MAC) is the CMAC based on the AES. The AES-CMAC outputs a 128-bit digest.

Otherwise, the authentication is secured by an RSA signature. The public key cryptographic implementation then relies on X.509 certificates. These certificates are chained and stored right after the boot file and its signature in the NVM.

The first certificate in the chain (at the lowest address in memory) is called the "root certificate". The modulus and the exponent are extracted from the public key stored in the root certificate. A SHA-256 digest is computed on the concatenation of the modulus and the exponent. This 256-bit digest is compared to the "RSA hash" to validate the root certificate.

Then, except for the root certificate, every certificate is signed by the private key associated with the previous certificate in the chain. So, its previous certificate is used to validate a certificate in a recursive process.

Finally, the boot file is signed with the private key associated with the last certificate. So, the last certificate is used to validate the boot file signature.

17.2.6. Secure Monitor

When no bootable program is found in any external NVM memory during the boot sequence and Secure Boot mode is enabled, the ROM code executes the Secure Monitor.

The set of commands implemented in the Secure Monitor enables the user to send commands to configure the Secure Boot mode, to write the customer key and the RSA root certificate public key hash, and to execute secure applets.

17.2.6.1.Generic Commands

The command format is composed of an opcode and arguments, and ends with a '#' character. Depending on the command, a data payload can be added after the command. In this case, the payload must be sent after the Secure Monitor has acknowledged the command and instructed how the data payload must be split (size of the payload).

17.2.6.2.Command Format

The commands are formatted as follows:

____,_____,_____,_____,__#

```
opcode addr length not_used rw
```

where:

- `opcode`—4 characters of the command.
- `addr`—the address field is max 8 characters long, and contains the hexadecimal address value without '0x'.

© 2026 Microchip Technology Inc. and its subsidiaries

- `length`—in case of a write command, this field indicates the size of the data to be sent, in hexadecimal format without '0x'.
- `not_used`—this field is not used for the moment.
- `rw`—indicates a read or write operation (00 for read, 01 for write).

Table 17.9. Read Version Command

Command	Description
RVER	Read ROM code version

Table 17.10. Key Management Commands

Command	Description
WCKY	Send customer keys and initialization vector (640 bits) for AES-CMAC
WCKP	Send customer key and RSA hash of root certificate public key for AES-RSA mode

Table 17.11. Applet-Related Commands

Command	Description
SAPT	Send applet
SMBX	Send applet mailbox content
RMBX	Read applet mailbox content
EAPP	Execute applet
SFIL	Send file to an already loaded applet
RFIL	Read file from the buffer filled by an applet after its execution

17.2.6.3.Monitor Answer

The Secure SAM-BA Monitor answers any command with an acknowledgment message formatted as follows:

____,_____,_____#[<payload>]

```
opcode errcode length
```

where:

- `opcode`—4 characters of the command
- `errcode`—value of the error code
- `length`—in cases where the Monitor must send data to SAM-BA, this field shows how much data is in the payload, thus how much data SAM-BA has to read.
- `payload`—optional data, depends on the command.

Table 17.12. Command List

Command	Full Name	Description
CACK	SEND_CMD_ACK	Returns the status of simple commands
ASTA	SEND_APPLET_STATUS	Returns the status after execution of an applet
SVER	SEND_ROM_VERSION	Returns the ROM code version

Table 17.13. Error Code

Error Name	Hex Value	Description
secCmdOK	0x000000000	Command OK
secCmdTooLong	0xFFFFFFFF	Whole command size too long
secCmdOpcodeSizeErr	0xFFFFFFFE	Opcode size too long
secCmdAddrSizeErr	0xFFFFFFFD	Address field size too long
secCmdLenSizeErr	0xFFFFFFFC	Length field size too long

© 2026 Microchip Technology Inc. and its subsidiaries

Table 17.13. Error Code (continued)

Error Name	Hex Value	Description
secCmdRWSizeErr	0xFFFFFFFA	RW field size too long
secCmdOpcodeUnknown	0xFFFFFFF9	Unknown command op-code
secCmdCustKeyLengthErr	0xFFFFFFF8	Customer key payload message size error
secCmdCustKeyNotWritten	0xFFFFFFF7	Customer key not written in OTP
secCmdCustKeyAlreadyWritten	0xFFFFFFF6	Customer key already written in OTP
secCmdCmacErr	0xFFFFFFF5	Message CMAC error
secCmdDecryptErr	0xFFFFFFF4	Error during message decryption
secCmdRsaHashAlreadyWritten	0xFFFFFFEE	RSA hash already written in OTP

17.2.6.4.Command Description

17.2.6.4.1.Read ROM Code Version

For this specific command, the Secure SAM-BA Monitor replies with the SVER opcode, and indicates that the ROM code version string length is 30 bytes, so the external tool knows how many characters should be received.

(PC to device) >> `RVER,0,0,0,00#`

(Device to PC) << `SVER,00000000,00000030#v1.0.p1.Feb 23 2021.18:35:56...`

17.2.6.4.2.Write Customer Key

Sending the customer key to the chip involves sending a binary payload (the ciphered message containing the customer key). This payload must be sent by the tool after receiving acknowledgment from the Monitor, showing how many bytes are expected.

(PC to device) >> `WCKY,0,70,0,01#`

(Device to PC) << `CACK,00000000,00000070#`

(PC to device) >> `<key_file.cip>`

(Device to PC) << `CACK,00000000,00000000#`

17.2.6.4.3.Running a Secure Applet

Secure applets are small programs allowed by the ROM code to run in the internal SRAM of the device. They are ciphered and signed, and only provided by Microchip as part of the SAM-BA tool. They give the possibility to perform more operations than the one provided by the simple Secure Monitor commands.

Several applets are available. For example, external memories can be programmed using memory-programming algorithm applets, the Boot Configuration and Secure Boot Configuration Packets can be programmed using dedicated applet, etc.

The first step is to send the ciphered applet to the target. This is done through the Send Applet command:

(Device to PC) >> `SAPT,0,9870,0,01#`

(Device to PC) << `CACK,00000000,00009870#`

(PC to device) >> `<applet_binary.cip>`

(Device to PC) << `CACK,00000000,00000000#`

In the example above, the host computer requests sending an applet of size 0x9870, and this is acknowledged by the Secure Monitor. Then the host computer sends the applet ciphered binary file (applet_binary.cip), and after checking the signature and deciphering the applet in SRAM, the Secure Monitor sends the acknowledgment message and error code (CACK and error code 0x0: successful).

© 2026 Microchip Technology Inc. and its subsidiaries

Once the applet is in the SRAM, before executing its code, its mailbox must be filled. The mailbox is a 32-word buffer used to exchange commands and arguments with the applet.

The number of commands and arguments in the mailbox can differ from one applet to another, depending on each applet purpose.

To do so, the Send Applet Mailbox command must be issued.

The mailbox is not ciphered, and is automatically written at the correct address by the ROM code.

(PC to device) >> SMBX,0,80,0,01#

(Device to PC) << CACK,00000000,00000080#

(PC to device) >> <applet_init_mailbox.bin>

(Device to PC) << CACK,00000000,00000000#

Now the applet can be run with the Execute Applet command:

(PC to device) >> EAPP,0,0,0,00#

(Device to PC) << ASTA,00000000,00000000#

The Secure Monitor replies with an acknowledgment and a status of the applet execution (0x0: successful).

During this step, the ROM code retrieves the information that will be used when receiving the next Write File command:

- Status of the applet execution
- If applicable, address and size of a data buffer for data exchange between the host computer and the applet (for applets intended to program external Flash memories, for example)

A Send File command can then be issued, with the size:

(PC to device) >> SFIL,0,5000,0,01#

(Device to PC) << CACK,00000000,00004000#

(PC to device) >> <first 0x4000 bytes of the file to be programmed>

(Device to PC) << CACK,00000000,00001000#

(PC to device) >> <next file chunk of 0x1000 bytes>

(Device to PC) << CACK,00000000,00000000#

17.2.7. Secure Boot Mode Recommendations

This section provides recommendations to ensure a good security level when configuring and using the Secure Boot mode, and some bootstrap development information.

17.2.7.1. Configuring Secure Boot Mode

The recommended procedure to configure the Secure Boot mode, using the SAM-BA tool (available on www.microchip.com), is the following:

1. Write the Boot Configuration Packet, with the required boot settings and boot memory interface.
2. Set the Secure Boot mode.
3. Send the customer key.
4. Send the root certificate hash (in case an RSA signature is used).
5. Program the ciphered bootstrap.
6. Program the other application files.

© 2026 Microchip Technology Inc. and its subsidiaries

7. **Disable invalidation of the Boot and Secure Boot Configuration Packets** by writing the corresponding bits in the User Hardware Configuration Packet (see OTP Memory Controller (OTPC)).
8. **Lock the Boot Configuration Packet and the Secure Boot Configuration Packet.**
9. **Disable the Secure SAM-BA Monitor** to avoid any further access.

Note: Keeping the Secure Monitor enabled in order to update the bootstrap in the field or in house is not recommended.

17.2.7.2.Bootstrap Development and Updates

This section provides information about the bootstrap and how to update the ciphered bootstrap on a system already provisioned and having the Secure Monitor disabled.

In order to protect the CBC-ciphered bootstrap from known plain text attacks, it is strongly recommended to follow several common rules:

- Avoid compiling and linking “as is” source code that is publicly available.
- Apply secure software development basic principles (add custom parts, add random data, change objects order, etc.).
- Keep bootstrap sources (binary and ciphered versions) in safe places.
- Keep bootstrap as small and robust as possible to reduce the number of updates.

17.2.7.2.1.Bootstrap Ciphering

Before update, the bootstrap must be ciphered in accordance with the Secure Boot mode selected.

The bootstrap can be prepared using the Secure SAM-BA Cipher tool, and then deployed for an update on all devices.

Securing *.CIP files

Microchip’s Secure SAM-BA Cipher utility outputs encrypted *.cip files for use in provisioning at final manufacturing. As these files contain both customer keys and firmware, they must be securely stored with restricted and controlled access.

17.2.7.2.2.Bootstrap Update in the Field

Case 1: SAM-BA Monitor is disabled (the “MON_DIS” word is filled in the Boot Configuration Packet)

In this case, the bootstrap itself or the customer application must be in charge to update the bootstrap, by writing the new bootstrap in the boot memory in replacement of the existing one.

To do so, the program in charge of the update must be able to:

- retrieve the new ciphered bootstrap,
- erase the existing one,
- program the new one.

Important: The last two operations must not be interrupted, otherwise the boot process could be broken.

Case 2: Secure SAM-BA Monitor is still available (the “MON_DIS” word is zeroed in the Boot Configuration Packet - not recommended for systems in production)

1. Disable the access to the external boot memory (Chip Select pin, Card Detect pin, etc., depending on the chosen boot memory) to prevent its access by the ROM code on the next reboot.
2. Connect a USB cable on the USB device port, or on the UART used as SAM-BA Monitor console terminal.

© 2026 Microchip Technology Inc. and its subsidiaries

3. Reset the chip.
4. Enable access to the external boot memory.
5. Program the bootstrap using the SAM-BA tool.

17.2.7.3. Monitor Disabling by the Bootstrap

It is highly recommended to disable the Secure Monitor feature for systems in production. To do so, the MON_DIS word must be filled and the Boot Configuration Packet must be locked at the production stage.

If that has not been done, writing the “MON_DIS” word can be performed by the bootstrap or by the customer application, but only if the Boot Configuration Packet has not been locked.

To write the “MON_DIS” word and lock the packet, an update of the Boot Configuration Packet in the OTP memory is required. In the section OTP Memory Controller (OTPC), refer to:

- Updating an Existing Packet from the User Interface
- Locking a Packet

17.3. Software Considerations

17.3.1. Bootstrap Size

The maximum size allowed for the bootstrap for this chip is 0x8000 bytes (32 Kbytes).

17.3.2. PUF Activation Code Packet Copy in SRAM

When the ROM code launches a bootstrap or executes the SAM-BA Monitor, the PUF Activation Code is made available for the user application in SRAM0 at address 0x0030FBE8. The total size of this data is 0x3E8 bytes.

Structure:

- First 32 bits at address 0x0030FBE8 are 0x43414B51: “QKAC” in ASCII, "tag" used to identify the beginning of the buffer
- 0x0030FBEC to 0x0030FFCD: 0x3E4 bytes of actual activation code data

17.3.3. Boot Interface

Before jumping to the bootstrap entry address, the ROM code provides some information to the bootstrap in CPU registers:

Register	Content
R4	Boot memory

17.4. Hardware Considerations

The table below provides clock frequencies configured by the ROM code during boot.

Table 17.14. Clock Frequencies During External Memory Boot Sequence

Clock	Frequency
PLLA	1200 MHz
CPU_CLK	600 MHz
MCK	200 MHz
SDMMC (init/operational)	400 kHz/25 MHz
QSPI	50 MHz

The default UART used for ROM code console and SAM-BA Monitor UART link is given below:

Index Value in CONSOLE_IOSET[5:0] Bit	Interface

© 2026 Microchip Technology Inc. and its subsidiaries

0	DBGU

The default can be changed by writing another index in the Boot Configuration Packet (refer to CONSOLE_PIN).

The NVM drivers use several PIOs in Peripheral mode to communicate with external Flash memory devices. Care must be taken when these PIOs are used by the application. The connected devices could be unintentionally driven at boot time, and thus electrical conflicts between the output pins used by the NVM drivers and the connected devices could occur.

The following table contains a list of pins that are driven during the boot program execution. These pins are driven during the boot sequence for a period of less than 1 second if no correct boot program is found. The drive strength of pull-up I/O pins is set to High while the pins are used in Peripheral mode by the ROM code.

Before performing the jump to the application in the internal SRAM, all the PIOs and peripherals used in the boot program are set to their reset state.

Table 17.15. PIO Driven During Boot Program Execution

NVM Bootloader	Peripheral	IO Set	Signal	PIO Line	Pull-up enabled

Memories

18. Overview

18.1. Embedded Memories

18.1.1. Internal SRAM

SAM9X7 Series devices embed 68 Kbytes of high-speed SRAM. SRAM0 (64 KB) is always accessible at address 0x0030 0000. After remap, SRAM0 is also available at address 0x0000 0000. A 4-Kbyte SRAM memory, SRAM1, is used for OTP emulation and is always accessible at address 0x0040 0000.

18.1.2. Internal ROM

The ROM contains a bootloader program mapped at address 0 after reset and the BCH (Bose, Chaudhuri and Hocquenghem) code table mapped at address 0x0010_0000 for NAND Flash ECC correction.

18.1.3. Boot Strategies

Refer to Boot Strategies.

18.2. External Memory

SAM9X7 Series devices offer connections to a wide range of external memories or to parallel peripherals.

18.2.1. External Bus Interface

The External Bus Interface (EBI) is an interface that features:

- Three external memory controllers:
  - a 16-bit Static Memory Controller (SMC)
  - a NAND Flash Controller (NFC)
  - a Multi-Port DDR-SDRAM Controller (MPDDRC) supporting 16-bit DDR3(L)/DDR2
- 8- or 16-bit data bus
- Up to 23-bit address bus
- Up to three chip selects with configurable assignment:
  - Static Memory Controller on NCS0, NCS1, NCS2
  - MPDDRC or Static Memory Controller on NCS1
  - Optional NAND Flash support on NCS2

The drive levels are configured in the EBI I/O Drive Configuration register (SFR_CCFG_EBICSA.EBI_DRIVE) in Special Function Registers (SFR). At reset, the selected drive is low. The user must make sure to program the correct drive. Refer to Electrical Characteristics.

18.2.2. Supported Memories on MPDDRC Interface

The MPDDRC supports the following memories:

- DDR-SDRAM with four or eight internal banks (DDR2-SDRAM or DDR3(L)-SDRAM)
- DDR-SDRAM with 16-bit data path for system-oriented word access
- 2K, 4K, 8K, 16K row address memory parts

© 2026 Microchip Technology Inc. and its subsidiaries

18.2.3. Supported Memories on Static Memories and NAND Flash Interfaces

The SMC supports:

- Asynchronous SRAM-like memories and parallel peripherals
- 8- or 16-bit data bus

The NFC supports:

- 8-bit NAND Flash (SLC)
- 24-bit Programmable Multi-bit Error Correcting Code (PMECC) with dedicated databus NANDDAT0-NANDDAT7

18.3. Product Dependencies

18.3.1. Clocks

Internal memories (SRAM and ROM) and SMC clocks are not controlled by the PMC. MPDDRC and PMECC clocks are controlled by the PMC.

18.3.2. Interrupts

Refer to the table Peripheral Identifiers.

18.3.3. Reset

SMC and NFC are connected to the processor and peripherals reset line.

18.3.4. I/Os

DDR-SDRAM I/Os are high-speed specific I/Os powered by VDDIOM.

18.4. Special Functions in SFR

18.4.1. DDRC Multiport Enabling

The SFR_REMAP_MP_DDR configuration register includes 14 bits, one for each host. The register has the same function as bit DDR_MP_EN in SFR_CCFG_EBICSA, and can be used instead of DDR_MP_EN for more granularity. If DDR_MP_EN is not enabled, each bit in SFR_REMAP_MP_DDR can be used to perform an individual DDR multiport remapping (bit 0 for Host_0, bit 1 for Host_1, etc.).

This register makes port 0 reachable. It is not used when DDR_MP_EN bit is used.

Refer to Bus Matrix (MATRIX) for a description of hosts and clients.

18.4.2. FLEXRAM Clocking

To save power consumption, the SFR_FLEXRAMS_CLKG_DIS register can be used to enable clock gating on both FLEXRAM ports.

18.4.3. Memories Light Sleep Mode

To save power consumption in low-power modes, Light Sleep mode can be enabled in register SFR_LS.

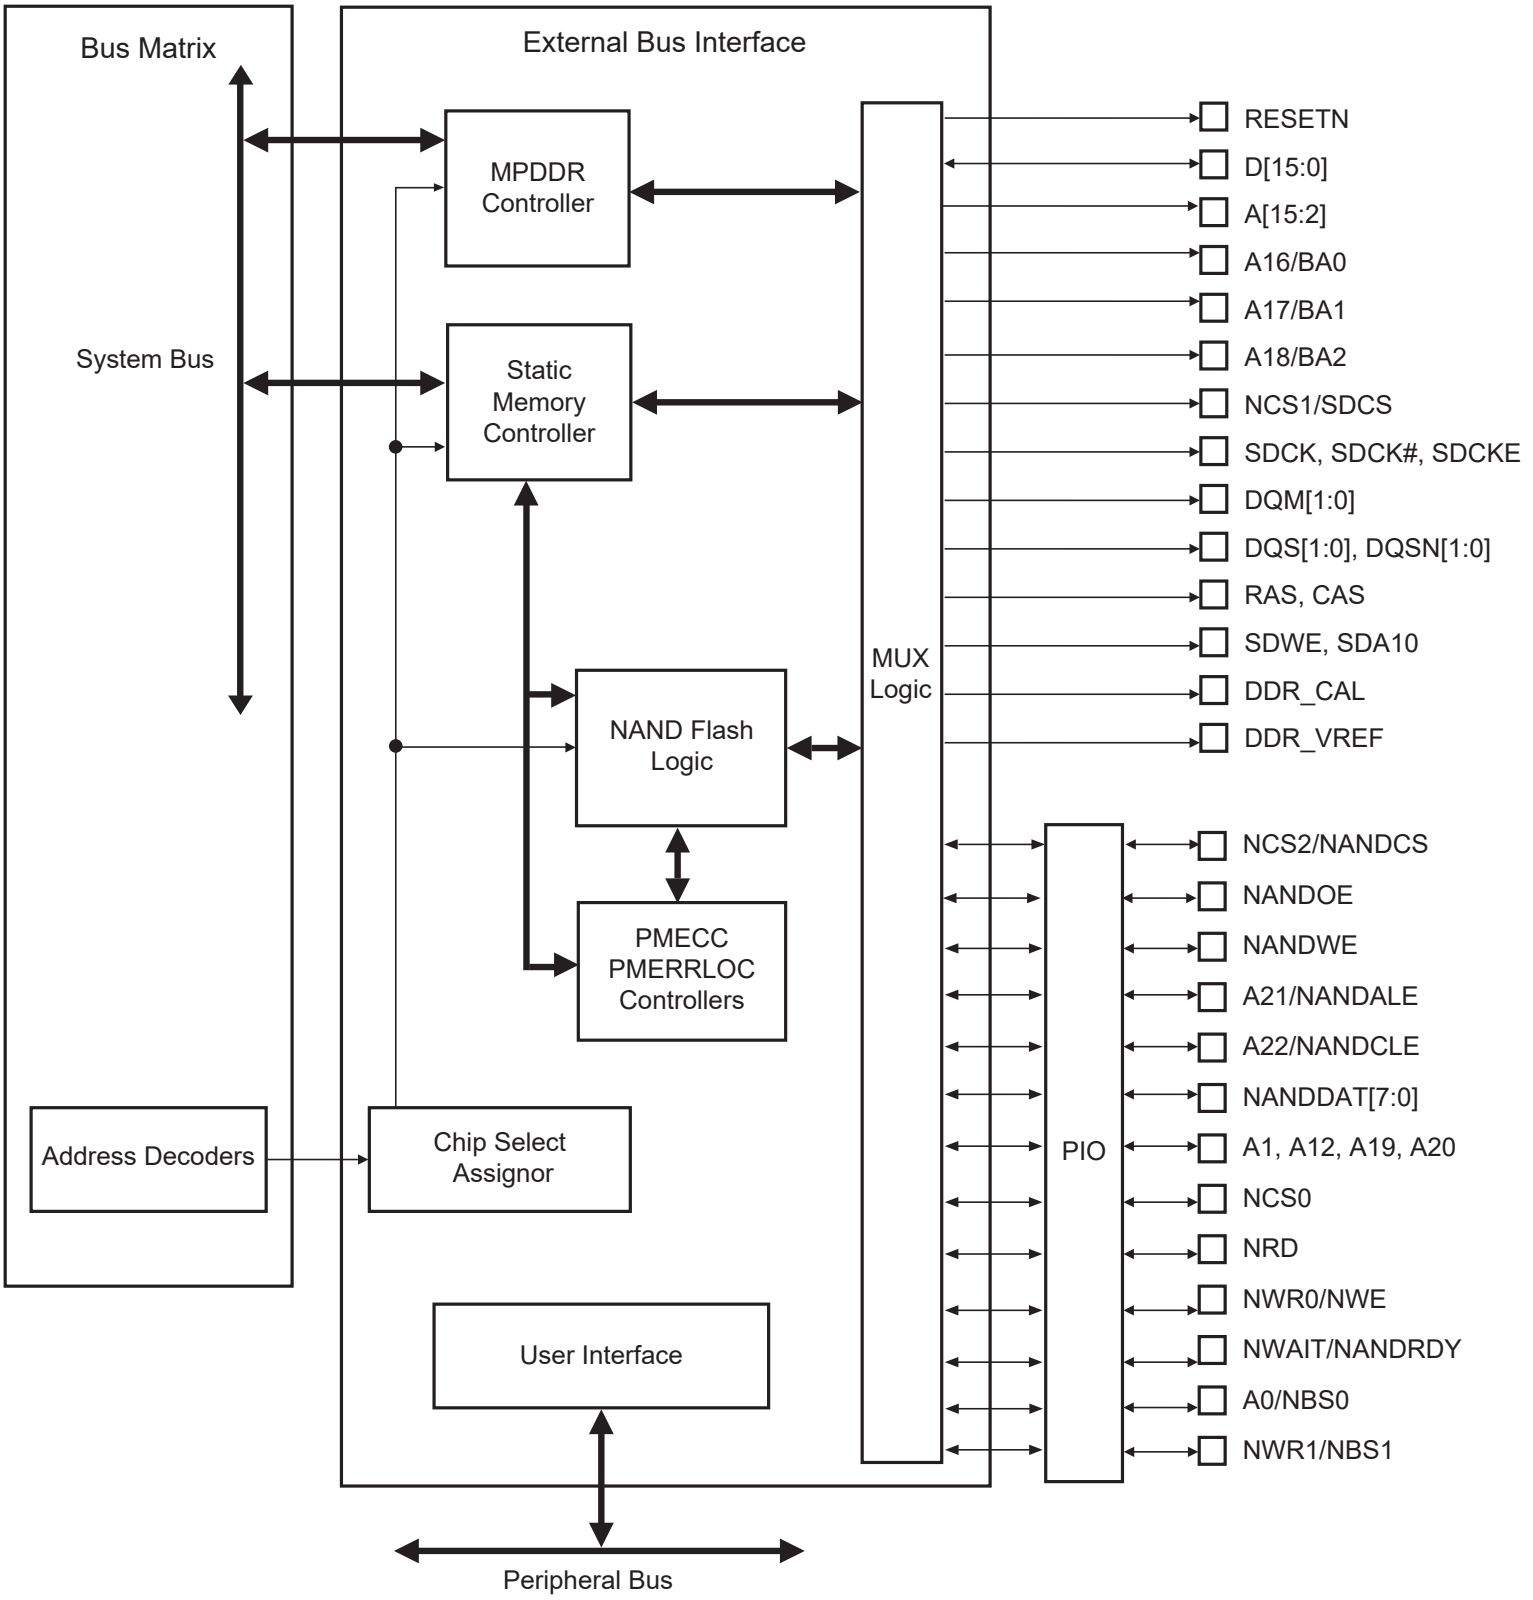
19. External Bus Interface (EBI)

19.1. Description

The External Bus Interface (EBI) is designed to ensure successful data transfers between external devices and the embedded memory controller of the SAM9X7 Series device.

The Static Memory, MPDDR and ECC Controllers are all featured external memory controllers on the EBI. These external memory controllers are capable of handling several types of external memory and peripheral devices, such as SRAM, PROM, EPROM, EEPROM, Flash and DDR3(L)/DDR2 SDRAM.

The EBI also supports the NAND Flash protocols via an integrated circuitry that greatly reduces the requirements for external components. Furthermore, the EBI handles data transfers with up to three external devices, each assigned to three address spaces defined by the embedded memory controller. Data transfers are performed through a 16-bit data bus, an address bus of up to 23 bits, up to three chip select lines (NCS[2:0]) and several control pins that are generally multiplexed between the different external memory controllers.



19.2. Embedded Characteristics

- Integrates Three External Memory Controllers:
  - Static memory controller
  - MPDDR controller
  - 8-bit NAND Flash ECC controller
- Up to 23-bit Address Bus (up to 64 Mbytes linear per chip select)
- Up to Three Chip Selects with Configurable Assignment:
  - Static memory controller on NCS0, NCS1, NCS2
  - MPDDR/SDRAM controller on NCS1 (SDCS)
  - NAND Flash support on NCS2 (NANDCS)

Note:

1. The NFD0_ON_D16 switch is used to select NAND Flash path on D[7:0] or NANDDAT[7:0] depending on memory power supplies. This switch is located in the SFR_CCFG_EBICSA register in the Special Function Register.

19.5.2. Product Dependencies

19.5.2.1. I/O Lines

The pins used for interfacing the External Bus Interface may be multiplexed with the PIO lines. The programmer must first program the PIO controller to assign the External Bus Interface pins to their peripheral function. If I/O lines of the External Bus Interface are not used by the application, they can be used for other purposes by the PIO Controller.

19.5.3. Functional Description

The EBI transfers data between the internal AHB Bus (handled by the Bus Matrix) and the external devices (memories, FPGA, etc.). It controls the waveforms and the parameters of the external address, data and control buses and is composed of the following elements:

- Static Memory Controller (SMC)
- MPDDR Controller (MPDDRC)
- Programmable Multibit ECC Controller (PMECC)
- A chip select assignment feature that assigns an AHB address space to the external devices
- A multiplex controller circuit that shares the pins between the different Memory Controllers
- Programmable NAND Flash support logic

19.5.3.1. Bus Multiplexing

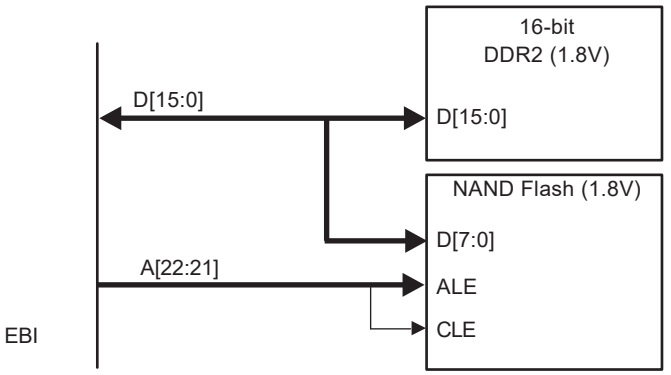
The EBI offers a complete set of control signals that share the 16-bit data lines, the address lines of up to 23 bits and the control signals through a multiplex logic operating in function of the memory area requests.

Multiplexing is specifically organized in order to guarantee the maintenance of the address and output control lines at a stable state while no external access is being performed. Multiplexing is also designed to respect the data float times defined in the Memory Controllers.

© 2026 Microchip Technology Inc. and its subsidiaries

19.5.3.2.Pull-Up and Pull-Down Control

The SFR_CCFG_EBICSA register in the Special Function Register User Interface enable on-chip pull-up and pull-down resistors on data bus lines not multiplexed with the PIO Controller lines. The pull-down resistors are enabled after reset. The bits, EBIx_DBPUC and EBI_DBPDC, control the pull-up and pull-down resistors on the D[15:0] lines.



19.5.3.3.Power Supplies

The product embeds a dual power supply for the EBI: VDDNF for NAND Flash signals, and VDDIOM for other signals. This makes it possible to use a 1.8V or 3.3V NAND Flash independently of the SDRAM power supply.

The switch NFD0_ON_D16 is used to select the NAND Flash path on D[7:0] or NANDDAT[7:0] depending on memory power supplies. This switch is located in the SFR_CCFG_EBICSA register (refer to Special Function Registers (SFR)). At reset NFD0_ON_D16 = 0 and the NAND Flash bus is connected to D[7:0].

The following figure illustrates an example of the NAND Flash and the external RAM (DDR2) in the same power supply range (NFD0_ON_D16 = default).

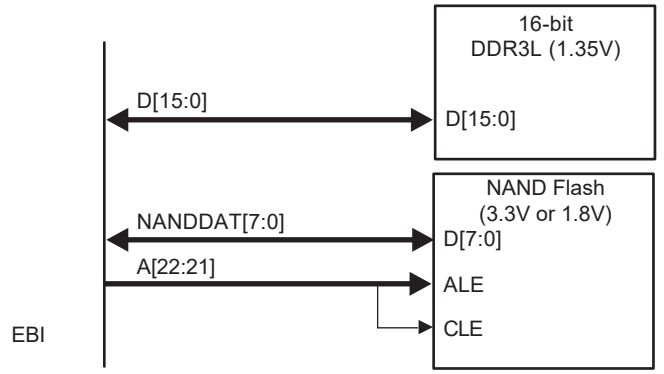


Figure 19.2. NAND Flash and External RAM in Same Power Supply Range (NFD0_ON_D16 = default)

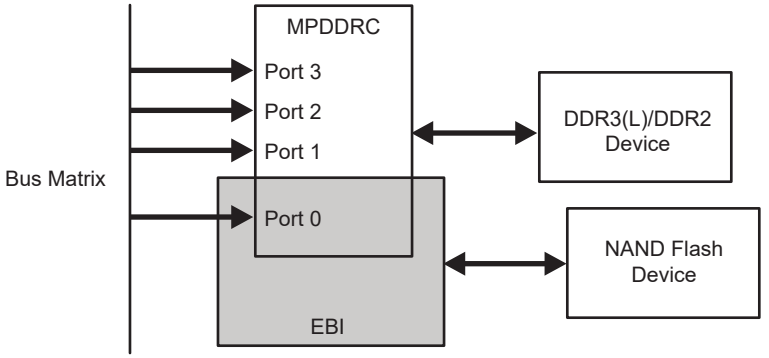
The following figure illustrates an example of the NAND Flash and the external RAM (DDR3L) NOT in the same power supply range (NFD0_ON_D16 = 1).

This can be used if the SMC connects to the NAND Flash only. Using this function with another device on the SMC will lead to an unpredictable behavior of that device. In that case, the default value must be selected.

Figure 19.3. NAND Flash and External RAM Not in Same Power Supply Range (NFD0_ON_D16 = 1)

© 2026 Microchip Technology Inc. and its subsidiaries

19.5.3.4. Static Memory Controller



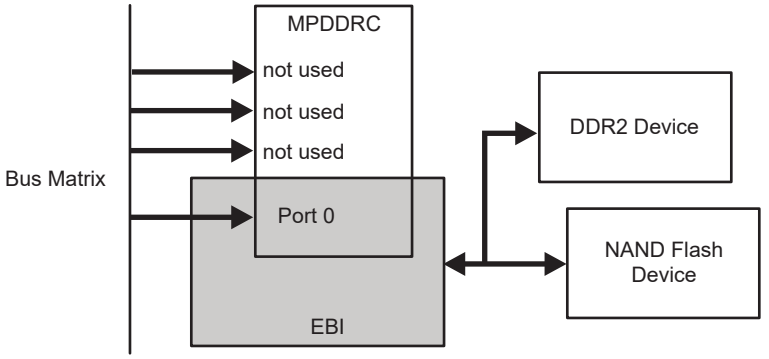
For information, refer to Static Memory Controller (SMC)

19.5.3.5. Multi-Port DDR and SDRAM Controllers

The product embeds a multi-port DDR Controller. This allows to use three additional ports on the MPDDRC to lessen the EBI load from a part of SDRAM accesses. This increases the bandwidth when DDR3(L)/DDR2 and NAND Flash devices are used.

It is controlled by the DDR_MP_EN bit in EBI Chip Select Assignment Register.

Figure 19.4. Multi-Port Enabled MPDDRC (DDR_MP_EN = 1)



When:

- a NAND Flash memory is connected to NANDDAT[7:0] and
- a DDR2-SDRAM is connected to D[15:0],

the bits SFR_CCFG_EBICSA.DDR_MP_EN and SFR_CCFG_EBICSA.NFD0_ON_D16 must both be set before performing the SDRAM initialization.

Figure 19.5. Multi-Port Disabled MPDDRC (DDR_MP_EN = 0)

19.5.3.6. Programmable Multibit ECC Controller

For information on the PMECC Controller, refer to Programmable Multibit Error Correction Code Controller (PMECC) and Programmable Multibit ECC Error Location Controller (PMERRLOC). Also refer to NAND Flash Boot: PMECC Error Detection and Correction.

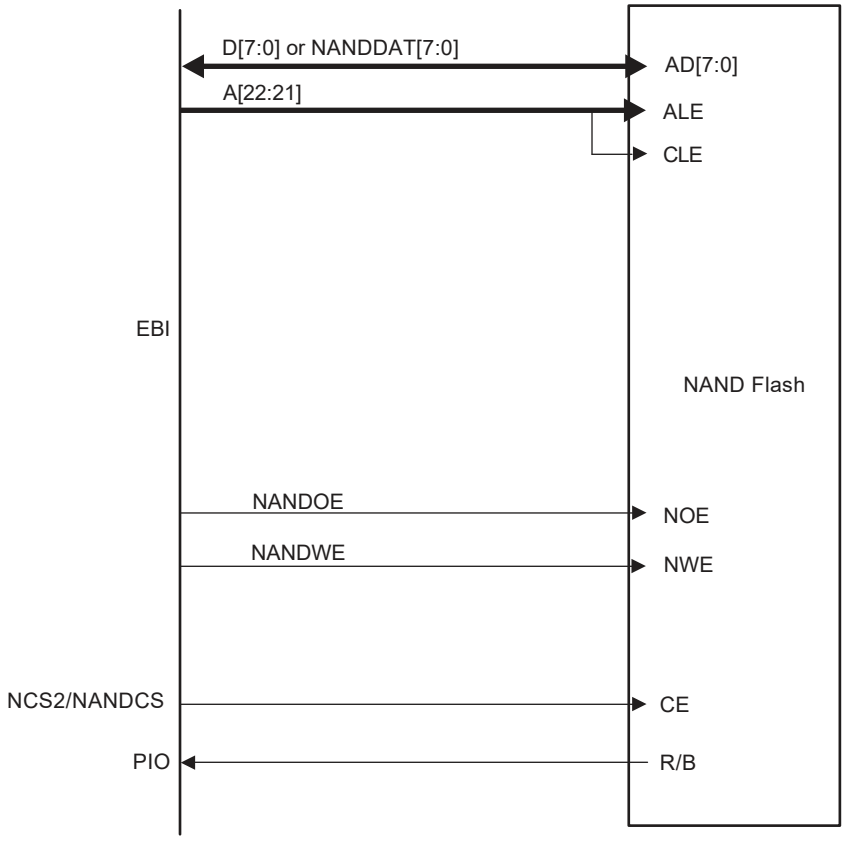
19.5.3.7. NAND Flash Support

External Bus Interfaces integrate circuitry that interfaces to NAND Flash devices.

External Bus Interface

The NAND Flash logic is driven by the Static Memory Controller on the NCS2 address space. Programming the EBI_CS2A field in the SFR_CCFG_EBICSA Register in the SFR User Interface to the

© 2026 Microchip Technology Inc. and its subsidiaries



appropriate value enables the NAND Flash logic. For details on this register, refer to Special Function Registers (SFR). Access to an external NAND Flash device is then made by accessing the address space reserved to NCS2 (i.e., between 0x3000 0000 and 0x3FFF FFFF).

The NAND Flash Logic drives the read and write command signals of the SMC on the NANDOE and NANDWE signals when the NCS2 signal is active. NANDOE and NANDWE are invalidated as soon as the transfer address fails to lie in the NCS2 address space. See the figure below for more information. For details on these waveforms, refer to Static Memory Controller (SMC).

NAND Flash Signals

The address latch enable and command latch enable signals on the NAND Flash device are driven by address bits A22 and A21 of the EBI address bus. The command, address or data words on the data bus of the NAND Flash device are distinguished by using their addresses within the NCSx address space. The chip enable (CE) signal of the device and the ready/busy (R/B) signals are connected to PIO lines. The CE signal then remains asserted even when NCSx is not selected, preventing the device from returning to Standby mode.

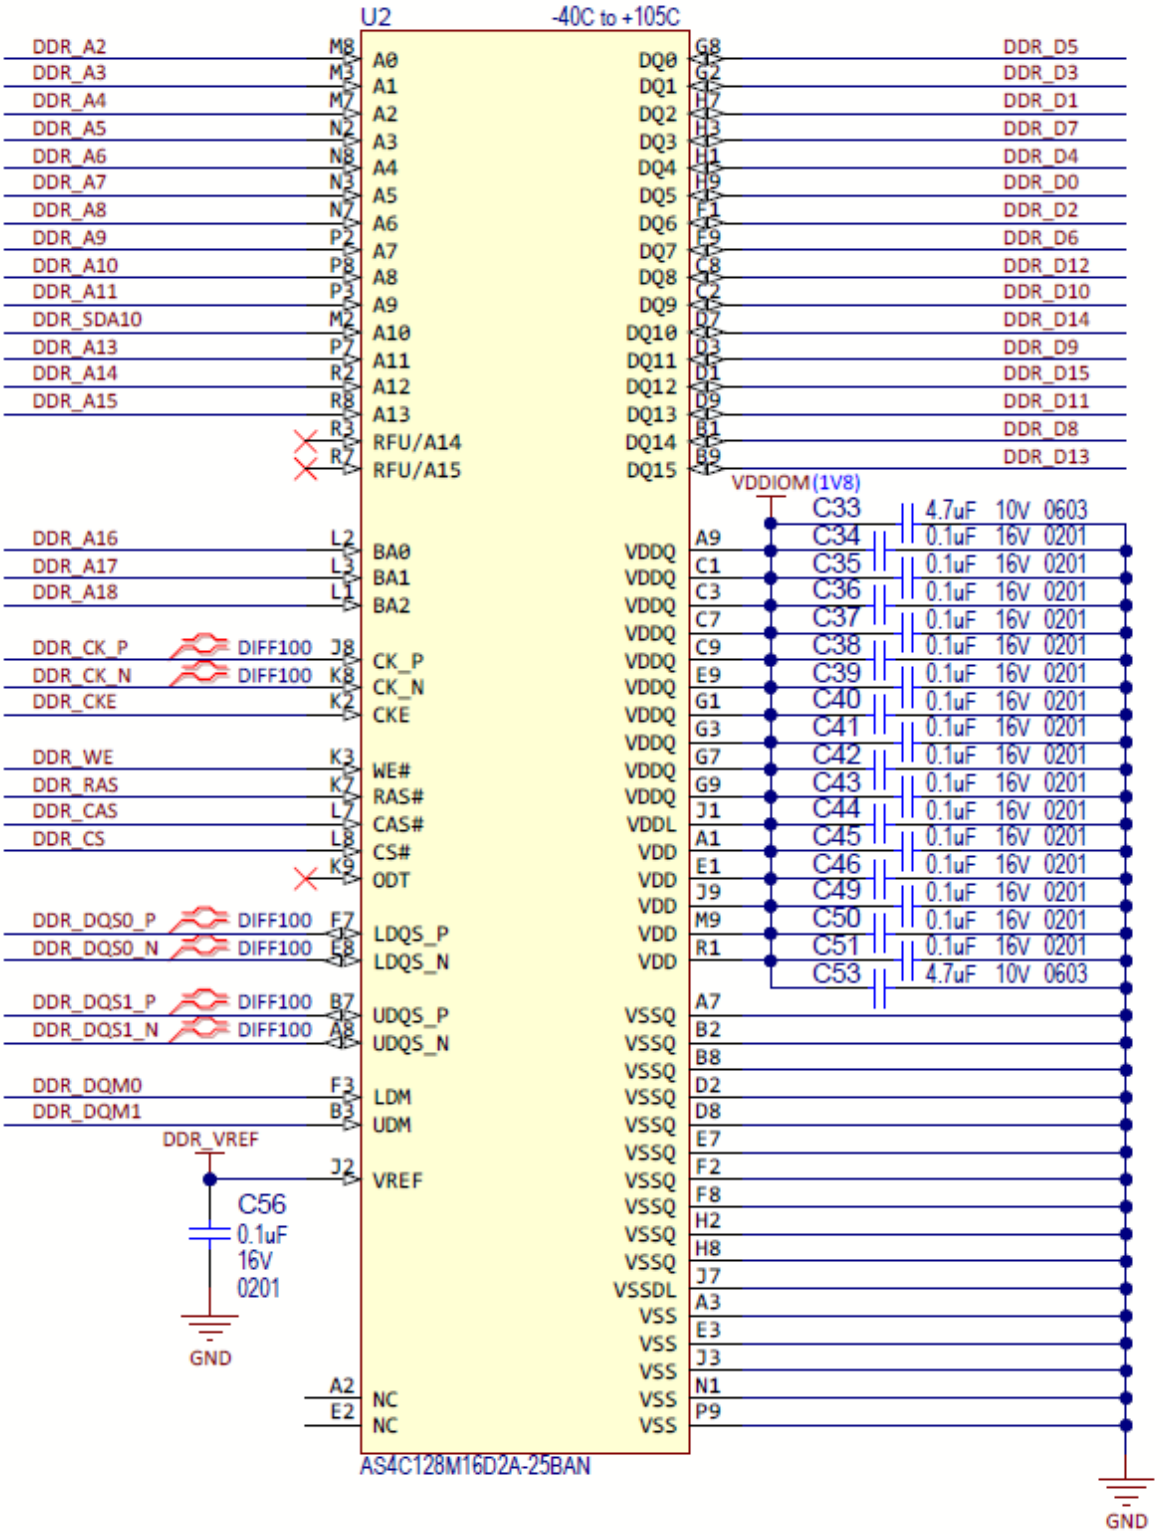
Figure 19.6. NAND Flash Application Example

Note: The CE signal of the NAND Flash must be connected to PIOD4 (NCS2/NANDCS) if the user's system boots out of NAND Flash.

19.5.4. Implementation Examples

The following hardware configurations are given for illustration only. The user should refer to the memory manufacturer web site to check current device availability.

© 2026 Microchip Technology Inc. and its subsidiaries



19.5.4.1.1x16-bit DDR2 on EBI NCS1

19.5.4.1.1.Hardware Configuration

This configuration shows DDR2-SDRAM with a 1.8V power supply. The same configuration can apply to DDR3L-SDRAM with a 1.35V power supply.

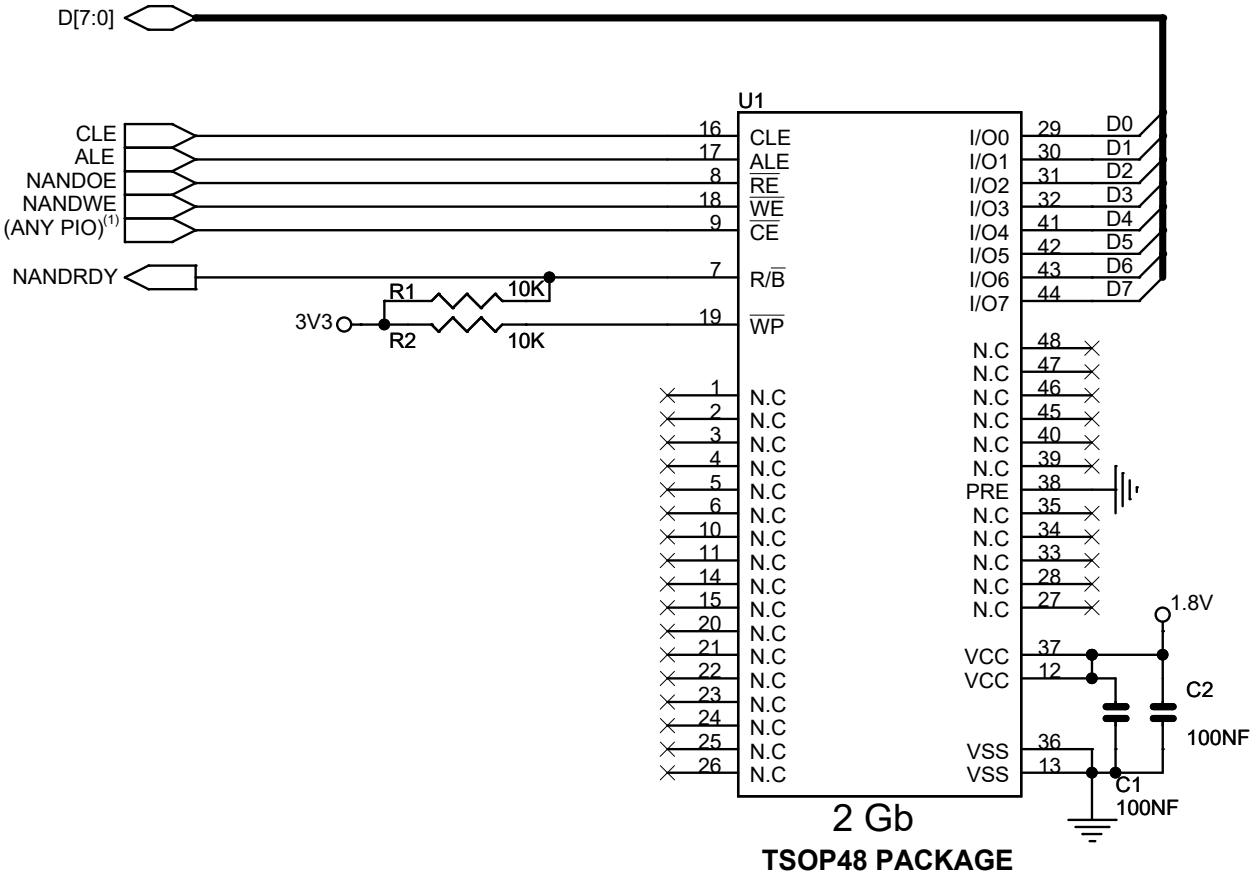
© 2026 Microchip Technology Inc. and its subsidiaries

Figure 19.7. Configuration Example: 16-bit DDR2 on EBI NCS1

© 2026 Microchip Technology Inc. and its subsidiaries

19.5.4.1.2.Software Configuration

- Assign EBI_CS1 to the MPDDRC controller by setting the EBI_CS1A bit in the SFR_CCFG_EBICSA register.
- Initialize the MPDDR Controller depending on the DDR2 device and system bus frequency.



The DDR2 initialization sequence is described in the subsection “DDR2 Device Initialization” of DDR-SDRAM Controller (MPDDRC).

19.5.4.2.Additional 1.8V 8-bit NAND Flash on NCS2 with NFD0_ON_D16 = 0, with DDR2-SDRAM

19.5.4.2.1.Hardware Configuration

In this configuration NAND Flash and DDR2-SDRAM are on the same data bus, with the same power supply. As DDR2-SDRAM is used, NAND Flash must be 1.8V powered. So, VDDIOM and VDDNF must be set to 1.8V.

Figure 19.8. Configuration Example: Additional 1.8V 8-bit NAND Flash on NCS2 with NFD0_ON_D16 = 0, with DDR2-SDRAM

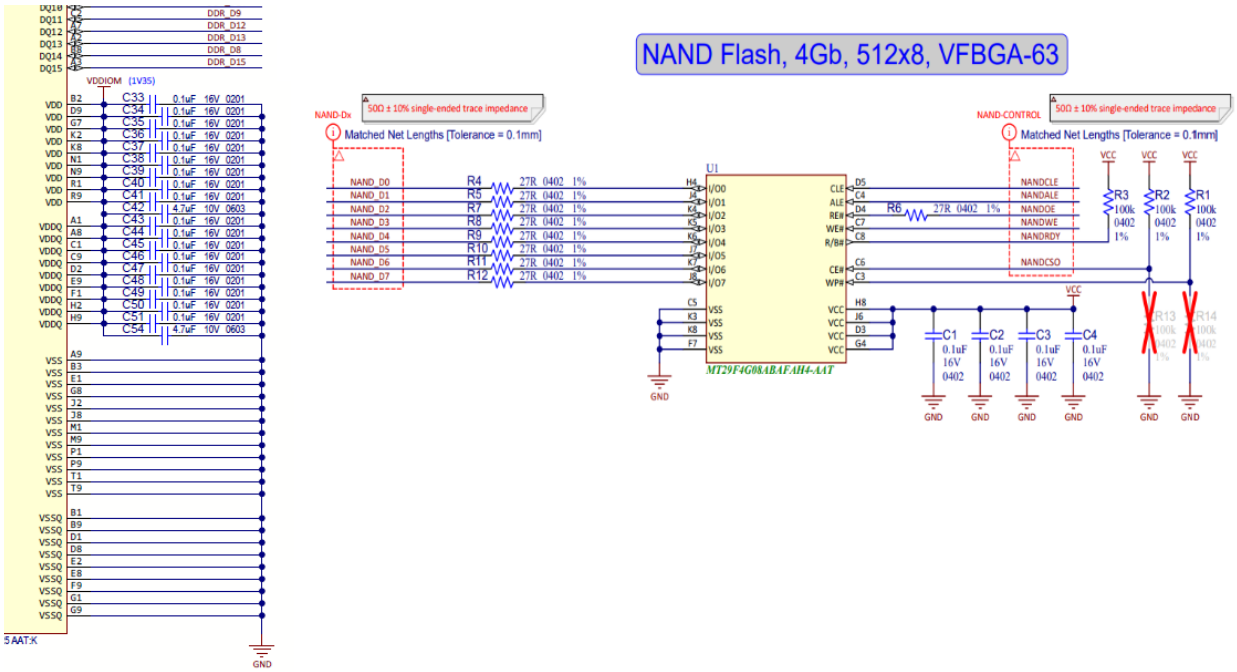
(1) The CE must be connected to NCS2 PIOD4 if the NAND Flash is used by the ROM code.

Note: The CE signal of the NAND Flash must be connected to PIOD4 (NCS2/NANDCS) if the user's system boots out of NAND Flash.

19.5.4.2.2.Software Configuration

The following configuration has to be performed:

© 2026 Microchip Technology Inc. and its subsidiaries



- Set NFD0_ON_D16 = 0 in the SFR_CCFG_EBICSA register.
- Assign the EBI CS2 to the NAND Flash by setting the EBI_CS2A bit in the SFR_CCFG_EBICSA register.
- Reserve A21/A22 for ALE/CLE functions. Address and Command Latches are controlled respectively by setting to 1 the address bits A21 and A22 during accesses.
- Configure PD14 as an input to manage the Ready/Busy signal.
- Configure Static Memory Controller CS2 Setup, Pulse, Cycle and Mode according to NAND Flash timings, data bus width and system bus frequency.

19.5.4.3.16-bit DDR2/3L on NCS1 and 8-bit NAND Flash on NCS2 with NFD0_ON_D16 = 1 (1.8V or 3.3V)

19.5.4.3.1.Hardware Configuration

In this configuration, NAND Flash and DDR2-SDRAM are not on the same data bus and use separate power supplies. DDR2-SDRAM is shown, but the same configuration applies to DDR3L-SDRAM with a 1.35V VDDIOM power supply. NAND Flash is separately powered by VDDNF and can be 1.8V or 3.3V powered.

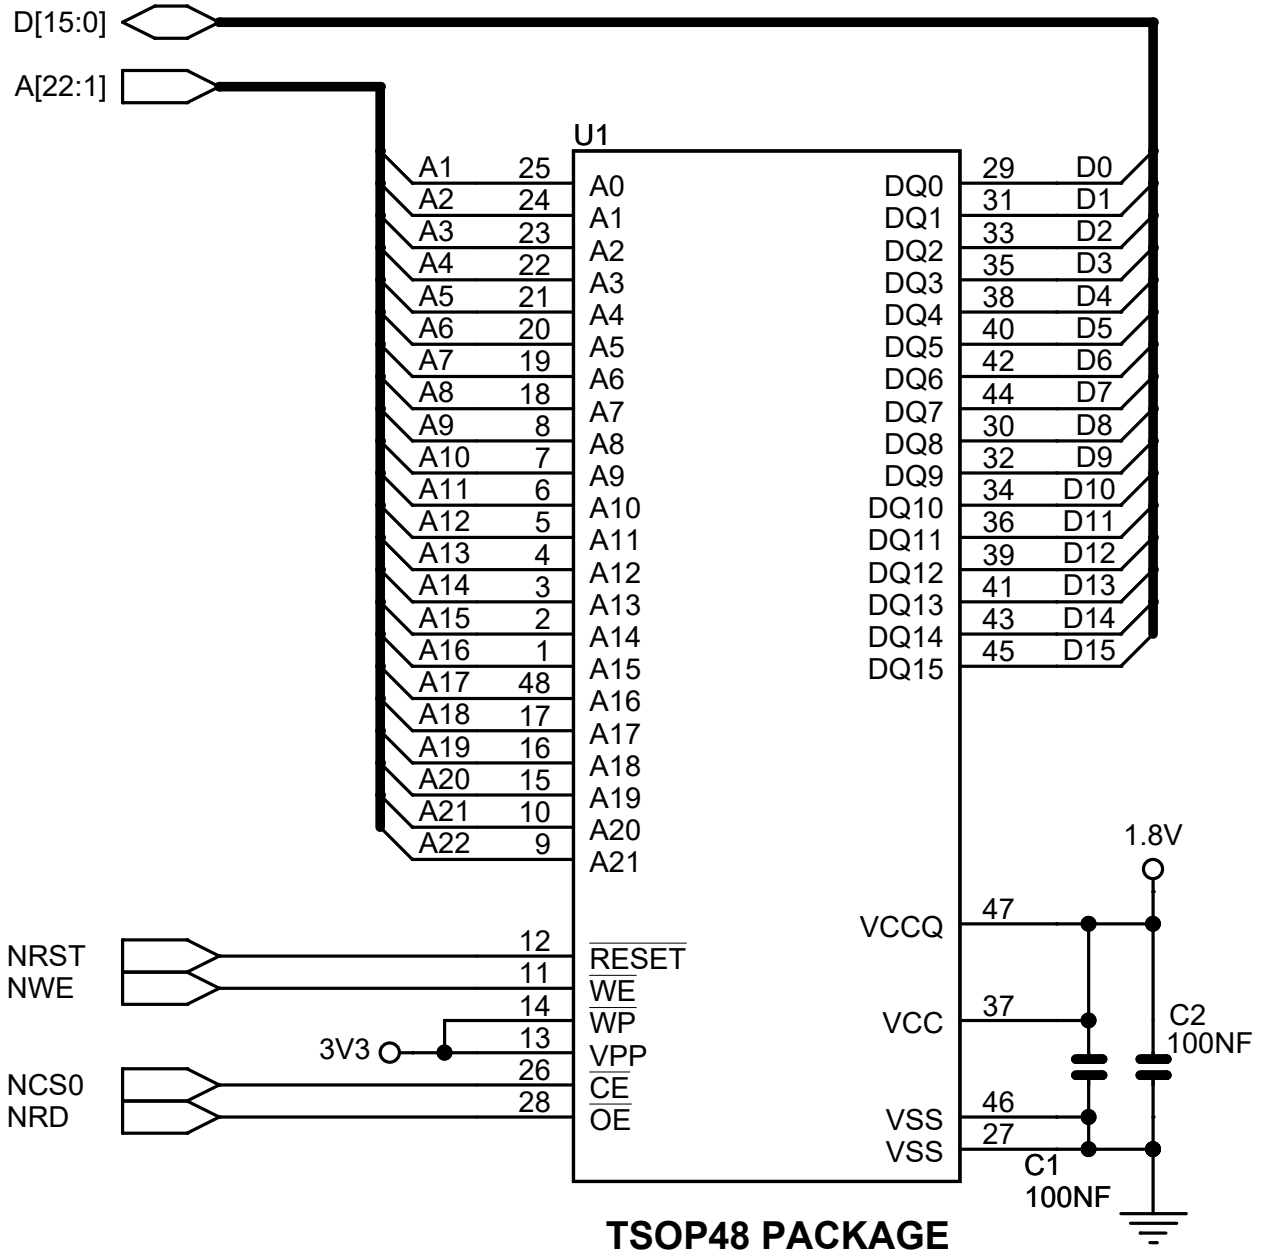
Figure 19.9. Configuration Example: 16-bit DDR2/3L on NCS1 and 8-bit NAND Flash on NCS2 with NFD0_ON_D16 = 1 (1.8V or 3.3V)

19.5.4.3.2.Software Configuration

The following configuration must be performed:

1. Set NFD0_ON_D16 = 1 in the SFR_CCFG_EBICSA register.
2. Assign the EBI CS2 to the NAND Flash by setting the EBI_CS2A bit in the SFR_CCFG_EBICSA register.
3. Reserve A21 / A22 for ALE / CLE functions. Address and Command Latches are controlled respectively by setting to 1 the address bits A21 and A22 during accesses.
4. Configure PD14 as an input to manage the Ready/Busy signal.

© 2026 Microchip Technology Inc. and its subsidiaries



5. Configure Static Memory Controller CS2 Setup, Pulse, Cycle and Mode according to NAND Flash timings, data bus width and system bus frequency.

19.5.4.4.NOR Flash on NCS0

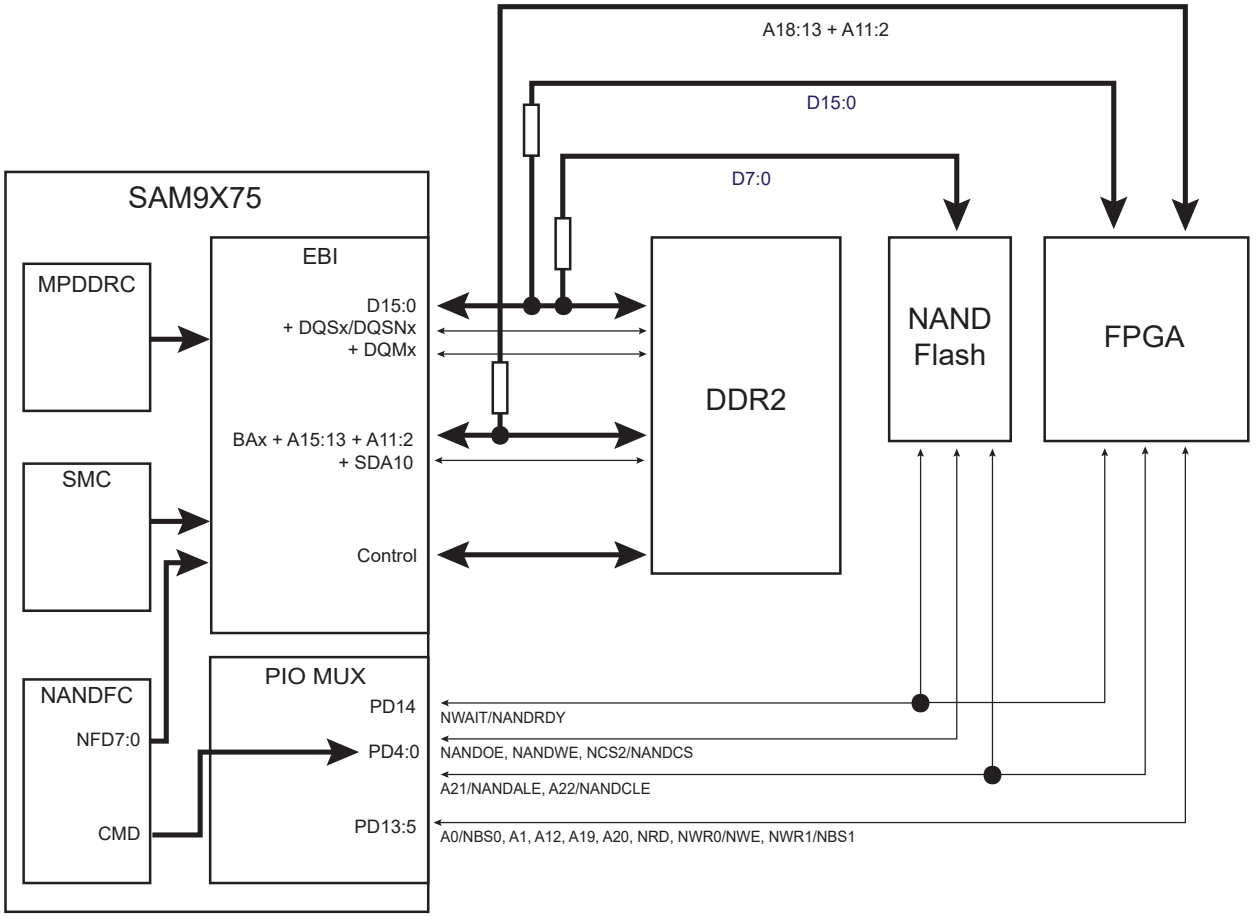
19.5.4.4.1.Hardware Configuration

In this configuration, NOR Flash and DDR2-SDRAM are on the same data bus and use the same power supply. As DDR2-SDRAM is used, NOR Flash must be 1.8V powered. As some control signals are powered by the VDDNF domain, this configuration forces VDDNF to be powered at 1.8V like VDDIOM.

Figure 19.10. Configuration Example: NOR Flash on NCS0

19.5.4.4.2.Software Configuration

The default configuration for the Static Memory Controller, Byte Select mode, 16-bit data bus, Read/Write controlled by Chip Select, allows boot on 16-bit non-volatile memory at slow clock.



© 2026 Microchip Technology Inc. and its subsidiaries

For another configuration, configure the Static Memory Controller CS0 Setup, Pulse, Cycle and Mode depending on Flash timings and system bus frequency.

19.5.4.5. Device (FPGA, Static Memory, etc.) on NCS0, DDR on NCS1 and NAND Flash on NCS2

In this configuration, the device on NCS0, DDR2-SDRAM and NAND Flash are on the same data bus and use the same power supply. As DDR2-SDRAM is used, all components attached to the EBI must be 1.8V powered. NFD0_ON_D16 must be set to 0 in this configuration (NFD0_ON_D16 = 1 is a forbidden configuration with three devices on the EBI). As a few control signals are powered by the VDDNF domain, this configuration forces VDDNF to be powered at 1.8V like VDDIOM. Note this configuration is not supported when using DDR3L-SDRAM.

Figure 19.11. Configuration Example: FPGA on NCS0, DDR on NCS1 and NAND Flash on NCS2

Note: For signal integrity purposes, it is good practice to give priority on the PCB layout to the Processor - DDR2 interface and to isolate this interface from the FPGA and the NAND Flash with serial resistors in the 50 to 200 Ohms range. This configuration implies speed limitation on both the DDR2 interface depending on the layout performance and the device connected to the bus. A signal integrity board simulation must be performed to assess the expected speed operation.

© 2026 Microchip Technology Inc. and its subsidiaries

20. Static Memory Controller (SMC)

20.1. Description

The Static Memory Controller (SMC) generates the signals that control the access to the external memory devices or peripheral devices. It has 3 Chip Selects and a 23-bit address bus. The 16-bit data bus can be configured to interface with 8- or 16-bit external devices. Separate read and write control signals allow for direct memory and peripheral interfacing. Read and write signal waveforms are fully parametrizable.

The SMC can manage wait requests from external devices to extend the current access. The SMC is provided with an automatic Slow Clock mode. In Slow Clock mode, it switches from user-programmed waveforms to slow-rate specific waveforms on read and write signals. The SMC supports asynchronous burst read in Page mode access for page sizes up to 32 bytes.

20.2. Embedded Characteristics

- 3 Chip Selects Available
- 8-Mbyte Address Space per Chip Select
- 8- or 16-bit Data Bus
- Word, Halfword, Byte Transfers
- Byte Write or Byte Select Lines
- Programmable Setup, Pulse And Hold Time for Read Signals per Chip Select
- Programmable Setup, Pulse And Hold Time for Write Signals per Chip Select
- Programmable Data Float Time per Chip Select
- External Wait Request
- Automatic Switch to Slow Clock Mode
- Asynchronous Read in Page Mode Supported: Page Size Ranges from 4 to 32 Bytes
- Functional Safety - Protection, Monitors and Reports:
  - Register Write Protection
  - Abnormal Software Access and Sequencer Integrity Error Reports

20.3. I/O Lines Description

Table 20.1. I/O Lines Description

Name	Description	Type	Active Level
NCS[2:0]	Static Memory Controller Chip Select Lines	Output	Low
NRD	Read Signal	Output	Low
NWR0/NWE	Write 0/Write Enable Signal	Output	Low
A0/NBS0	Address Bit 0/Byte 0 Select Signal	Output	Low
NWR1/NBS1	Write 1/Byte 1 Select Signal	Output	Low
A[22:2]	Address Bus	Output	–
D[15:0]	Data Bus	I/O	–
NWAIT	External Wait Signal	Input	Low

20.4. Interrupt Source

The SMC has an interrupt line connected to the interrupt line of the external bus interface. The external bus interface (SMC) interrupt line is connected to the interrupt controller. The external bus interface interrupt line can be triggered by SMC.

© 2026 Microchip Technology Inc. and its subsidiaries

20.5. Multiplexed Signals

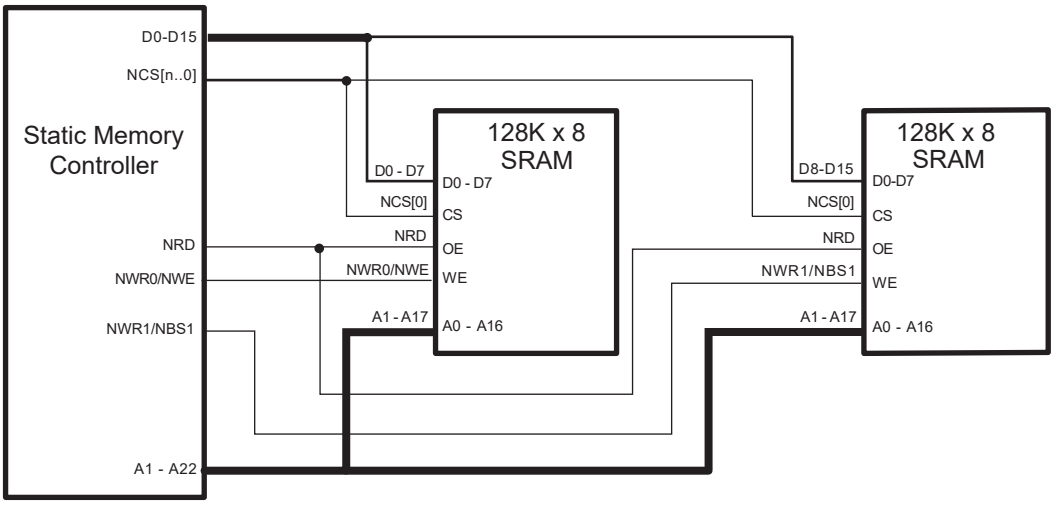


Table 20.2. Static Memory Controller (SMC) Multiplexed Signals

Multiplexed Signals			Related Function
NWR0	NWE	–	Byte-write or byte-select access, see Byte Write or Byte Select Access.
A0	NBS0	–	8-bit or 16-bit data bus, see Data Bus Width.
NWR1	NBS1	–	Byte-write or byte-select access, see Byte Write or Byte Select Access.

20.6. Application Example

20.6.1. Hardware Interface

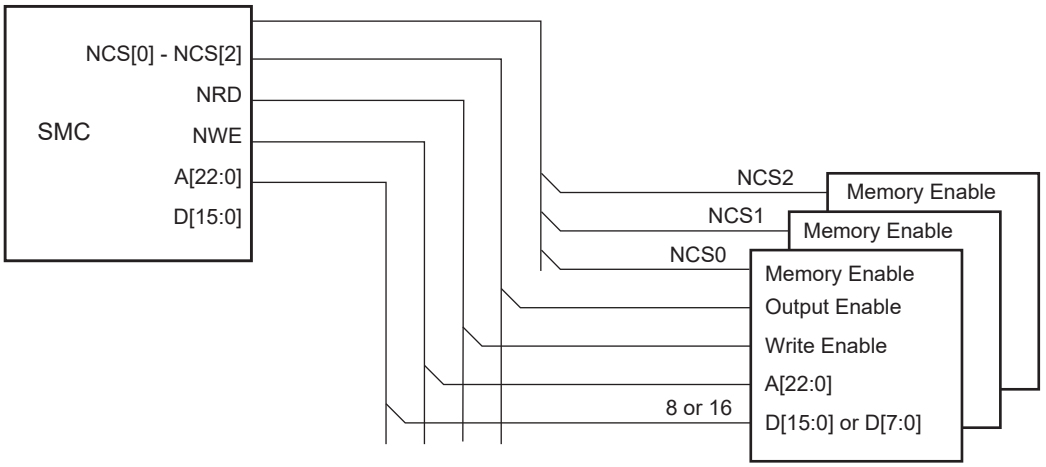
Figure 20.1. SMC Connections to Static Memory Devices

20.7. Product Dependencies

20.7.1. I/O Lines

The pins used for interfacing the Static Memory Controller may be multiplexed with the PIO lines. The programmer must first program the PIO controller to assign the Static Memory Controller pins to their peripheral function. If I/O Lines of the SMC are not used by the application, they can be used for other purposes by the PIO controller.

20.8. External Memory Mapping



The SMC provides up to 23 address lines, A[22:0]. This allows each chip select line to address up to 8 Mbytes of memory.

If the physical memory device connected on one chip select is smaller than 8 Mbytes, it wraps around and appears to be repeated within this space. The SMC correctly handles any valid access to the memory device within the page (see the figure below).

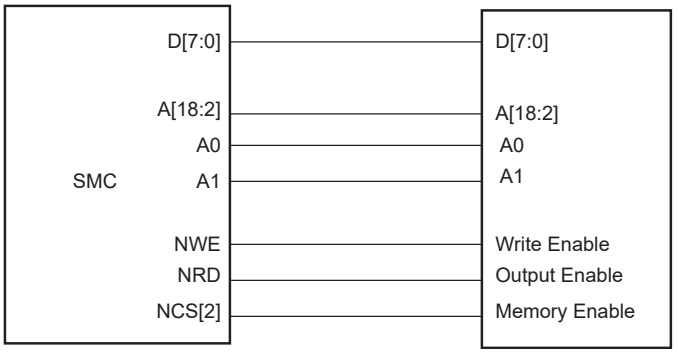
A[22:0] is only significant for an 8-bit memory, A[22:1] is used for a 16-bit memory.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 20.2. Memory Connections for External Devices

20.9. Connection to External Devices

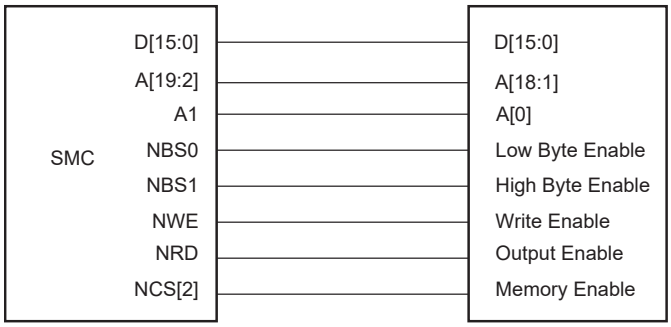
20.9.1. Data Bus Width



A data bus width of 8 or 16 bits can be selected for each chip select. This option is controlled by the field DBW in the Mode register (SMC_MODE) for the corresponding chip select.

- Figure 20.3 illustrates how to connect a 512K x 8-bit memory on NCS2.
- Figure 20.4 illustrates how to connect a 512K x 16-bit memory on NCS2.

20.9.2. Byte Write or Byte Select Access



Each chip select with a 16-bit data bus can operate with one of two different types of write access: byte write or byte select access. This is controlled by the BAT field of the SMC_MODE register for the corresponding chip select.

Figure 20.3. Memory Connection for an 8-bit Data Bus

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 20.4. Memory Connection for a 16-bit Data Bus

20.9.2.1. Byte Write Access

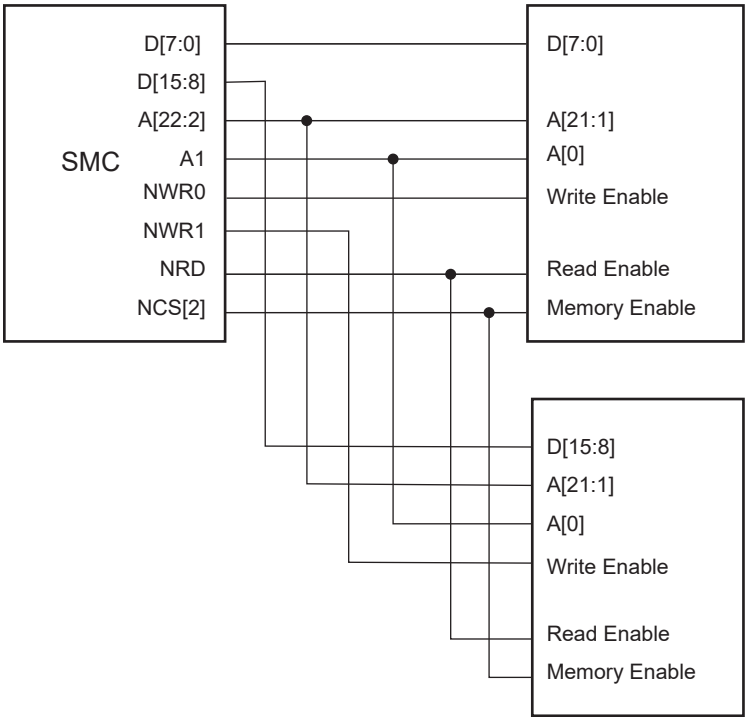
Byte Write Access supports one byte write signal per byte of the data bus and a single read signal.

Note that the SMC does not allow boot in Byte Write Access mode.

For 16-bit devices, the SMC provides NWR0 and NWR1 write signals for respectively byte0 (lower byte) and byte1 (upper byte) of a 16-bit bus. One single read signal (NRD) is provided.

Byte Write Access is used to connect 2 x 8-bit devices as a 16-bit memory.

The Byte Write option is illustrated in Figure 20.5.



20.9.2.2. Byte Select Access

In this mode, read/write operations can be enabled/disabled at a byte level. One byte-select line per byte of the data bus is provided. One NRD signal and one NWE signal control read and write.

For 16-bit devices, the SMC provides NBS0 and NBS1 selection signals for respectively byte0 (lower byte) and byte1 (upper byte) of a 16-bit bus.

Byte Select Access is used to connect one 16-bit device.

Figure 20.5. Connection of 2 x 8-bit Devices on a 16-bit Bus: Byte Write Option

© 2026 Microchip Technology Inc. and its subsidiaries

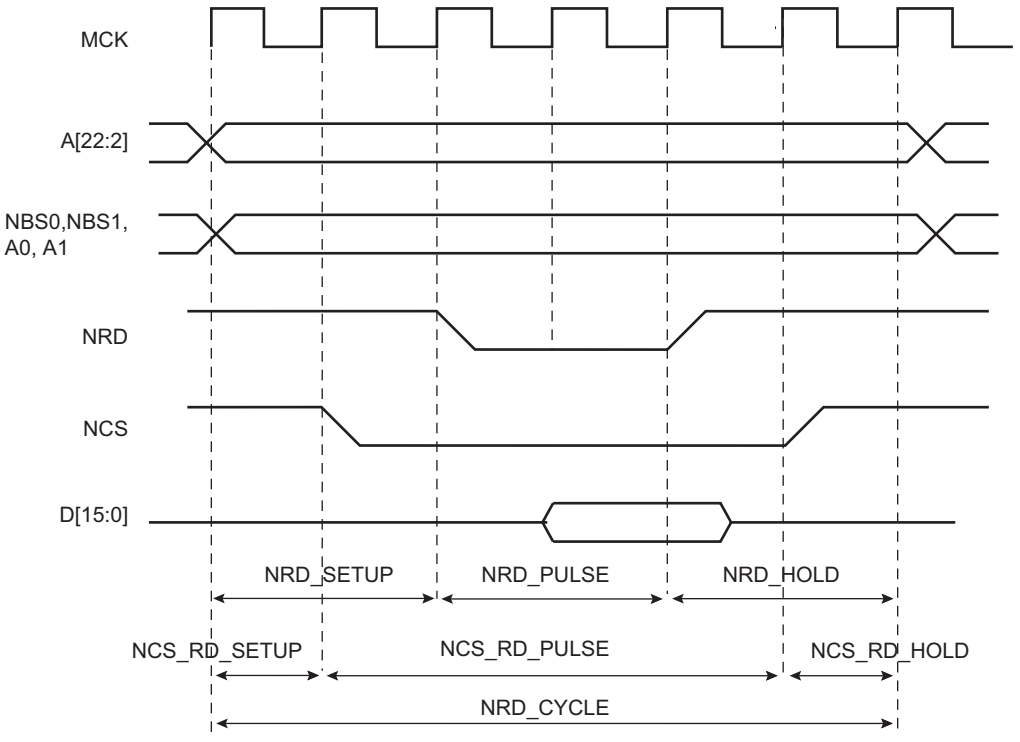
20.9.2.3.Signal Multiplexing

Depending on the Byte Access Type (BAT), only the write signals or the byte select signals are used. To save IOs at the external bus interface, control signals at the SMC interface are multiplexed. The table below shows signal multiplexing depending on the data bus width and the byte access type.

Table 20.3. SMC Multiplexed Signal Translation

Signal Name	16-bit Bus		8-bit Bus
Device Type	1 x 16-bit	2 x 8-bit	1 x 8-bit
Byte Access Type (BAT)	Byte Select	Byte Write	–
NBS0_A0	NBS0	–	A0
NWE_NWR0	NWE	NWR0	NWE
NBS1_NWR1	NBS1	NWR1	–

20.10. Standard Read and Write Protocols



In the following sections, the byte access type is not considered. Byte select lines (NBS0 to NBS1) always have the same timing as the A address bus. NWE represents either the NWE signal in byte select access type or one of the byte write lines (NWR0 to NWR1) in byte write access type. NWR0 to NWR1 have the same timings and protocol as NWE. In the same way, NCS represents one of the NCS[0..2] chip select lines.

20.10.1. Read Waveforms

The following figure shows the read cycle. The read cycle starts with the address setting on the memory address bus:

- {A[22:2], A1, A0} for 8-bit devices
- {A[22:2], A1} for 16-bit devices

Figure 20.6. Standard Read Cycle

20.10.1.1.NRD Waveform

The NRD signal is characterized by a setup timing, a pulse width and a hold timing:

© 2026 Microchip Technology Inc. and its subsidiaries

- NRD_SETUP—NRD setup time is defined as the setup of address before the NRD falling edge.
- NRD_PULSE—NRD pulse length is the time between NRD falling edge and NRD rising edge.
- NRD_HOLD—NRD hold time is defined as the hold time of address after the NRD rising edge.

20.10.1.2.NCS Waveform

Similar to the NRD signal, the NCS signal can be divided into a setup time, pulse length and hold time:

- NCS_RD_SETUP—NCS setup time is defined as the setup time of address before the NCS falling edge.
- NCS_RD_PULSE—NCS pulse length is the time between NCS falling edge and NCS rising edge;
- NCS_RD_HOLD—NCS hold time is defined as the hold time of address after the NCS rising edge.

20.10.1.3.Read Cycle

The NRD_CYCLE time is defined as the total duration of the read cycle, that is, from the time where address is set on the address bus to the point where address may change. The total read cycle time is defined as:

- NRD_CYCLE = NRD_SETUP + NRD_PULSE + NRD_HOLD

as well as

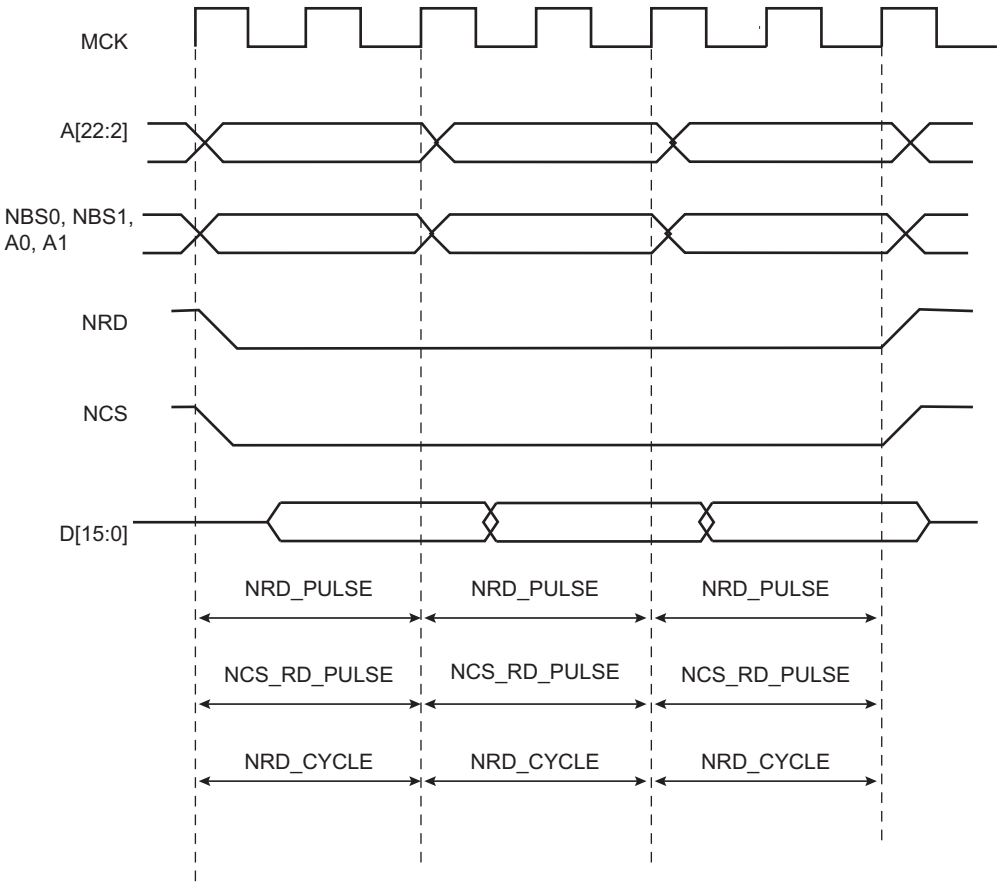
- NRD_CYCLE = NCS_RD_SETUP + NCS_RD_PULSE + NCS_RD_HOLD

All NRD and NCS timings are defined separately for each chip select as an integer number of the main system bus clock cycles. The NRD_CYCLE field is common to both the NRD and NCS signals, thus the timing period is of the same duration.

NRD_CYCLE, NRD_SETUP, and NRD_PULSE implicitly define the NRD_HOLD value as:

- NRD_HOLD = NRD_CYCLE - NRD SETUP - NRD PULSE

NRD_CYCLE, NCS_RD_SETUP, and NCS_RD_PULSE implicitly define the NCS_RD_HOLD value as:



- NCS_RD_HOLD = NRD_CYCLE - NCS_RD_SETUP - NCS_RD_PULSE

20.10.1.4.Null Delay Setup and Hold

If null setup and hold parameters are programmed for NRD and/or NCS, NRD and NCS remain active continuously in case of consecutive read cycles in the same memory. See the following figure.

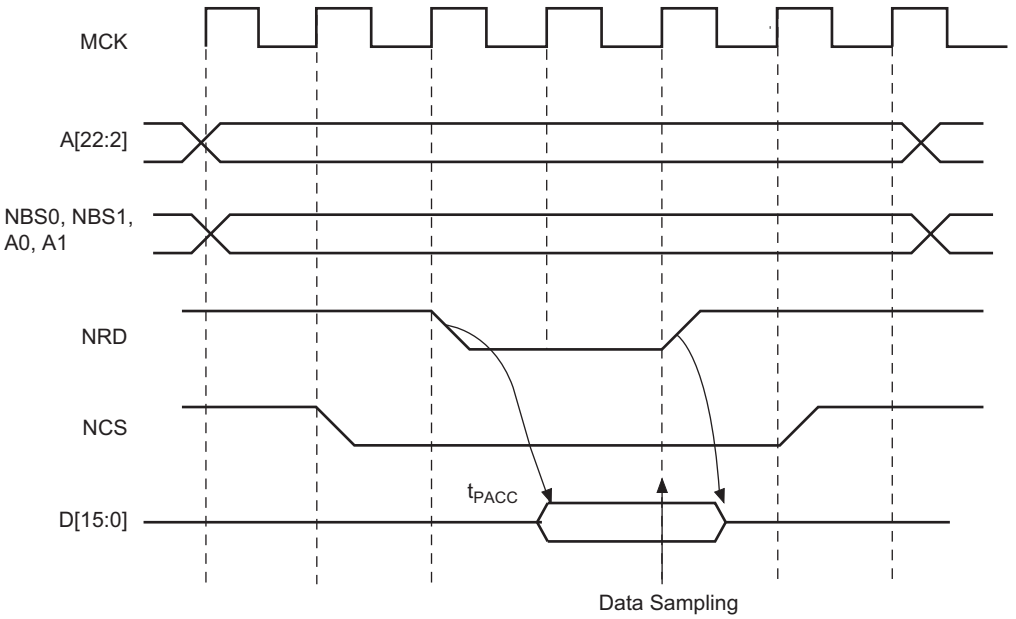
© 2026 Microchip Technology Inc. and its subsidiaries

Figure 20.7. No Setup, No Hold On NRD and NCS Read Signals

20.10.1.5.Null Pulse

Programming a null pulse is not permitted. Pulse must be at least set to 1. A null value leads to unpredictable behavior.

20.10.2. Read Mode



As NCS and NRD waveforms are defined independently of one other, the SMC needs to know when the read data is available on the data bus. The SMC does not compare NCS and NRD timings to know which signal rises first. The READ_MODE parameter in the SMC_MODE register of the corresponding chip select indicates which signal of NRD and NCS controls the read operation.

20.10.2.1.Read is Controlled by NRD (READ_MODE = 1)

The following figure shows the waveforms of a read operation of a typical asynchronous RAM. The read data is available t_{PACC} after the falling edge of NRD, and turns to 'Z' after the rising edge of NRD. In this case, the READ_MODE must be set to 1 (read is controlled by NRD), to indicate that data is available with the rising edge of NRD. The SMC samples the read data internally on the rising edge of the main system bus clock that generates the rising edge of NRD, regardless of the NCS programmed waveform.

© 2026 Microchip Technology Inc. and its subsidiaries

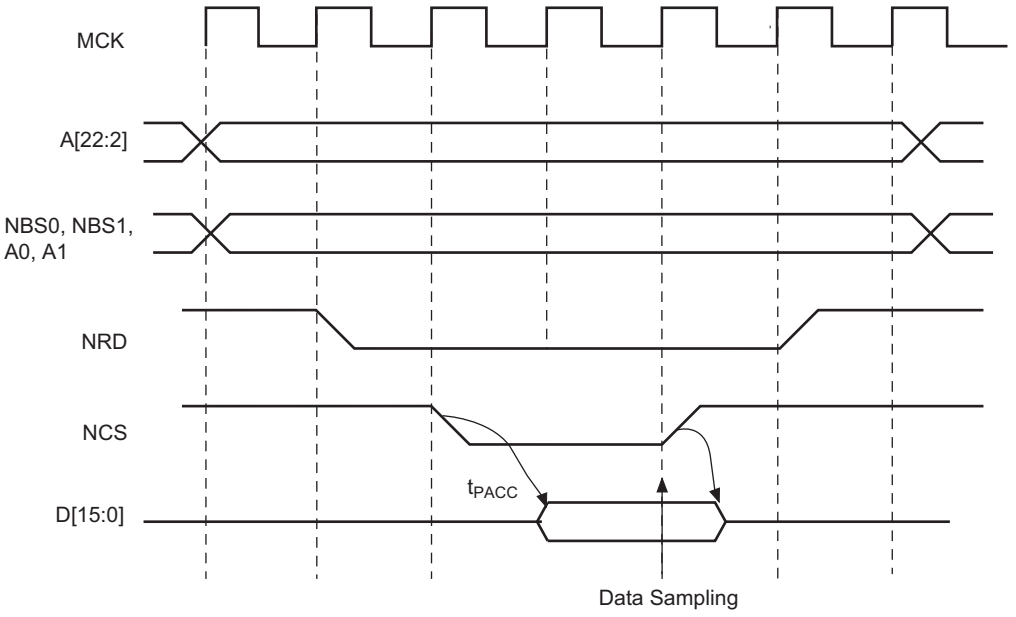


Figure 20.8. READ_MODE = 1 (Data sampled by SMC before rising edge of NRD)

20.10.2.2.Read is Controlled by NCS (READ_MODE = 0)

The following figure shows the typical read cycle of an LCD module. The read data is valid t_{PACC} after the falling edge of the NCS signal and remains valid until the rising edge of NCS. Data must be sampled when NCS is raised. In that case, READ_MODE must be set to 0 (read is controlled by NCS): the SMC internally samples the data on the rising edge of the main system bus clock that generates the rising edge of NCS, regardless of the NRD programmed waveform.

Figure 20.9. READ_MODE = 0 (Data sampled by SMC before rising edge of NCS)

20.10.3. Write Waveforms

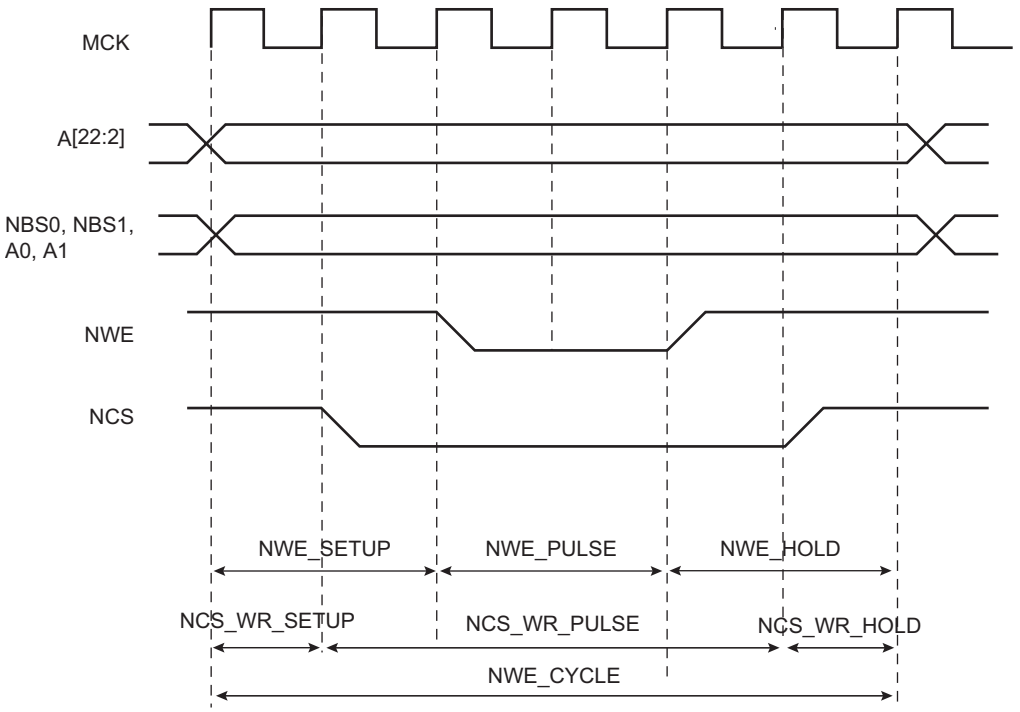
The write protocol (depicted in Figure 20.10) is similar to the read protocol. The write cycle starts with the address setting on the memory address bus.

© 2026 Microchip Technology Inc. and its subsidiaries

20.10.3.1.NWE Waveforms

The NWE signal is characterized by a setup timing, a pulse width and a hold timing.

- NWE_SETUP—NWE setup time is defined as the setup of address and data before the NWE falling edge.
- NWE_PULSE—NWE pulse length is the time between NWE falling edge and NWE rising edge.
- NWE_HOLD—NWE hold time is defined as the hold time of address and data after the NWE rising edge.



The NWE waveforms apply to all byte-write lines in Byte Write Access mode: NWR0 to NWR1.

20.10.3.2.NCS Waveforms

The NCS signal waveforms in write operations are not the same than those applied in read operations, but are defined separately:

- NCS_WR_SETUP—NCS setup time is defined as the setup time of address before the NCS falling edge.
- NCS_WR_PULSE—NCS pulse length is the time between NCS falling edge and NCS rising edge.
- NCS_WR_HOLD—NCS hold time is defined as the hold time of address after the NCS rising edge.

Figure 20.10. Write Cycle

20.10.3.3.Write Cycle

The write_cycle time is defined as the total duration of the write cycle, that is, from the time where address is set on the address bus to the point where address may change. The total write cycle time is defined as:

- NWE_CYCLE = NWE_SETUP + NWE_PULSE + NWE_HOLD

as well as

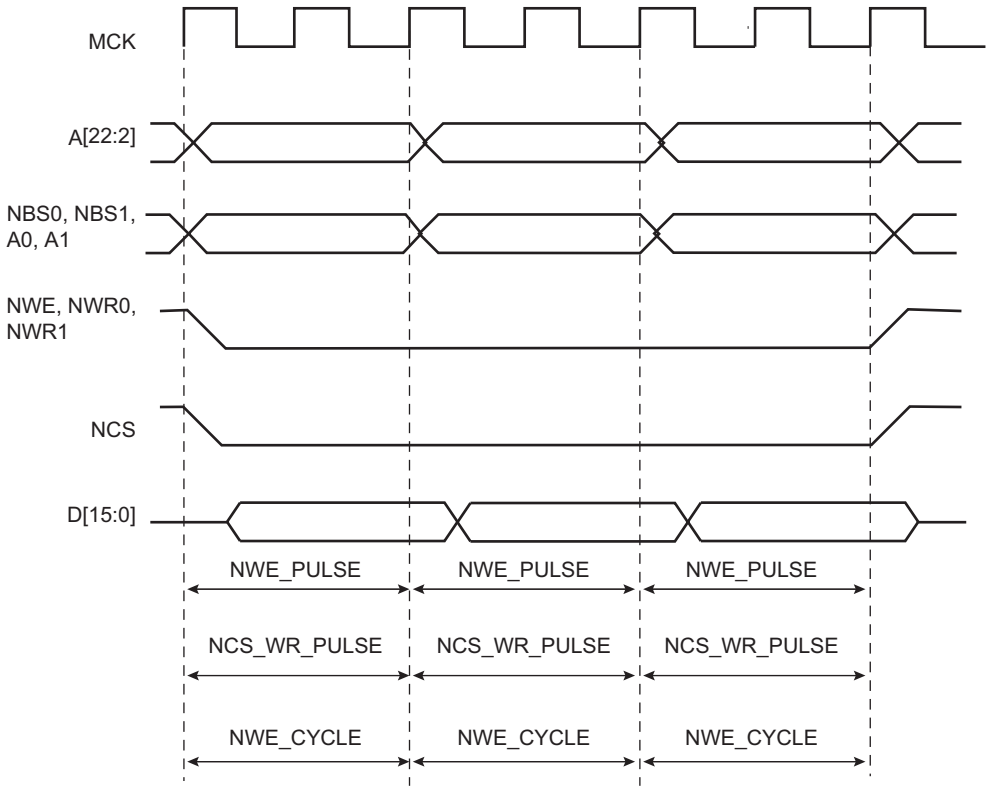
- NWE_CYCLE = NCS_WR_SETUP + NCS_WR_PULSE + NCS_WR_HOLD

© 2026 Microchip Technology Inc. and its subsidiaries

All NWE and NCS (write) timings are defined separately for each chip select as an integer number of the main system bus clock cycles. The NWE_CYCLE field is common to both the NWE and NCS signals, thus the timing period is of the same duration.

NWE_CYCLE, NWE_SETUP, and NWE_PULSE implicitly define the NWE_HOLD value as:

- NWE_HOLD = NWE_CYCLE - NWE_SETUP - NWE_PULSE



NWE_CYCLE, NCS_WR_SETUP, and NCS_WR_PULSE implicitly define the NCS_WR_HOLD value as:

- NCS_WR_HOLD = NWE_CYCLE - NCS_WR_SETUP - NCS_WR_PULSE

20.10.3.4.Null Delay Setup and Hold

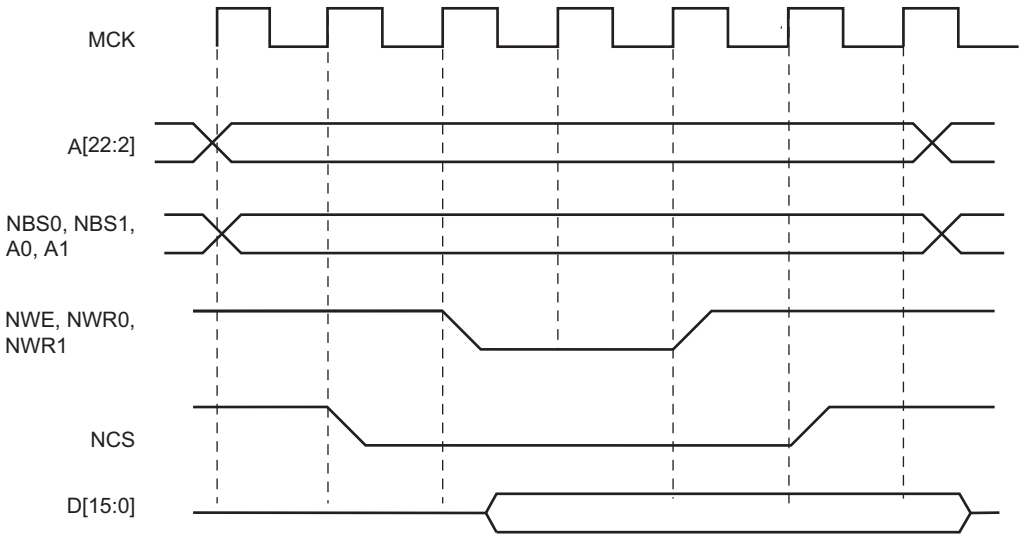
If null setup parameters are programmed for NWE and/or NCS, NWE and/or NCS remain active continuously in case of consecutive write cycles in the same memory. See the following figure. However, for devices that perform write operations on the rising edge of NWE or NCS, such as SRAM, either a setup or a hold must be programmed.

Figure 20.11. Null Setup and Hold Values of NCS and NWE in Write Cycle

20.10.3.5.Null Pulse

Programming a null pulse is not permitted. Pulse must be at least set to 1. A null value leads to unpredictable behavior.

20.10.4. Write Mode



The WRITE_MODE parameter in the SMC_MODE register of the corresponding chip select indicates which signal controls the write operation.

20.10.4.1.Write is Controlled by NWE (WRITE_MODE = 1)

The following figure shows the waveforms of a write operation with WRITE_MODE set to 1. The data is put on the bus during the pulse and hold steps of the NWE signal. The internal data buffers are switched to Output mode after the NWE_SETUP time, and until the end of the write cycle, regardless of the programmed waveform on NCS.

© 2026 Microchip Technology Inc. and its subsidiaries

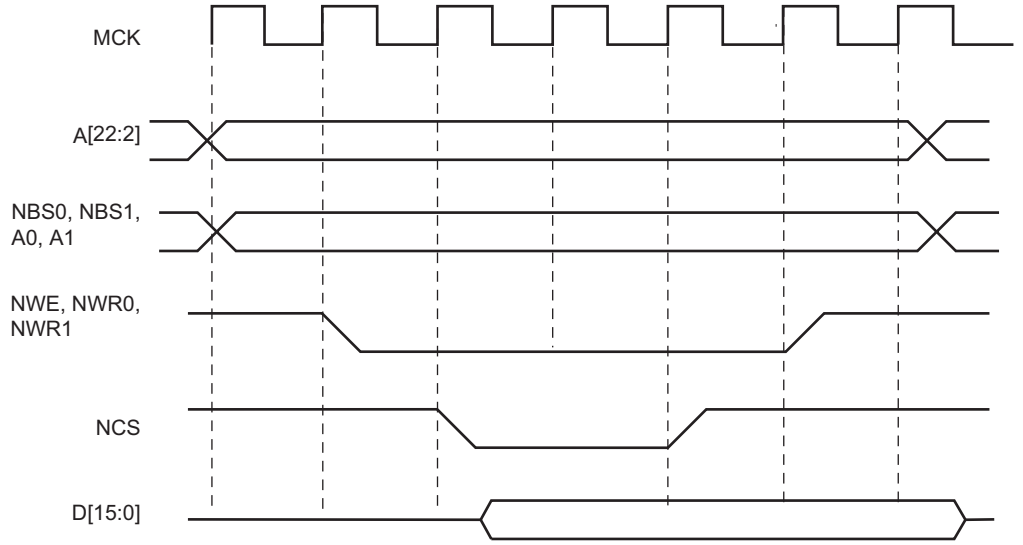


Figure 20.12. WRITE_MODE = 1 (Write Operation Controlled by NWE)

20.10.4.2.Write is Controlled by NCS (WRITE_MODE = 0)

The following figure shows the waveforms of a write operation with WRITE_MODE set to 0. The data is put on the bus during the pulse and hold steps of the NCS signal. The internal data buffers are switched to Output mode after the NCS_WR_SETUP time, and until the end of the write cycle, regardless of the programmed waveform on NWE.

Figure 20.13. WRITE_MODE = 0 (Write Operation Controlled by NCS)

20.10.5. Coding Timing Parameters

All timing parameters are defined for one chip select and are grouped together in one SMC_REGISTER according to their type.

The SMC_SETUP register groups the definition of all setup parameters:

- NRD_SETUP, NCS_RD_SETUP, NWE_SETUP, NCS_WR_SETUP

The SMC_PULSE register groups the definition of all pulse parameters:

- NRD_PULSE, NCS_RD_PULSE, NWE_PULSE, NCS_WR_PULSE

© 2026 Microchip Technology Inc. and its subsidiaries

The SMC_CYCLE register groups the definition of all cycle parameters:

- NRD_CYCLE, NWE_CYCLE

The following table shows how the timing parameters are coded and their permitted range.

Table 20.4. Coding and Range of Timing Parameters

Coded Value	Number of Bits	Effective Value	Permitted Range	
			Coded Value	Effective Value
setup [5:0]	6	128 x setup[5] + setup[4:0]	0 ≤ 31	0 ≤ 128 + 31
pulse [6:0]	7	256 x pulse[6] + pulse[5:0]	0 ≤ 63	0 ≤ 256 + 63
cycle [8:0]	9	256 x cycle[8:7] + cycle[6:0]	0 ≤ 127	0 ≤ 256 + 127 0 ≤ 512 +1 27 0 ≤ 768 + 127

20.10.6. Reset Values of Timing Parameters

For the default values of timing parameters at reset, see SMC_SETUPx, SMC_PULSEx and SMC_CYCLEx.

20.10.7. Usage Restriction

The SMC does not check the validity of the user-programmed parameters. If the sum of SETUP and PULSE parameters is larger than the corresponding CYCLE parameter, this leads to unpredictable behavior of the SMC.

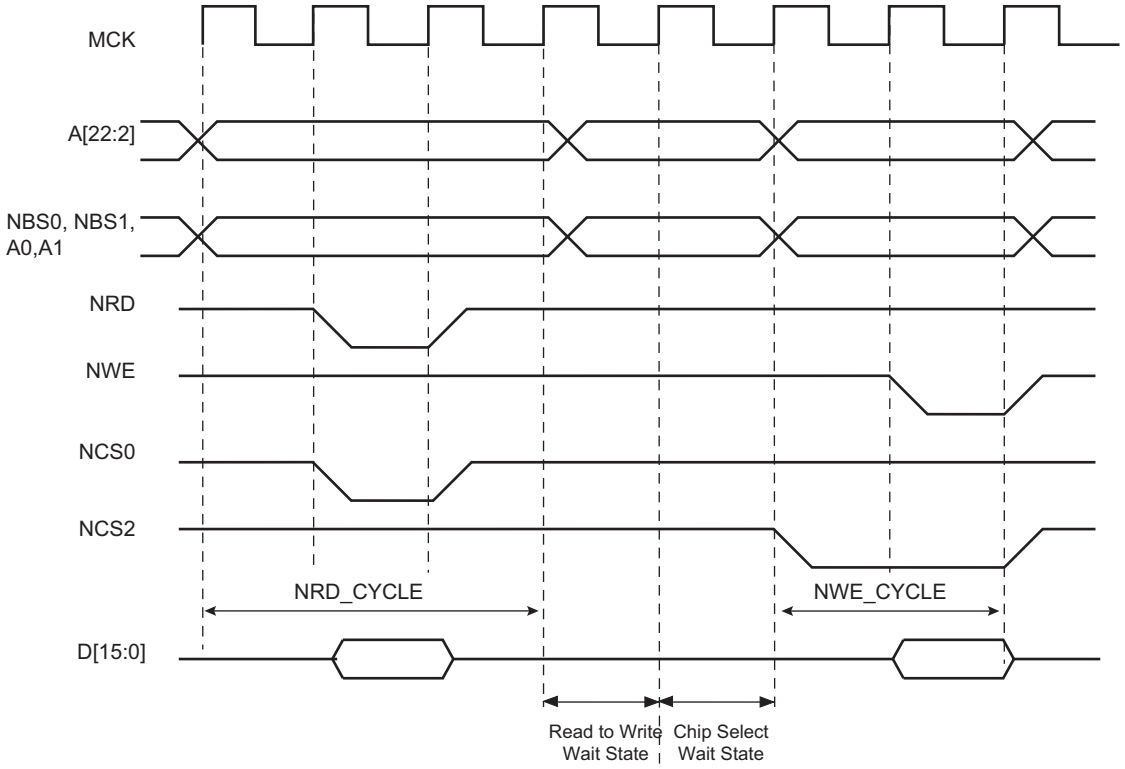
- For read operations:
  Null but positive setup and hold of address and NRD and/or NCS can not be guaranteed at the memory interface because of the propagation delay of theses signals through external logic and pads. If positive setup and hold values must be verified, then it is strictly recommended to program non-null values so as to cover possible skews between address, NCS and NRD signals.
- For write operations:
  If a null hold value is programmed on NWE, the SMC can guarantee a positive hold of address, byte select lines, and NCS signal after the rising edge of NWE. This is true for WRITE_MODE = 1 only. See Early Read Wait State.
- For read and write operations:
  A null value for pulse parameters is forbidden and may lead to unpredictable behavior.

  In read and write cycles, the setup and hold time parameters are defined in reference to the address bus. For external devices that require setup and hold time between NCS and NRD signals (read), or between NCS and NWE signals (write), these setup and hold times must be converted into setup and hold times in reference to the address bus.

20.11. Automatic Wait States

Under certain circumstances, the SMC automatically inserts idle cycles between accesses to avoid bus contention or operation conflict.

20.11.1. Chip Select Wait States



The SMC always inserts an idle cycle between two transfers on separate chip selects. This idle cycle ensures that there is no bus contention between the de-activation of one device and the activation of the next one.

During Chip Select Wait state, all control lines are turned inactive: NBS0 to NBS1, NWR0 to NWR1, NCS[0..2], NRD lines are all set to 1.

The following figure illustrates a Chip Select Wait state between accesses on Chip Select 0 and Chip Select 2.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 20.14. Chip Select Wait State between a Read Access on NCS0 and a Write Access on NCS2

20.11.2. Early Read Wait State

In some cases, the SMC inserts a Wait state cycle between a write access and a read access to allow time for the write cycle to end before the subsequent read cycle begins. This Wait state is not generated in addition to a Chip Select Wait state. The early read cycle thus only occurs between a write and read access to the same memory device (same chip select).

An Early Read Wait state is automatically inserted if at least one of the following conditions is valid:

- The write controlling signal has no hold time and the read controlling signal has no setup time (Figure 20.15).
- In NCS Write Controlled mode (WRITE_MODE = 0), there is no hold timing on the NCS signal and the NCS_RD_SETUP parameter is set to 0, regardless of the read mode (Figure 20.16). The write operation must end with a NCS rising edge. Without an Early Read Wait State, the write operation could not complete properly.
- In NWE Controlled mode (WRITE_MODE = 1) and if there is no hold timing (NWE_HOLD = 0), the feedback of the write control signal is used to control address, data, chip select and byte select lines. If the external write control signal is not inactivated as expected due to load capacitances, an Early Read Wait State is inserted and address, data and control signals are maintained one more cycle. See Figure 20.17.

Figure 20.17. Early Read Wait State: NWE-controlled Write with No Hold Followed by a Read with one Set-up Cycle

20.11.3. Reload User Configuration Wait State

The user may change any of the configuration parameters by writing the SMC user interface.

When detecting that a new user configuration has been written in the user interface, the SMC inserts a wait state before starting the next access. The so called “Reload User Configuration Wait State” is used by the SMC to load the new set of parameters to apply to next accesses.

The Reload Configuration Wait State is not applied in addition to the Chip Select Wait State. If accesses before and after re-programming the user interface are made to different devices (Chip Selects), then one single Chip Select Wait State is applied.

On the other hand, if accesses before and after writing the user interface are made to the same device, a Reload Configuration Wait State is inserted, even if the change does not concern the current Chip Select.

20.11.3.1. User Procedure

To insert a Reload Configuration Wait State, the SMC detects a write access to any SMC_MODE register of the user interface. If the user only modifies timing registers (SMC_SETUP, SMC_PULSE, SMC_CYCLE registers) in the user interface, he must validate the modification by writing the SMC_MODE, even if no change was made on the mode parameters.

The user must not change the configuration parameters of an SMC Chip Select (Setup, Pulse, Cycle, Mode) if accesses are performed on this CS during the modification. Any change of the Chip Select parameters, while fetching the code from a memory connected on this CS, may lead to unpredictable behavior. The instructions used to modify the parameters of an SMC Chip Select can be executed from the internal RAM or from a memory connected to another CS.

20.11.3.2. Slow Clock Mode Transition

A Reload Configuration Wait state is also inserted when the Slow Clock mode is entered or exited, after the end of the current transfer (see Slow Clock Mode).

© 2026 Microchip Technology Inc. and its subsidiaries

20.11.4. Read to Write Wait State

Due to an internal mechanism, a wait cycle is always inserted between consecutive read and write SMC accesses.

This wait cycle is referred to as a Read to Write Wait state in this document.

This wait cycle is applied in addition to chip select and reload user configuration Wait states when they are to be inserted. See Figure 20.14.

20.12. Data Float Wait States

Some memory devices are slow to release the external bus. For such devices, it is necessary to add wait states (data float wait states) after a read access:

- before starting a read access to a different external memory
- before starting a write access to the same device or to a different external one.

The Data Float Output Time (t_{DF}) for each external memory device is programmed in the TDF_CYCLES field of the SMC_MODE register for the corresponding chip select. The value of TDF_CYCLES indicates the number of data float wait cycles (between 0 and 15) before the external device releases the bus, and represents the time allowed for the data output to go to high impedance after the memory is disabled.

Data float wait states do not delay internal memory accesses. Hence, a single access to an external memory with long t_{DF} will not slow down the execution of a program from internal memory.

The data float wait states management depends on the READ_MODE and the TDF_MODE fields of the SMC_MODE register for the corresponding chip select.

20.12.1. READ_MODE

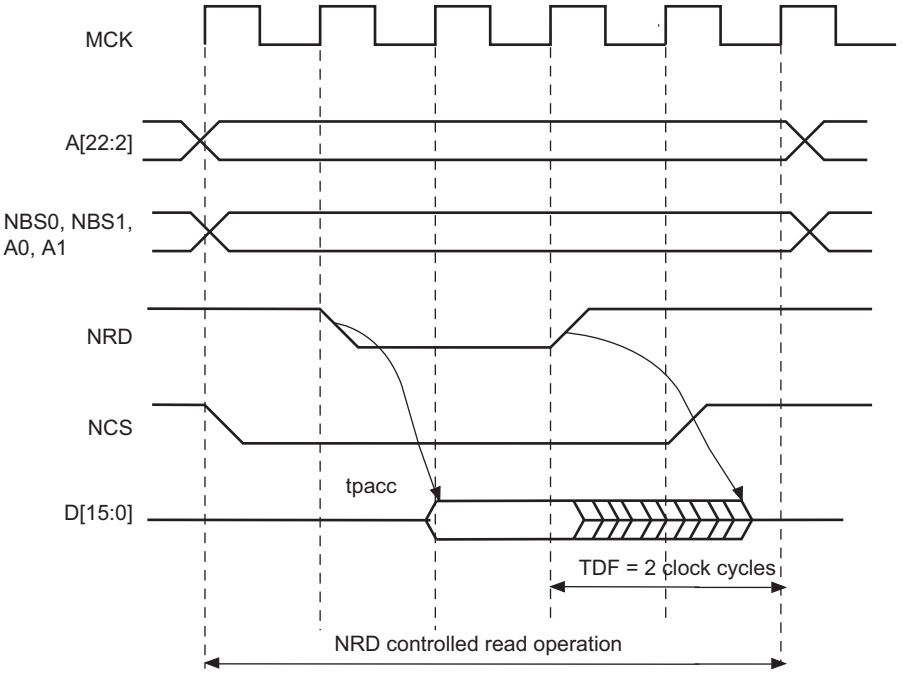
Setting READ_MODE to 1 indicates to the SMC that the NRD signal is responsible for turning off the tri-state buffers of the external memory device. The Data Float Period then begins after the rising edge of the NRD signal and lasts TDF_CYCLES MCK cycles.

When the read operation is controlled by the NCS signal (READ_MODE = 0), the TDF field shows the number of MCK cycles during which the data bus remains busy after the rising edge of NCS.

Figure 20.18 illustrates the Data Float Period in NRD-controlled mode (READ_MODE = 1), assuming a data float period of two cycles (TDF_CYCLES = 2). Figure 20.19 shows the read operation when controlled by NCS (READ_MODE = 0) and the TDF_CYCLES parameter equals 3.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 20.18. TDF Period in NRD Controlled Read Access (TDF = 2)



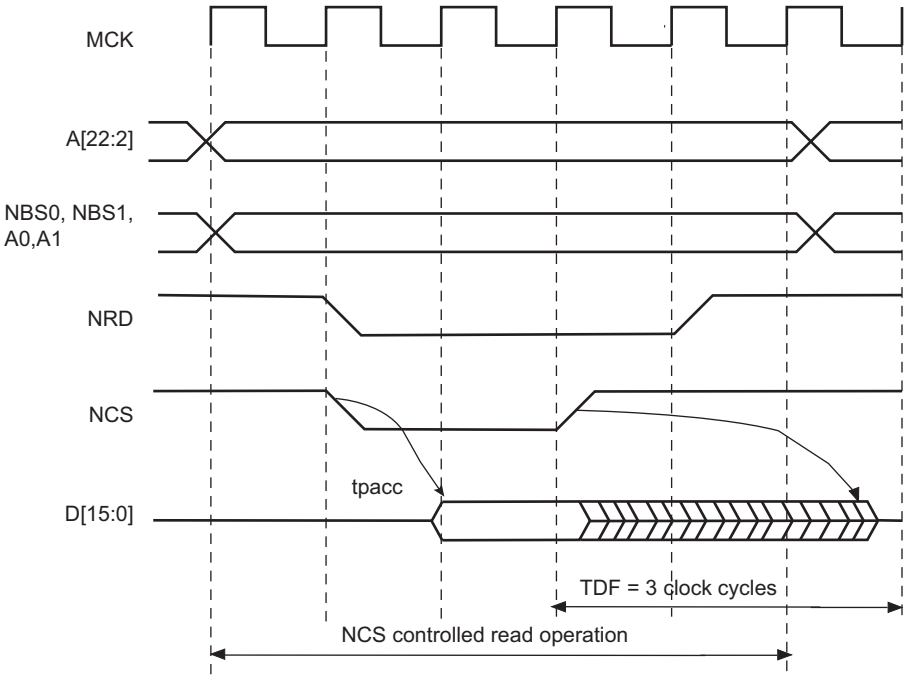


Figure 20.19. TDF Period in NCS Controlled Read Operation (TDF = 3)

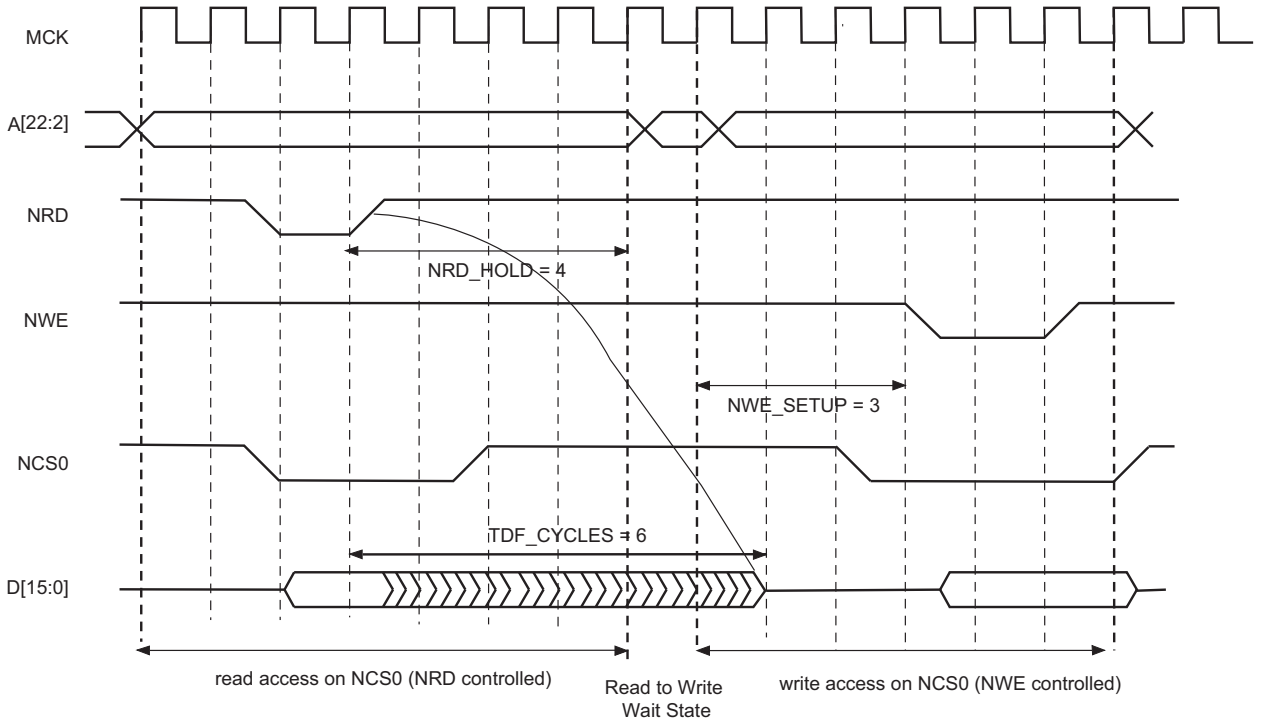
20.12.2. TDF Optimization Enabled (TDF_MODE = 1)

When SMC_MODE.TDF_MODE is set to 1 (TDF optimization enabled), the SMC takes advantage of the setup period of the next access to optimize the number of Wait state cycles to insert.

The following figure shows a read access controlled by NRD, followed by a write access controlled by NWE, on Chip Select 0. Chip Select 0 has been programmed with:



NRD_HOLD = 4; READ_MODE = 1 (NRD controlled)

© 2026 Microchip Technology Inc. and its subsidiaries

NWE_SETUP = 3; WRITE_MODE = 1 (NWE controlled)

TDF_CYCLES = 6; TDF_MODE = 1 (optimization enabled).

Figure 20.20. TDF Optimization: No TDF Wait states are inserted if the TDF period is over when the next access begins

20.12.3. TDF Optimization Disabled (TDF_MODE = 0)

When optimization is disabled, TDF Wait states are inserted at the end of the read transfer, so that the data float period is ended when the second access begins. If the hold period of the read1 controlling signal overlaps the data float period, no additional TDF Wait states will be inserted.

Figure 20.21, Figure 20.22 and Figure 20.23 illustrate the following cases, with no TDF optimization:

- Read access followed by a read access on another chip select
- Read access followed by a write access on another chip select
- Read access followed by a write access on the same chip select

© 2026 Microchip Technology Inc. and its subsidiaries

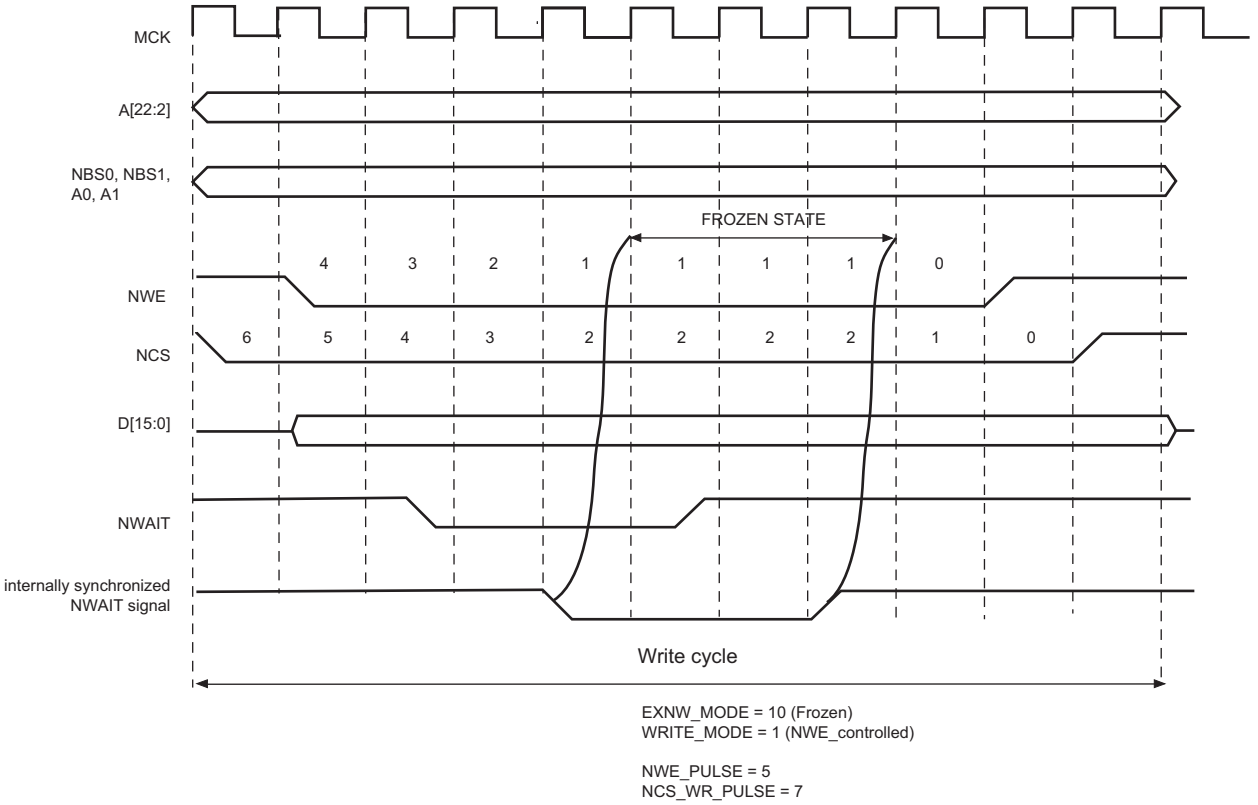
Figure 20.23. TDF Mode = 0: TDF Wait states between read and write accesses on the same chip select

20.13. External Wait

Any access can be extended by an external device using the NWAIT input signal of the SMC. The EXNW_MODE field of the SMC_MODE register on the corresponding chip select must be set to either to '10' (Frozen mode) or '11' (Ready mode). When the EXNW_MODE is set to '00' (disabled), the NWAIT signal is simply ignored on the corresponding chip select. The NWAIT signal delays the read or write operation as regards the read or write controlling signal, depending on the read and write modes of the corresponding chip select.

20.13.1. Restriction

When one of the EXNW_MODE is enabled, at least one hold cycle must be programmed for the read/write controlling signal. For that reason, the NWAIT signal cannot be used in Page mode (see Asynchronous Page Mode) nor in Slow Clock mode (see Slow Clock Mode).



The NWAIT signal is assumed to be a response of the external device to the read/write request of the SMC. Then NWAIT is examined by the SMC only in the Pulse state of the read or write controlling signal. The assertion of the NWAIT signal outside the expected period has no impact on SMC behavior.

20.13.2. Frozen Mode

When the external device asserts the NWAIT signal (active low), and after internal synchronization of this signal, the SMC state is frozen, i.e., SMC internal counters are frozen, and all control signals remain unchanged. When the resynchronized NWAIT signal is deasserted, the SMC completes the access, resuming the access from the point where it was stopped. See the following figure. This mode must be selected when the external device uses the NWAIT signal to delay the access and to freeze the SMC.

© 2026 Microchip Technology Inc. and its subsidiaries

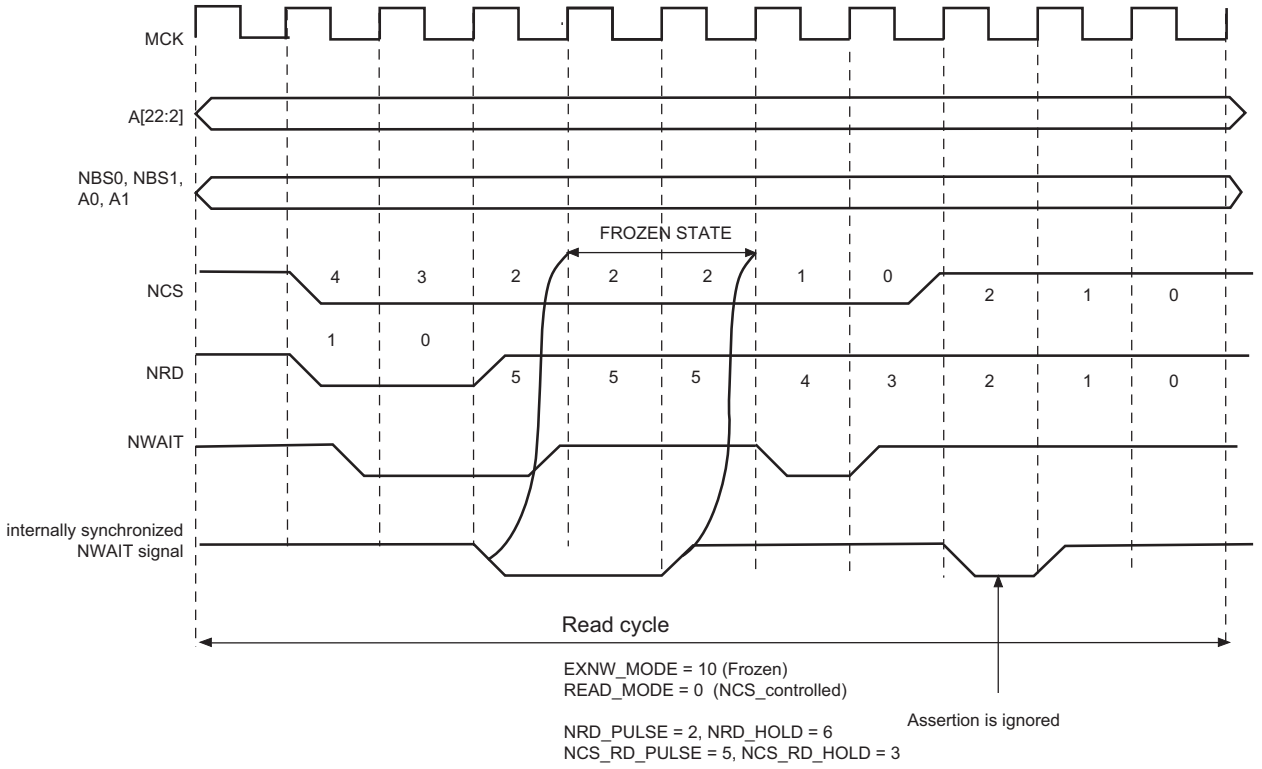


Figure 20.24. Write Access with NWAIT Assertion in Frozen Mode (EXNW_MODE = 10)

The assertion of the NWAIT signal outside the expected period is ignored as illustrated in the figure below.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 20.25. Read Access with NWAIT Assertion in Frozen Mode (EXNW_MODE = 10)

20.13.3. Ready Mode

In Ready mode (EXNW_MODE = 11), the SMC behaves differently. Normally, the SMC begins the access by down counting the setup and pulse counters of the read/write controlling signal. In the last cycle of the pulse phase, the resynchronized NWAIT signal is examined.

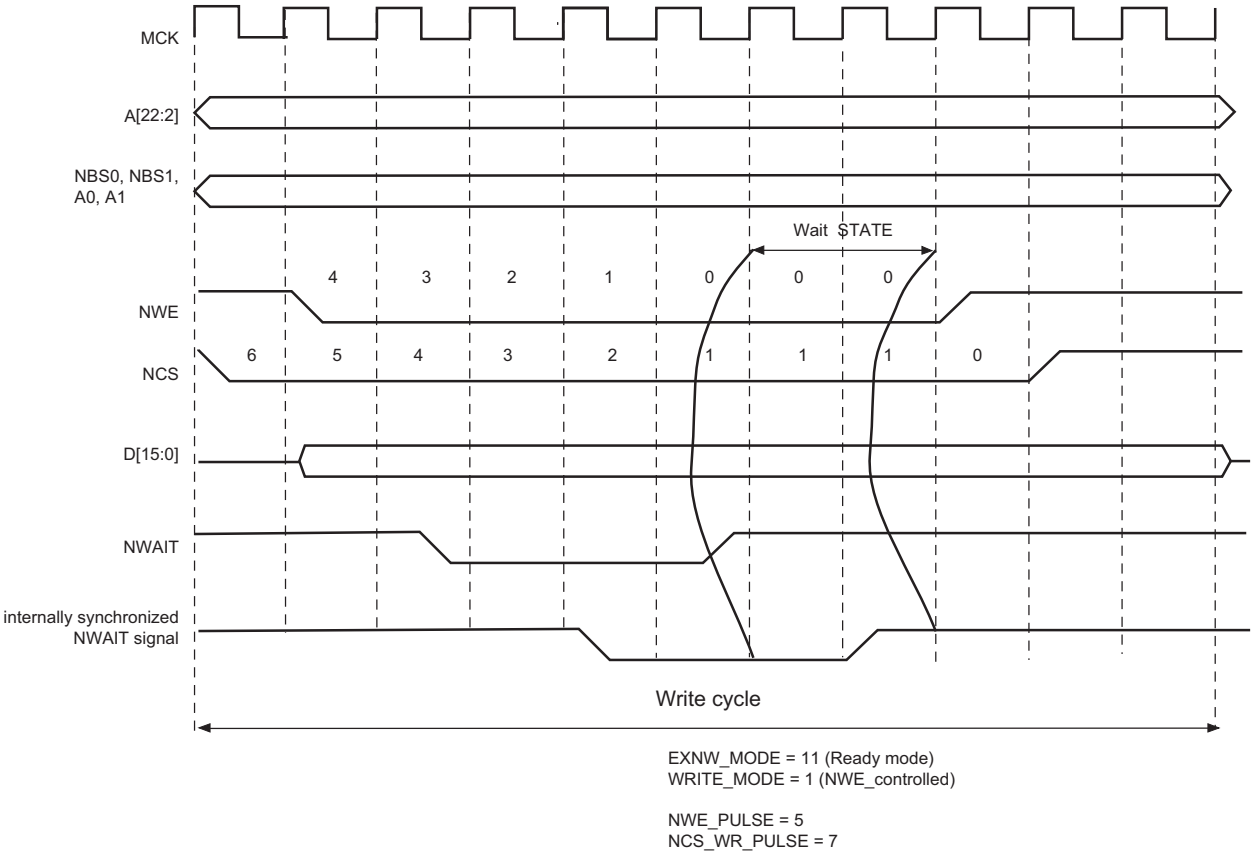
If asserted, the SMC suspends the access as shown in the figures Figure 20.26 and Figure 20.27. After deassertion, the access is completed: the hold step of the access is performed.

This mode must be selected when the external device uses deassertion of the NWAIT signal to indicate its ability to complete the read or write operation.

If the NWAIT signal is deasserted before the end of the pulse, or asserted after the end of the pulse of the controlling read/write signal, it has no impact on the access length as shown in Figure 20.27.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 20.26. NWAIT Assertion in Write Access: Ready Mode (EXNW_MODE = 11)



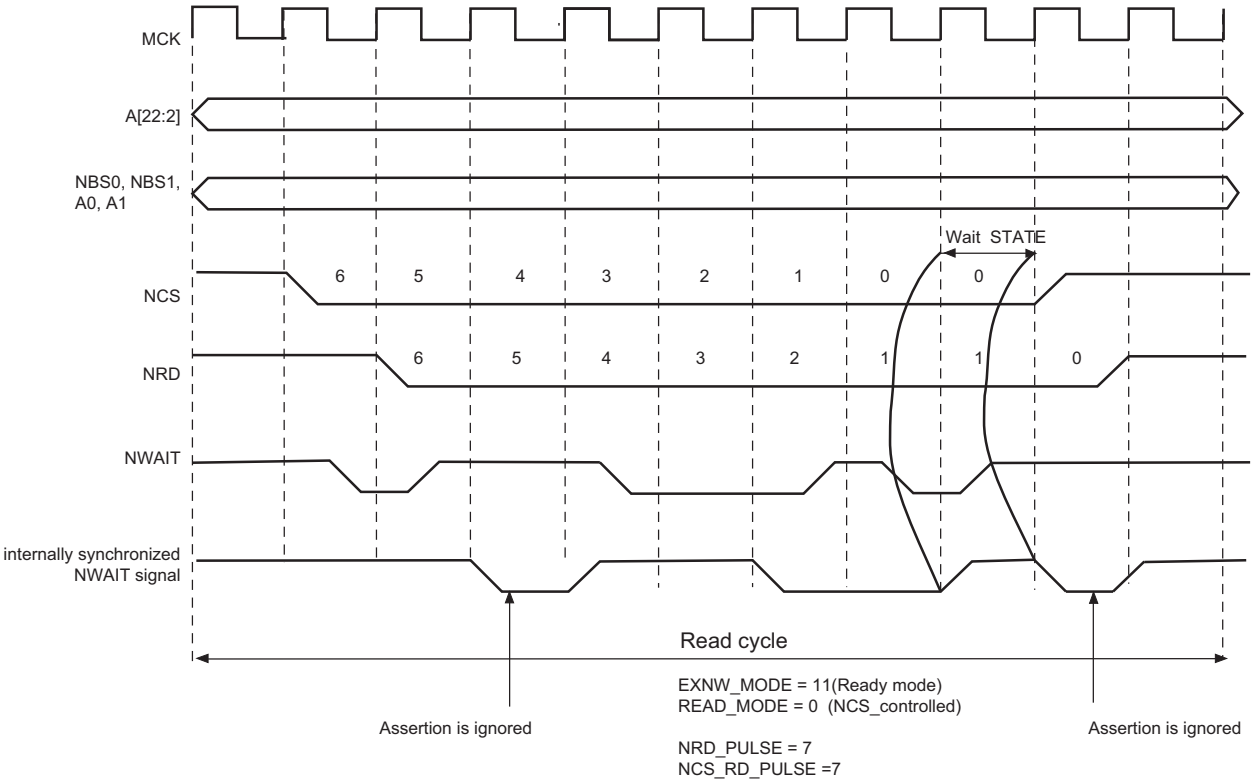


Figure 20.27. NWAIT Assertion in Read Access: Ready Mode (EXNW_MODE = 11)

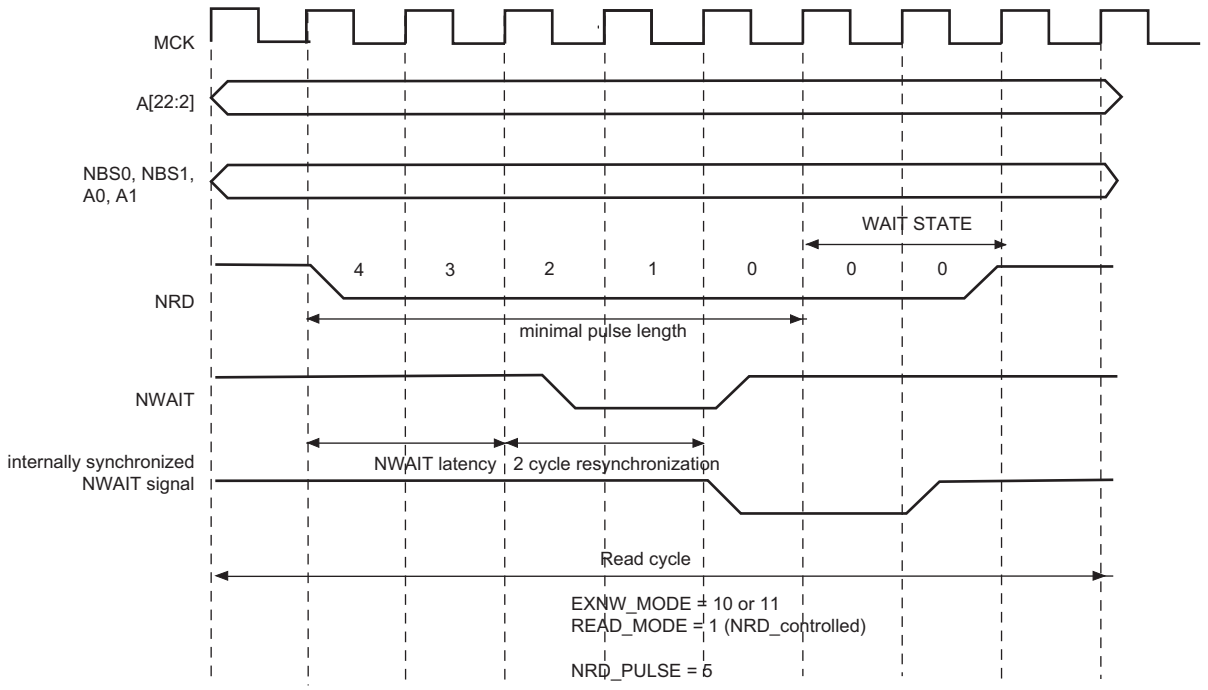
© 2026 Microchip Technology Inc. and its subsidiaries



20.13.4. NWAIT Latency and Read/Write Timings

There may be a latency between the assertion of the read/write controlling signal and the assertion of the NWAIT signal by the device. The programmed pulse length of the read/write controlling signal must be at least equal to this latency plus the 2 resynchronization cycles + 1 cycle. Otherwise, the SMC may enter the Hold state of the access without detecting the NWAIT signal assertion. This is true in Frozen mode as well as in Ready mode. This is illustrated in the following figure.

When EXNW_MODE is enabled (Ready or Frozen), the user must program a pulse length of the read and write controlling signal of at least:

minimal pulse length = NWAIT latency + 2 resynchronization cycles + 1 cycle

Figure 20.28. NWAIT Latency

20.14. Slow Clock Mode

The SMC is able to automatically apply a set of “Slow Clock mode” read/write waveforms when an internal signal driven by the Power Management Controller is asserted because MCK has been configured to a very slow clock rate (typically, 32 kHz). In this mode, the user-programmed waveforms are ignored and the Slow Clock mode waveforms are applied. This mode is provided to avoid reprogramming the User Interface with appropriate waveforms at very slow clock rates. When activated, Slow Clock mode is active on all chip selects.

20.14.1. Slow Clock Mode Waveforms

The figure below illustrates the read and write operations in Slow Clock mode. They are valid on all chip selects. The following table indicates the value of read and write parameters in Slow Clock mode.

Figure 20.29. Read/Write Cycles in Slow Clock Mode

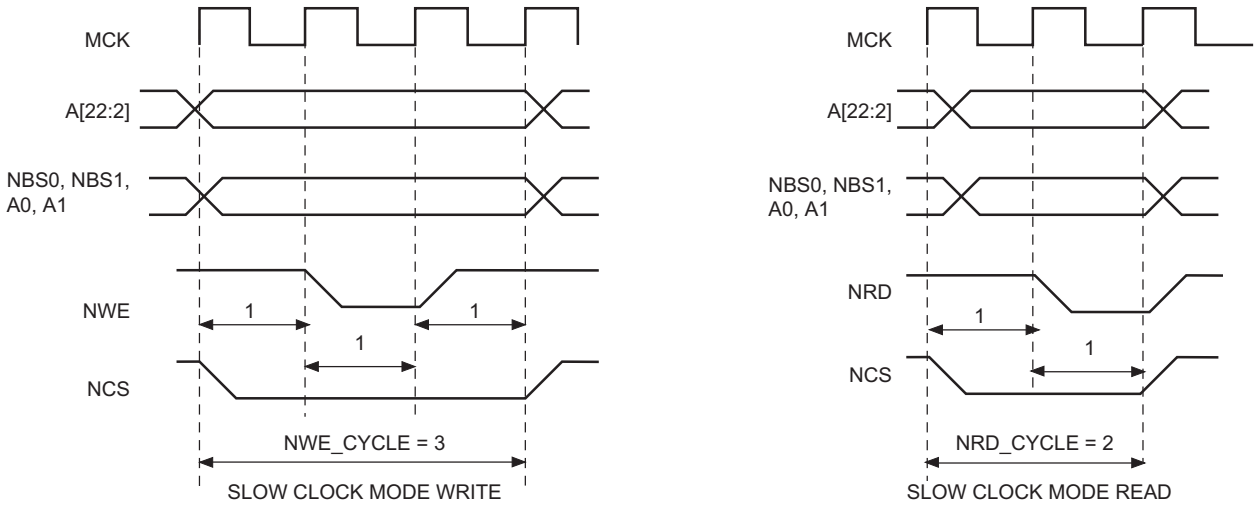

Table 20.5. Read and Write Timing Parameters in Slow Clock Mode

Read Parameters	Duration (cycles)	Write Parameters	Duration (cycles)
NRD_SETUP	1	NWE_SETUP	1
NRD_PULSE	1	NWE_PULSE	1
NCS_RD_SETUP	0	NCS_WR_SETUP	0
NCS_RD_PULSE	2	NCS_WR_PULSE	3
NRD_CYCLE	2	NWE_CYCLE	3

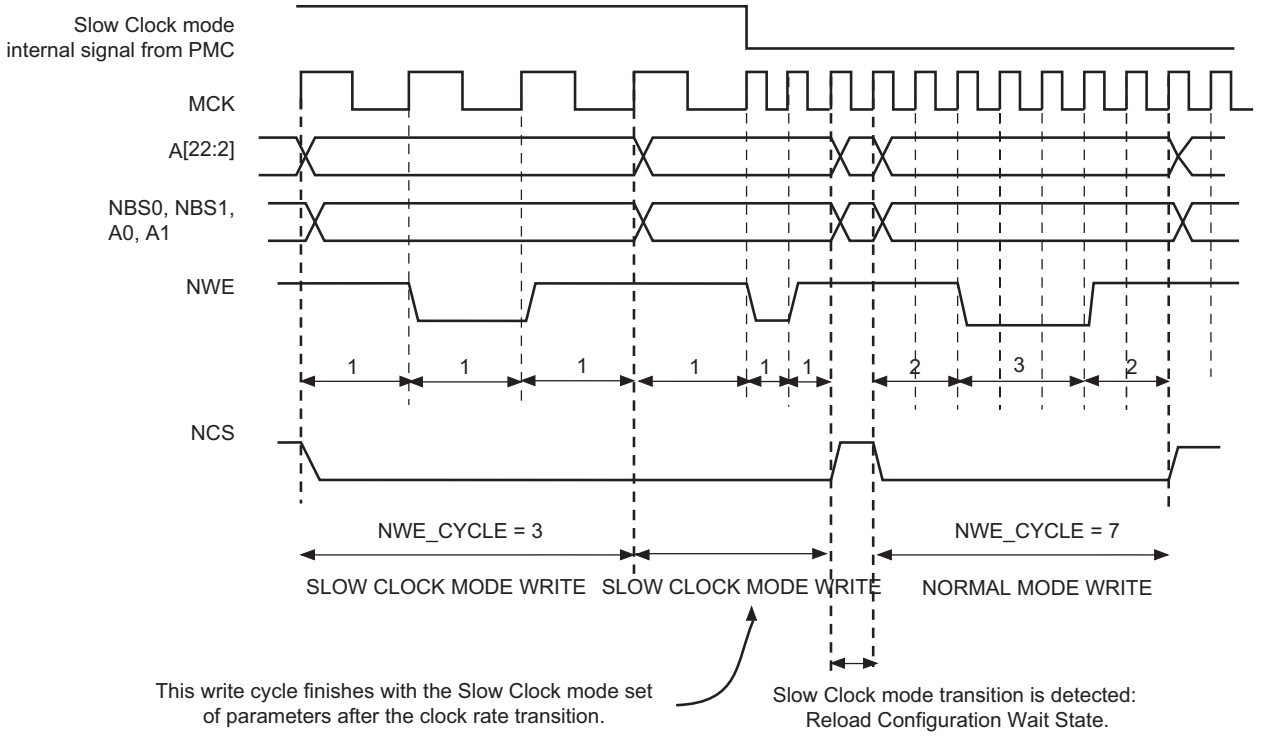
20.14.2. Switching from (to) Slow Clock Mode to (from) Normal Mode

When switching from Slow Clock mode to Normal mode, the current Slow Clock mode transfer is completed at high clock rate, with the set of Slow Clock mode parameters. See Figure 20.30. The external device may not be fast enough to support such timings.

Figure 20.31 illustrates the recommended procedure to properly switch from one mode to the other.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 20.30. Clock Rate Transition Occurs while the SMC is Performing a Write Operation



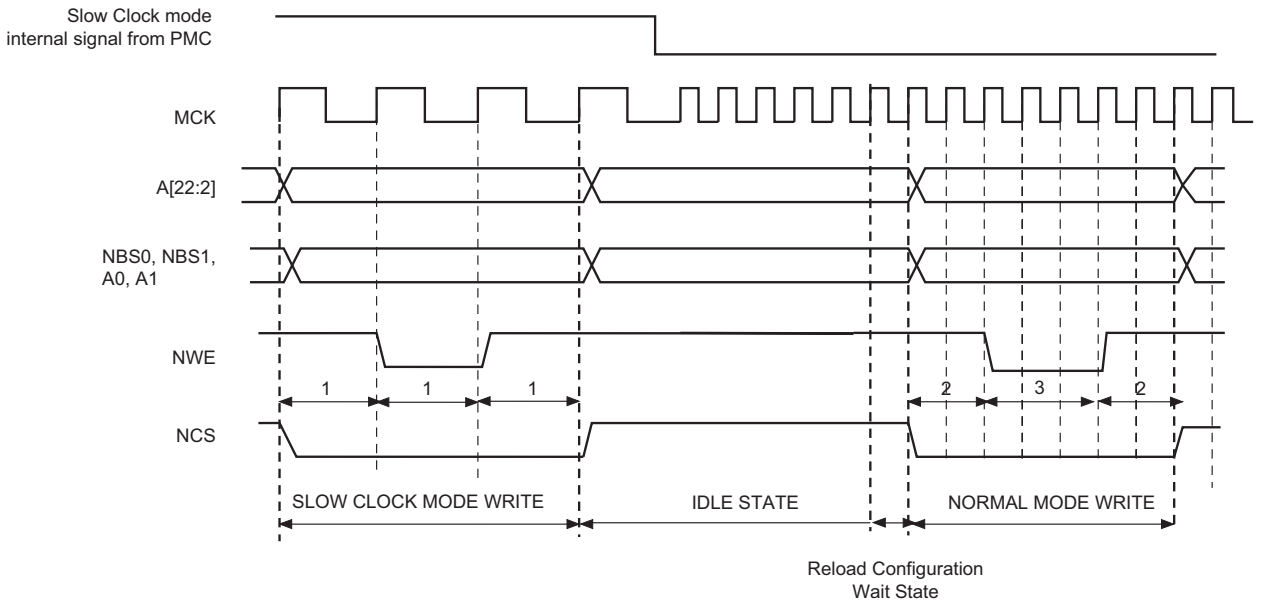


Figure 20.31. Recommended Procedure to Switch from Slow Clock Mode to Normal Mode or from Normal Mode to Slow Clock Mode

20.15. Asynchronous Page Mode

The SMC supports asynchronous burst reads in Page mode, providing that the Page mode is enabled in the SMC_MODE register (PMEN field). The page size must be configured in the SMC_MODE register (PS field) to 4, 8, 16 or 32 bytes.

The page defines a set of consecutive bytes into memory. A 4-byte page (resp. 8-, 16-, 32-byte page) is always aligned to 4-byte boundaries (resp. 8-, 16-, 32-byte boundaries) of memory. The MSB of

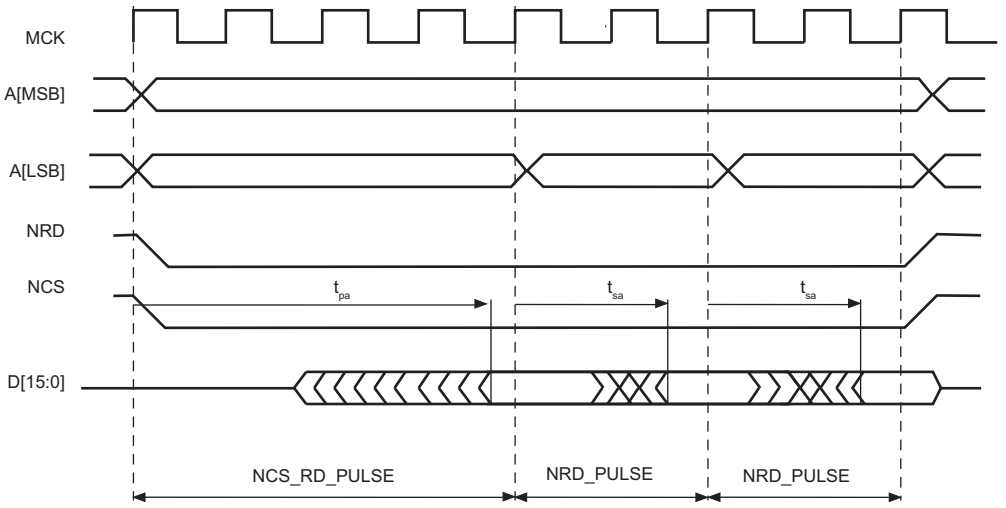
© 2026 Microchip Technology Inc. and its subsidiaries

data address defines the address of the page in memory, the LSB of address define the address of the data in the page as detailed in the table below.

With Page mode memory devices, the first access to one page (t_{pa}) takes longer than the subsequent accesses to the page (t_{sa}) as shown in Figure 20.32. When in Page mode, the SMC enables the user to define different read timings for the first access within one page, and next accesses within the page.

Table 20.6. Page Address and Data Address Within a Page

Page Size	Page Address (1)	Data Address in the Page (2)
4 bytes	A[22:2]	A[1:0]
8 bytes	A[22:3]	A[2:0]
16 bytes	A[22:4]	A[3:0]
32 bytes	A[22:5]	A[4:0]



Notes:

1. 'A' denotes the address bus of the memory device.
2. For 16-bit devices, bit 0 of the address is ignored.

20.15.1. Protocol and Timings in Page Mode

The following figure shows the NRD and NCS timings in Page mode access. For the address MSB and LSB, see Table 20.6.

Figure 20.32. Page Mode Read Protocol

The NRD and NCS signals are held low during all read transfers, whatever the programmed values of the setup and hold timings in the User Interface may be. Moreover, the NRD and NCS timings are identical. The pulse length of the first access to the page is defined with the NCS_RD_PULSE field of the SMC_PULSE register. The pulse length of subsequent accesses within the page are defined using the NRD_PULSE parameter.

Programming of the read timings in Page mode is described in the following table.

Table 20.7. Programming of Read Timings in Page Mode

Parameter	Value	Definition
READ_MODE	'x'	No impact
NCS_RD_SETUP	'x'	No impact
NCS_RD_PULSE	t_{pa}	Access time of first access to the page

© 2026 Microchip Technology Inc. and its subsidiaries

Table 20.7. Programming of Read Timings in Page Mode (continued)

Parameter	Value	Definition
NRD_SETUP	'x'	No impact
NRD_PULSE	t_{sa}	Access time of subsequent accesses in the page
NRD_CYCLE	'x'	No impact

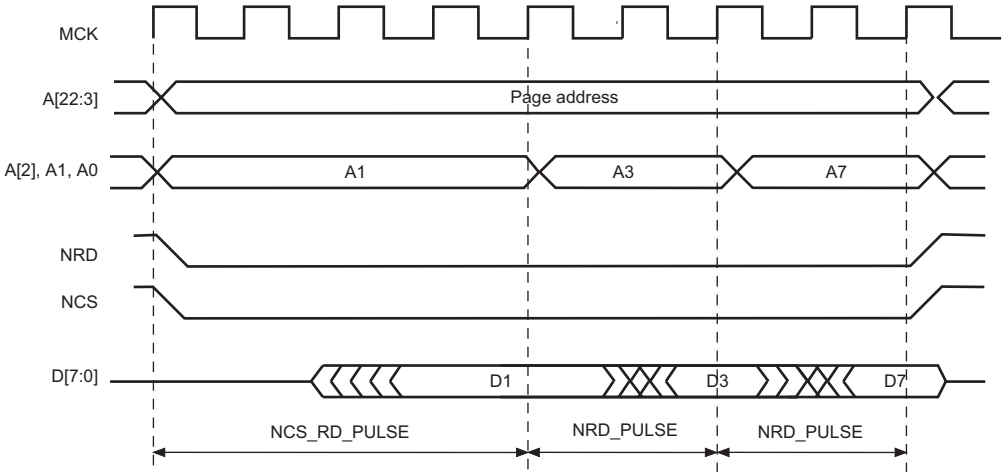
The SMC does not check the coherency of timings. It will always apply the NCS_RD_PULSE timings as page access timing (t_{pa}) and the NRD_PULSE for accesses to the page (t_{sa}), even if the programmed value for t_{pa} is shorter than the programmed value for t_{sa}.

20.15.2. Byte Access Type in Page Mode

The byte access type (BAT) configuration remains active in Page mode. For 16-bit Page mode devices that require byte selection signals, write a 0 to the BAT bit in the SMC Mode register (SMC_MODE) to select the byte select access type.

20.15.3. Page Mode Restriction

The Page mode is not compatible with the use of the NWAIT signal. Using the Page mode and the NWAIT signal may lead to unpredictable behavior.



20.15.4. Sequential and Non-Sequential Accesses

If the chip select and the MSB of addresses as defined in Table 20.6 are identical, then the current access lies in the same page as the previous one, and no page break occurs.

Using this information, all data within the same page, sequential or not sequential, are accessed with a minimum access time (t_{sa}). The following figure illustrates access to an 8-bit memory device in Page mode, with 8-byte pages. Access to D1 causes a page access with a long access time (t_{pa}). Accesses to D3 and D7, though they are not sequential accesses, only require a short access time (t_{sa}).

If the address MSBs differ, the SMC performs the access of a new page. In the same way, if the chip select is different from the previous access, a page break occurs. If two sequential accesses are made to the Page mode memory, but separated by an other internal or external peripheral access, a page break occurs on the second access because the chip select of the device was deasserted between both accesses.

Figure 20.33. Access to Non-sequential Data within the Same Page

© 2026 Microchip Technology Inc. and its subsidiaries

20.16. Register Write Protection

To prevent any single software error from corrupting SMC behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the Write Protection Mode Register (SMC_WPMR).

If a write access to a write-protected register is detected, the WPVS flag in the Write Protection Status Register (SMC_WPSR) is set and the field WPVSRC indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading SMC_WPSR.

The following registers can be write-protected:

- SMC Setup Register
- SMC Pulse Register
- SMC Cycle Register
- SMC Mode Register
- SMC Off-Chip Memory Scrambling Register
- SMC Safety Report Interrupt Enable Register

20.17. Security and Safety Analysis and Reports

Several types of checks are performed when the SMC is reading or writing an external memory.

The internal sequencer of the SMC is monitored for integrity and if an abnormal state is detected, the flag SMC_WPSR.SEQE is set. This flag is not set under normal operating conditions.

The software accesses to the SMC are monitored and if an incorrect access is performed, the flag SMC_WPSR.SWE is set. The type of incorrect/abnormal software access is reported in the SMC_WPSR.SWETYP field (see SMC Write Protection Status Register for details). The flags SEQE, SWE and WPVS are automatically cleared when SMC_WPSR is read.

If one of these flags is set, an interrupt can be triggered if the SMC_SRIER.SRIE bit is ‘1’.

20.18. Scrambling/Unscrambling Function

The external data bus can be scrambled to make more difficult the recovery of intellectual property data located in off-chip memories by means of data analysis at the package pin level of either the microcontroller or the memory device.

The scrambling and unscrambling are performed on-the-fly without additional wait states.

The scrambling/unscrambling function can be enabled or disabled by configuring the CSxSE bits in the SMC Off-Chip Memory Scrambling Register (SMC_OCMS).

When multiple chip selects are handled, the scrambling function per chip select is configurable using the CSxSE bits in the SMC_OCMS register.

The scrambling method depends on two user-configurable key registers, SMC_KEY1 and SMC_KEY2 plus a random value depending on device processing characteristics. These key registers cannot be read. They can be written once after a system reset.

The scrambling user key or the seed for key generation must be securely stored in a reliable non-volatile memory in order to recover data from the off-chip memory. Any data scrambled with a given key cannot be recovered if the key is lost.

20.19. Clearing Scrambling Keys on a Tamper Event

On a tamper detection event on WKUP pins, it is possible to perform an immediate clear of the scrambling keys (SMC_KEY1 and SMC_KEY2) if SMC_OCMS.TAMPCLR is set.

© 2026 Microchip Technology Inc. and its subsidiaries

20.20. Register Summary

The SMC is programmed using the registers listed below. For each chip select, a set of four registers is used to program the parameters of the external device connected on it. The number of SMC_SETUP, SMC_PULSE, SMC_CYCLE and SMC_MODE registers depends on the number of chip selects. Sixteen bytes (0x10) are required per chip select.

Note: The user must confirm the SMC configuration by writing any one of the SMC_MODE registers.

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0

20.20.1. SMC Setup Register

Name: SMC_SETUPx
Offset: 0x00 + x*0x04 [x=0..2]
Reset: 0x01010101
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

Note: The number of SMC_SETUP registers depends on the chip select number.

Bit	31	30	29	28	27	26	25	24
			NCS_RD_SETUP[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	0	1

Bit	23	22	21	20	19	18	17	16
			NRD_SETUP[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	0	1

Bit	15	14	13	12	11	10	9	8
			NCS_WR_SETUP[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	0	1

Bit	7	6	5	4	3	2	1	0
			NWE_SETUP[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	0	1

Bits 29:24 – NCS_RD_SETUP[5:0] NCS Setup Length in READ Access
In READ access, the NCS signal setup length is defined as:
NCS setup length = (128 * NCS_RD_SETUP[5] + NCS_RD_SETUP[4:0]) clock cycles

Bits 21:16 – NRD_SETUP[5:0] NRD Setup Length
The NRD signal setup length is defined in clock cycles as:
NRD setup length = (128 * NRD_SETUP[5] + NRD_SETUP[4:0]) clock cycles

Bits 13:8 – NCS_WR_SETUP[5:0] NCS Setup Length in WRITE Access
In WRITE access, the NCS signal setup length is defined as:
NCS setup length = (128 * NCS_WR_SETUP[5] + NCS_WR_SETUP[4:0]) clock cycles

Bits 5:0 – NWE_SETUP[5:0] NWE Setup Length
The NWE signal setup length is defined as:
NWE setup length = (128 * NWE_SETUP[5] + NWE_SETUP[4:0]) clock cycles

© 2026 Microchip Technology Inc. and its subsidiaries

20.20.2. SMC Pulse Register

Name: SMC_PULSEx
Offset: 0x04 + x*0x04 [x=0..2]
Reset: 0x01010101
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

Note: The number of SMC_PULSE registers depends on the chip select number.

Bit	31	30	29	28	27	26	25	24
		NCS_RD_PULSE[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	1

Bit	23	22	21	20	19	18	17	16
		NRD_PULSE[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	1

Bit	15	14	13	12	11	10	9	8
		NCS_WR_PULSE[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	1

Bit	7	6	5	4	3	2	1	0
		NWE_PULSE[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	1

Bits 30:24 – NCS_RD_PULSE[6:0] NCS Pulse Length in READ Access
In standard read access, the NCS signal pulse length is defined as:
NCS pulse length = (256 * NCS_RD_PULSE[6] + NCS_RD_PULSE[5:0]) clock cycles
The NCS pulse length must be at least 1 clock cycle.
In Page mode read access, the NCS_RD_PULSE parameter defines the duration of the first access to one page.

Bits 22:16 – NRD_PULSE[6:0] NRD Pulse Length
In standard read access, the NRD signal pulse length is defined in clock cycles as:
NRD pulse length = (256 * NRD_PULSE[6] + NRD_PULSE[5:0]) clock cycles
The NRD pulse length must be at least 1 clock cycle.
In Page mode read access, the NRD_PULSE parameter defines the duration of the subsequent accesses in the page.

Bits 14:8 – NCS_WR_PULSE[6:0] NCS Pulse Length in WRITE Access
In write access, the NCS signal pulse length is defined as:
NCS pulse length = (256 * NCS_WR_PULSE[6] + NCS_WR_PULSE[5:0]) clock cycles
The NCS pulse length must be at least 1 clock cycle.

Bits 6:0 – NWE_PULSE[6:0] NWE Pulse Length
The NWE signal pulse length is defined as:
NWE pulse length = (256 * NWE_PULSE[6] + NWE_PULSE[5:0]) clock cycles
The NWE pulse length must be at least 1 clock cycle.

© 2026 Microchip Technology Inc. and its subsidiaries

20.20.3. SMC Cycle Register

Name: SMC_CYCLEx
Offset: 0x08 + x*0x04 [x=0..2]
Reset: 0x00030003
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

Note: The number of SMC_CYCLE registers depends on the chip select number.

Bit	31	30	29	28	27	26	25	24
								NRD_CYCLE[8]
Access								R/W
Reset								0

Bit	23	22	21	20	19	18	17	16
	NRD_CYCLE[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	1	1

Bit	15	14	13	12	11	10	9	8
								NWE_CYCLE[8]
Access								R/W
Reset								0

Bit	7	6	5	4	3	2	1	0
	NWE_CYCLE[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	1	1

Bits 24:16 – NRD_CYCLE[8:0] Total Read Cycle Length
The total read cycle length is the total duration in clock cycles of the read cycle. It is equal to the sum of the setup, pulse and hold steps of the NRD and NCS signals. It is defined as:
Read cycle length = (NRD_CYCLE[8:7] * 256 + NRD_CYCLE[6:0]) clock cycles

Bits 8:0 – NWE_CYCLE[8:0] Total Write Cycle Length
The total write cycle length is the total duration in clock cycles of the write cycle. It is equal to the sum of the setup, pulse and hold steps of the NWE and NCS signals. It is defined as:
Write cycle length = (NWE_CYCLE[8:7] * 256 + NWE_CYCLE[6:0]) clock cycles

© 2026 Microchip Technology Inc. and its subsidiaries

20.20.4. SMC Mode Register

Name: SMC_MODEx
Offset: 0x0C + x*0x04 [x=0..2]
Reset: 0x10001000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

The user must confirm the SMC configuration by writing any one of the SMC_MODE registers.

Note: The number of SMC_MODE registers depends on the chip select number.

Bit	31	30	29	28	27	26	25	24
			PS[1:0]					PMEN
Access			R/W	R/W				R/W
Reset			0	1				0

Bit	23	22	21	20	19	18	17	16
				TDF_MODE	TDF_CYCLES[3:0]			
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
			DBW[1:0]					BAT
Access			R/W	R/W				R/W
Reset			0	1				0

Bit	7	6	5	4	3	2	1	0
			EXNW_MODE[1:0]				WRITE_MODE	READ_MODE
Access			R/W	R/W			R/W	R/W
Reset			0	0			0	0

Bits 29:28 – PS[1:0] Page Size
If Page mode is enabled, this field indicates the size of the page in bytes.

Value	Name	Description
0	BYTE_4	4-byte page
1	BYTE_8	8-byte page
2	BYTE_16	16-byte page
3	BYTE_32	32-byte page

Bit 24 – PMEN Page Mode Enabled

Value	Description
1	Asynchronous burst read in Page mode is applied on the corresponding chip select.
0	Standard read is applied.

Bit 20 – TDF_MODE TDF Optimization

Value	Description
1	TDF optimization enabled—The number of TDF Wait states is optimized using the setup period of the next read/write access.
0	TDF optimization disabled—The number of TDF Wait states is inserted before the next access begins.

© 2026 Microchip Technology Inc. and its subsidiaries

Bits 19:16 – TDF_CYCLES[3:0] Data Float Time

This field shows the integer number of clock cycles required by the external device to release the data after the rising edge of the read controlling signal. The SMC always provides one full cycle of bus turnaround after the TDF_CYCLES period. The external bus cannot be used by another chip select during TDF_CYCLES + 1 cycles. From 0 up to 15 TDF_CYCLES can be set.

Bits 13:12 – DBW[1:0] Data Bus Width

Value	Name	Description
0	BIT_8	8-bit bus
1	BIT_16	16-bit bus
2	—	Reserved
3	—	Reserved

Bit 8 – BAT Byte Access Type

This field is used only if DBW defines a 16-bit data bus.

Value	Name	Description
0	BYTE_SELECT	Byte select access type: • Write operation is controlled using NCS, NWE, NBS0, NBS1 • Read operation is controlled using NCS, NRD, NBS0, NBS1
1	BYTE_WRITE	Byte write access type: • Write operation is controlled using NCS, NWR0, NWR1 • Read operation is controlled using NCS and NRD

Bits 5:4 – EXNW_MODE[1:0] NWAIT Mode

The NWAIT signal is used to extend the current read or write signal. It is only taken into account during the pulse phase of the read and write controlling signal. When the use of NWAIT is enabled, at least one cycle hold duration must be programmed for the read and write controlling signal.

Value	Name	Description
0	DISABLED	Disabled Mode—The NWAIT input signal is ignored on the corresponding Chip Select.
1	—	Reserved
2	FROZEN	Frozen Mode—If asserted, the NWAIT signal freezes the current read or write cycle. After deassertion, the read/write cycle is resumed from the point where it was stopped.
3	READY	Ready Mode—The NWAIT signal indicates the availability of the external device at the end of the pulse of the controlling read or write signal, to complete the access. If high, the access normally completes. If low, the access is extended until NWAIT returns high.

Bit 1 – WRITE_MODE Selection of the Control Signal for Write Operation

Value	Name	Description
0	NCS_CTRL	Write operation controlled by NCS signal—If TDF optimization is enabled (TDF_MODE = 1), TDF Wait states will be inserted after the setup of NCS.
1	NWE_CTRL	Write operation controlled by NWE signal—If TDF optimization is enabled (TDF_MODE = 1), TDF Wait states will be inserted after the setup of NWE.

Bit 0 – READ_MODE Selection of the Control Signal for Read Operation

Value	Name	Description
0	NCS_CTRL	Read operation controlled by NCS signal • If TDF cycles are programmed, the external bus is marked busy after the rising edge of NCS. • If TDF optimization is enabled (TDF_MODE = 1), TDF Wait states are inserted after the setup of NCS.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
1	NRD_CTRL	Read operation controlled by NRD signal • If TDF cycles are programmed, the external bus is marked busy after the rising edge of NRD. • If TDF optimization is enabled (TDF_MODE = 1), TDF Wait states are inserted after the setup of NRD.

20.20.5. SMC Off-Chip Memory Scrambling Register

Name: SMC_OCMS
Offset: 0x80
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
						CS2SE	CS1SE	CS0SE
Access						R/W	R/W	R/W
Reset						0	0	0

Bit	7	6	5	4	3	2	1	0
				TAMPCLR				SMSE
Access				R/W				R/W
Reset				0				0

Bits 8, 9, 10 – CSxSE Chip Select (x = 0 to 2) Scrambling Enable

Value	Description
0	Disables scrambling for CSx.
1	Enables scrambling for CSx.

Bit 4 – TAMPCLR Tamper Clear Enable

Value	Description
0	A tamper detection event has no effect on SMC scrambling keys.
1	A tamper detection event immediately clears SMC scrambling keys.

Bit 0 – SMSE Static Memory Controller Scrambling Enable

Value	Description
0	Disables scrambling for SMC access.
1	Enables scrambling for SMC access.

© 2026 Microchip Technology Inc. and its subsidiaries

20.20.6. SMC Off-Chip Memory Scrambling Key1 Register

Name: SMC_KEY1
Offset: 0x84
Reset: 0x00000000
Property: Write-only

This register is a 'Write-once' register: the first write access after a system reset prevents any further modification of the register value.

This register is erased if a tamper is detected on fast wake-up pins and bit SMC_OCMS.TAMPCLR = 1.

Bit	31	30	29	28	27	26	25	24

20.20.7. SMC Off-Chip Memory Scrambling Key2 Register

Name: SMC_KEY2
Offset: 0x88
Reset: 0x00000000
Property: Write-only

This register is a 'Write-once' register: the first write access after a system reset prevents any further modification of the register value.

This register is erased if a tamper is detected on fast wake-up pins and bit SMC_OCMS.TAMPCLR = 1.

Bit	31	30	29	28	27	26	25	24

					SWE	SEQE		WPVS
Access					R	R		R
Reset					0	0		0

Bits 25:24 – SWETYP[1:0] Software Error Type (Cleared on read)

Value	Name	Description
0	READ_WO	A write-only register has been read.
1	WRITE_WO	A write access has been performed on a read-only register.
2	UNDEF_RW	Access to an undefined address.

Bits 23:8 – WPVSRC[15:0] Write Protection Violation Source
When WPVS = 1, WPVSRC indicates the register address offset at which a write access has been attempted.

Bit 3 – SWE Software Control Error (Cleared on read)

Value	Description
0	No software error has occurred since the last read of SMC_WPSR.
1	A software error has occurred since the last read of SMC_WPSR. The field SWETYP details the type of software error; the associated incorrect software access is reported in the field WPVSRC (if WPVS=0).

Bit 2 – SEQE Internal Sequencer Error (Cleared on read)

Value	Description
0	No internal sequencer error has occurred since the last read of SMC_WPSR.
1	An internal sequencer error has occurred since the last read of SMC_WPSR. This flag can only be set under abnormal operating conditions.

Bit 0 – WPVS Write Protection Violation Status

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	No write protection violation has occurred since the last read of the SMC_WPSR.
1	A write protection violation occurred since the last read of the SMC_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSRC.

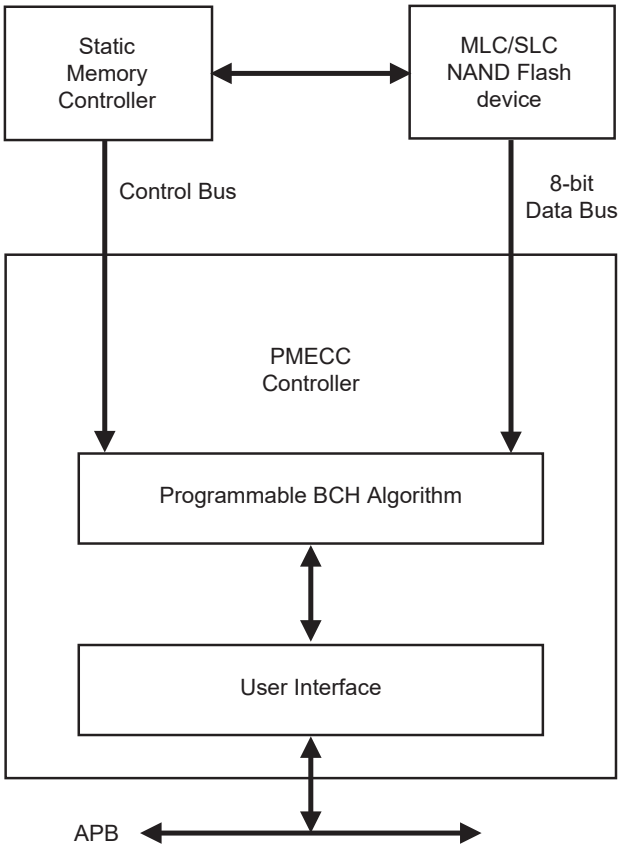
21. Programmable Multibit Error Correction Code Controller (PMECC)

21.1. Description

The Programmable Multibit Error Correction Code Controller (PMECC) is a programmable binary BCH (Bose, Chaudhuri and Hocquenghem) encoder/decoder. This controller can be used to generate redundancy information for both Single-Level Cell (SLC) and Multi-level Cell (MLC) NAND Flash devices. It supports redundancy for correction of 2, 4, 8, 12 or 24 bits of error per sector of data.



21.2. Embedded Characteristics

- 8-bit NAND Flash Data Bus Support
- Multibit Error Correcting Code
- Algorithm Based on Binary Shortened Bose, Chaudhuri and Hocquenghem (BCH) Codes
- Programmable Error Correcting Capability: 2, 4, 8, 12 and 24 Bits of Error per Sector
- Programmable Sector Size: 512 Bytes or 1024 Bytes
- Programmable Number of Sectors per Page: 1, 2, 4 or 8 Sectors of Data per Page
- Programmable Spare Area Size
- Supports Spare Area ECC Protection
- Supports 8 Kbytes Page Size Using 1024 Bytes per Sector and 4 Kbytes Page Size Using 512 Bytes per Sector
- Configurable through APB Interface
- Interrupt-Driven Multibit Error Detection

© 2026 Microchip Technology Inc. and its subsidiaries

21.3. Block Diagram

Figure 21.1. PMECC Block Diagram

21.4. Functional Description

The NAND Flash sector size is programmable and can be set to 512 bytes or 1024 bytes. The PMECC module generates redundancy at encoding time, when a NAND write page operation is performed. The redundancy is appended to the page and written in the spare area. This operation is performed by the processor. It moves the content of the PMECCx registers into the NAND Flash memory. The number of registers depends on the selected error correction capability (see Table 21.1). This operation is executed for each sector. At decoding time, the PMECC module generates the remainder of the received codeword by minimal polynomials. When all polynomial remainders for a given sector are set to zero, no error occurred. When the polynomial remainders are other than zero, the codeword is corrupted and further processing is required.

The PMECC generates an interrupt indicating that an error occurred. The processor must read the Interrupt Status register (PMECC_ISR). This register indicates which sector is corrupted.

To find the error location within a sector, the processor must execute the following decoding steps:

1. Syndrome computation
2. Find the error locator polynomials
3. Find the roots of the error locator polynomial

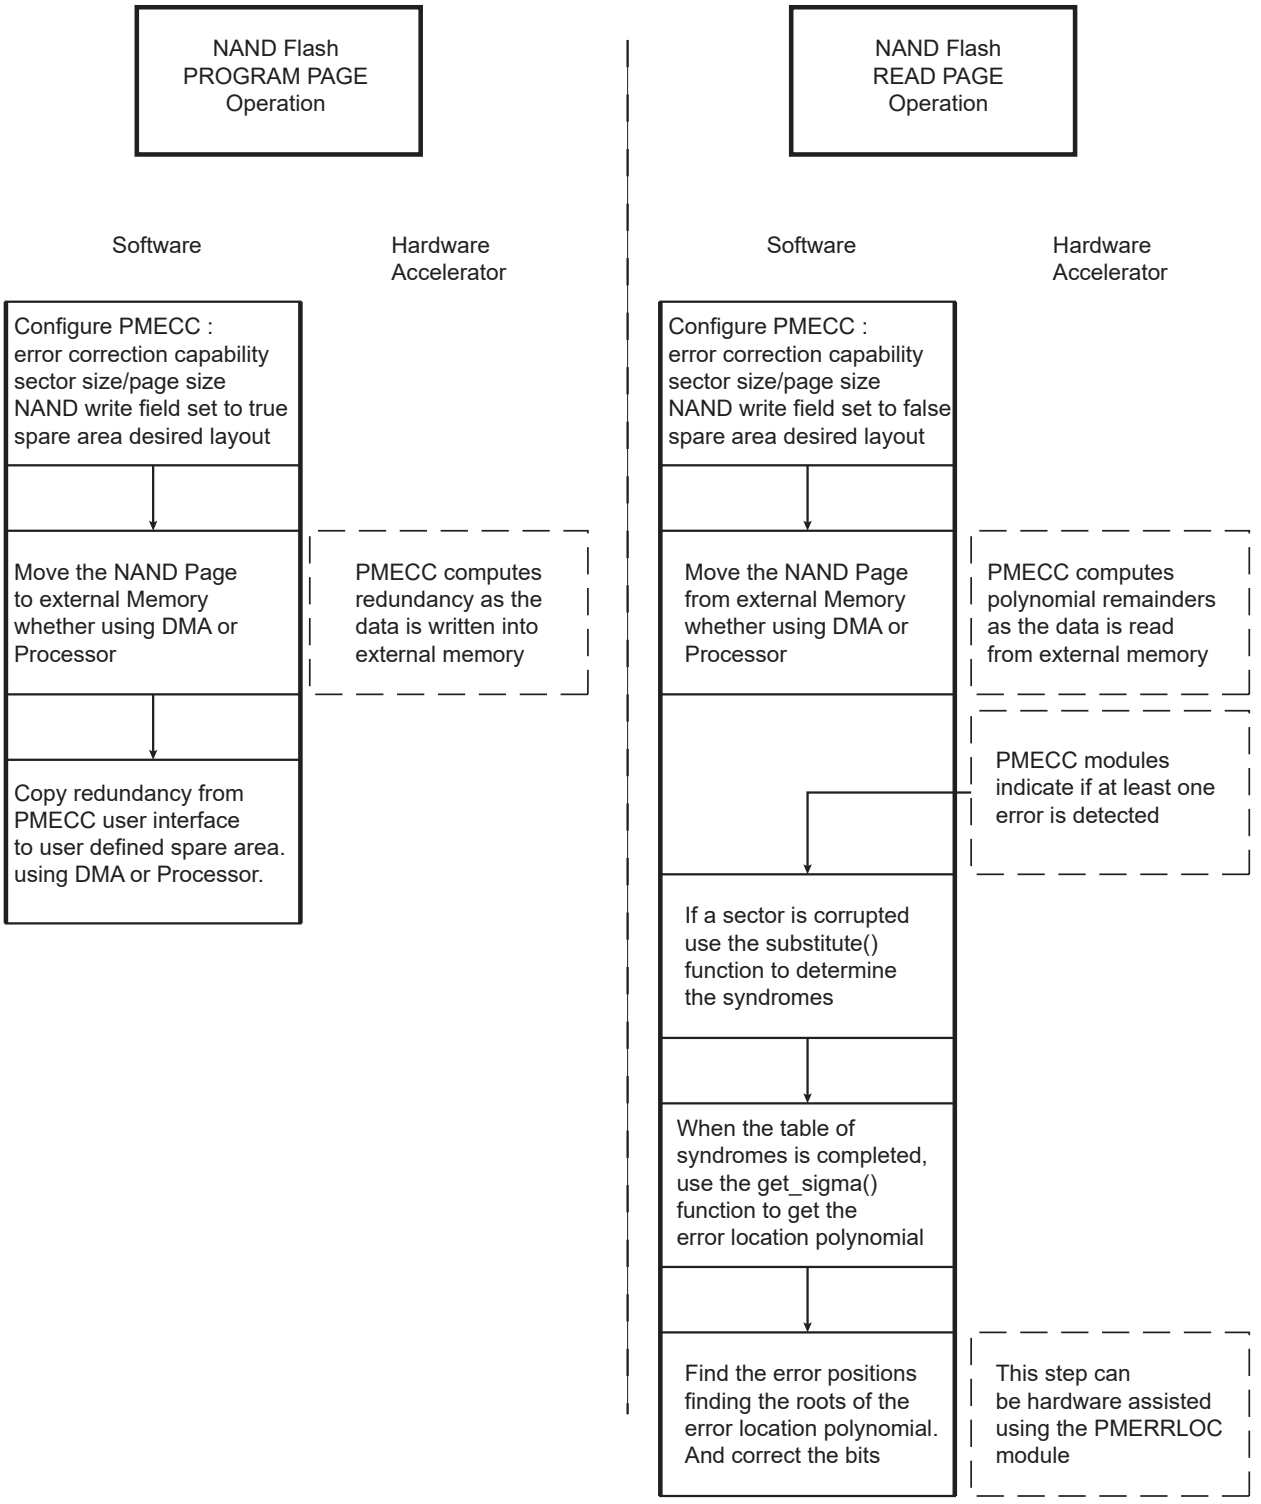
All decoding steps involve finite field computation, for which a library of finite field arithmetic must be available to perform addition, multiplication and inversion. The finite field arithmetic operations can be performed through the use of a memory mapped lookup table, or direct software implementation. The software implementation presented is based on lookup tables. Two tables named gf_log and gf_antilog are used. If alpha is the primitive element of the field, then a power of

© 2026 Microchip Technology Inc. and its subsidiaries

alpha is in the field. Assume beta = alpha ^ index, then beta belongs to the field, and gf_log(beta) = gf_log(alpha ^ index) = index. The gf_antilog tables provide exponent inverse of the element, if beta = alpha ^ index, then gf_antilog(index) = beta.

The first step consists of the syndrome computation. The PMECC computes the remainders and software must substitute the power of the primitive element.

The procedure implementation is described in Remainder Substitution Procedure.



The second step is the most software intensive. It is the Berlekamp's iterative algorithm for finding the error-location polynomial.

The procedure implementation is described in Find the Error Location Polynomial Sigma(x).

The last step is finding the root of the error location polynomial. This step can be very software intensive, as there is no straightforward method of finding the roots, except by evaluating each element of the field in the error location polynomial. However, a hardware accelerator can be used to find the roots of the polynomial. The Programmable Multibit Error Correction Code Location (PMERRLOC) module provides this type of hardware acceleration.

21.4.1. MLC/SLC Write Page Operation using PMECC

When an MLC write page operation is performed, the PMECC controller is configured with the NANDWR bit in the Configuration register (PMECC_CFG) set to one. When the NAND spare area contains file system information and redundancy (PMECCx), the spare area is error protected,

© 2026 Microchip Technology Inc. and its subsidiaries

then PMECC_CFG.SPAREEN is set to '1'. When the NAND spare area contains only redundancy information, SPAREEN is set to '0'.

When the write page operation is terminated, the user writes the redundancy in the NAND spare area. This operation can be done with DMA assistance.

Table 21.1. Relevant Redundancy Registers

BCH_ERR Field	Sector Size Set to 512 Bytes	Sector Size Set to 1024 Bytes
0	PMECC_ECC0	PMECC_ECC0
1	PMECC_ECC0, PMECC_ECC1	PMECC_ECC0, PMECC_ECC1
2	PMECC_ECC0, PMECC_ECC1, PMECC_ECC2, PMECC_ECC3	PMECC_ECC0, PMECC_ECC1, PMECC_ECC2, PMECC_ECC3
3	PMECC_ECC0, PMECC_ECC1, PMECC_ECC2, PMECC_ECC3, PMECC_ECC4, PMECC_ECC5, PMECC_ECC6	PMECC_ECC0, PMECC_ECC1, PMECC_ECC2, PMECC_ECC3, PMECC_ECC4, PMECC_ECC5, PMECC_ECC6
4	PMECC_ECC0, PMECC_ECC1, PMECC_ECC2, PMECC_ECC3, PMECC_ECC4, PMECC_ECC5, PMECC_ECC6, PMECC_ECC7, PMECC_ECC8, PMECC_ECC9	PMECC_ECC0, PMECC_ECC1, PMECC_ECC2, PMECC_ECC3, PMECC_ECC4, PMECC_ECC5, PMECC_ECC6, PMECC_ECC7, PMECC_ECC8, PMECC_ECC9, PMECC_ECC10

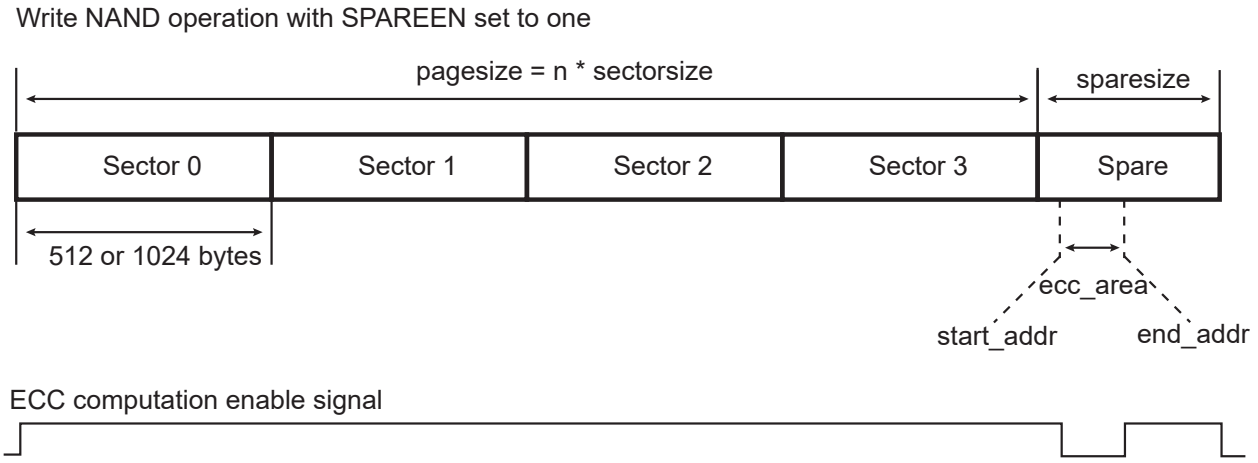

Table 21.2. Number of Relevant ECC Bytes per Sector, Copied from LSbyte to MSbyte

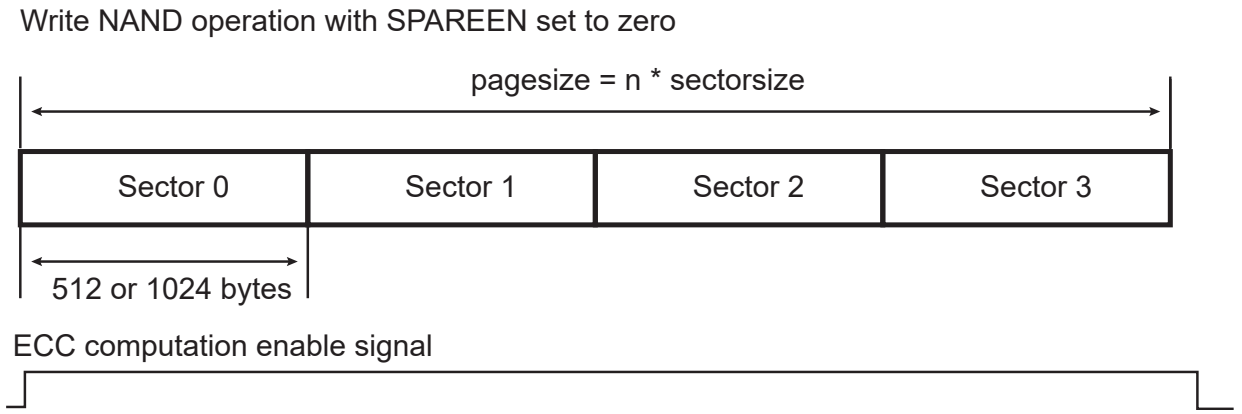
BCH_ERR Field	Sector Size Set to 512 Bytes	Sector Size Set to 1024 Bytes
0	4 bytes	4 bytes
1	7 bytes	7 bytes
2	13 bytes	14 bytes
3	20 bytes	21 bytes
4	39 bytes	42 bytes

21.4.1.1. SLC/MLC Write Operation with Spare Enable Bit Set

When PMECC_CFG.SPAREEN is set to '1', the spare area of the page is encoded with the stream of data of the last sector of the page. This mode is entered by writing one in the DATA bit in the Control register (PMECC_CTRL). When the encoding process is over, the redundancy is written to the spare area in user mode, PMECC_CTRL.USER must be set to '1'.

Figure 21.3. NAND Write Operation with Spare Encoding



21.4.1.2. MLC/SLC Write Operation with Spare Area Disabled

When PMECC_CFG.SPAREEN is set to '0', the spare area is not encoded with the stream of data. This mode is entered by writing '1'to PMECC_CTRL.DATA.

Figure 21.4. NAND Write Operation

21.4.2. MLC/SLC Read Page Operation using PMECC

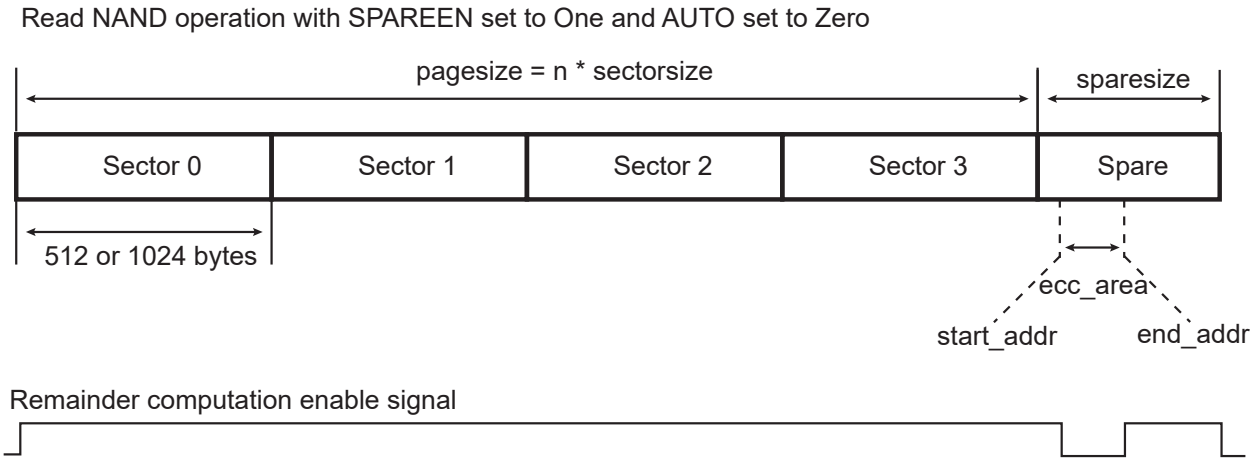

Table 21.3. Relevant Remainders Registers

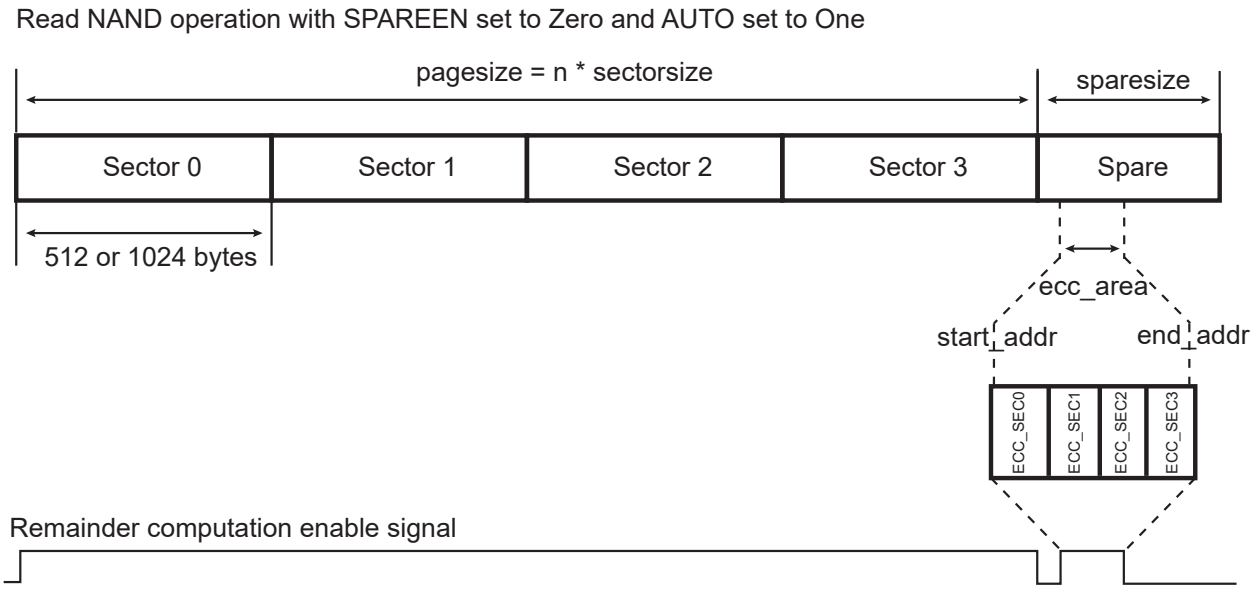
BCH_ERR Field	Sector Size Set to 512 Bytes	Sector Size Set to 1024 Bytes
0	PMECC_REM0	PMECC_REM0
1	PMECC_REM0, PMECC_REM1	PMECC_REM0, PMECC_REM1
2	PMECC_REM0, PMECC_REM1, PMECC_REM2, PMECC_REM3,	PMECC_REM0, PMECC_REM1, PMECC_REM2, PMECC_REM3
3	PMECC_REM0, PMECC_REM1, PMECC_REM2, PMECC_REM3, PMECC_REM4, PMECC_REM5, PMECC_REM6, PMECC_REM7	PMECC_REM0, PMECC_REM1, PMECC_REM2, PMECC_REM3, PMECC_REM4, PMECC_REM5, PMECC_REM6, PMECC_REM7
4	PMECC_REM0, PMECC_REM1, PMECC_REM2, PMECC_REM3, PMECC_REM4, PMECC_REM5, PMECC_REM6, PMECC_REM7, PMECC_REM8, PMECC_REM9, PMECC_REM10, PMECC_REM11	PMECC_REM0, PMECC_REM1, PMECC_REM2, PMECC_REM3, PMECC_REM4, PMECC_REM5, PMECC_REM6, PMECC_REM7, PMECC_REM8, PMECC_REM9, PMECC_REM10, PMECC_REM11

21.4.2.1. MLC/SLC Read Operation with Spare Decoding

When the spare area is protected, the spare area contains valid data. As the redundancy may be included in the middle of the information stream, the user programs the start address and the end address of the ECC area. The controller will automatically skip the ECC area. This mode is entered by writing a '1' to PMECC_CTRL.DATA. When the page has been fully retrieved from NAND, the ECC area is read using the user mode by writing a '1' to PMECC_CTRL.USER.

Figure 21.5. Read Operation with Spare Decoding

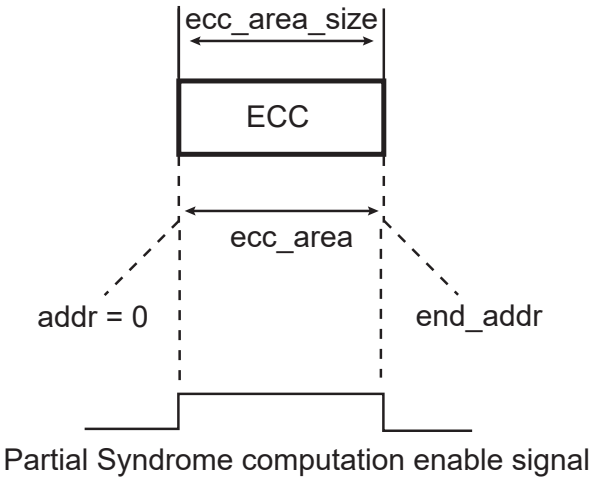


© 2026 Microchip Technology Inc. and its subsidiaries

21.4.2.2. MLC/SLC Read Operation

If the spare area is not protected with the error correcting code, the redundancy area is retrieved directly. This mode is entered by writing a '1' to PMECC_CTRL.DATA. When PMECC_CFG.AUTO is set to '1', the ECC is retrieved automatically, otherwise the ECC must be read using user mode.

Figure 21.6. Read Operation



21.4.2.3. MLC/SLC User Read ECC Area

This mode allows a manual retrieve of the ECC.

This mode is entered by writing a '1' to PMECC_CTRL.USER.

Figure 21.7. User Read Mode

21.5. Software Implementation

21.5.1. Remainder Substitution Procedure

The substitute function evaluates the polynomial remainder, with different values of the field primitive elements. The finite field arithmetic addition operation is performed with the Exclusive or. The finite field arithmetic multiplication operation is performed through the gf_log, gf_antilog lookup tables.

© 2026 Microchip Technology Inc. and its subsidiaries

The REM2NP1 and REMN2NP3 fields of the PMECC Remainder x registers (PMECC_REMx) contain only odd remainders. Each bit indicates whether the coefficient of the polynomial remainder is set to zero or not.

NB_ERROR_MAX defines the maximum value of the error correcting capability.

NB_ERROR defines the error correcting capability selected at encoding/decoding time.

NB_FIELD_ELEMENTS defines the number of elements in the field.

si[] is a table that holds the current syndrome value, an element of that table belongs to the field. This is also a shared variable for the next step of the decoding operation.

oo[] is a table that contains the degree of the remainders.

```
int substitute()
    {
    int i;
    int j;
    for (i = 1; i < 2 * NB_ERROR_MAX;
        i++)
    {
     si[i] = 0;
    }
    for (i = 1; i < 2*NB_ERROR;
        i++)
    {
     for (j = 0; j < oo[i];
      j++)
     {
      if (REM2NPX[i][j])
      {
       si[i] = gf_antilog[(i *
        j)%NB_FIELD_ELEMENTS] ^ si[i];
      }
     }
    }
    return 0;
    }
```

21.5.2. Find the Error Location Polynomial Sigma(x)

The sample code below provides a Berlekamp iterative procedure used to find the value of the error location polynomial.

The input of the procedure is the si[] table defined in the remainder substitution procedure.

The output of the procedure is the error location polynomial named smu (sigma mu). The polynomial coefficients belong to the field. The smu[NB_ERROR+1][] is a table that contains all these coefficients.

NB_ERROR_MAX defines the maximum value of the error correcting capability.

NB_ERROR defines the error correcting capability selected at encoding/decoding time.

NB_FIELD_ELEMENTS defines the number of elements in the field.

```
int get_sigma()
    {
    int i;
    int j;
    int k;
    /* mu           */
    int
      mu[NB_ERROR_MAX+2];
    /* sigma ro    */
    int
      sro[2*NB_ERROR_MAX+1];
    /* discrepancy */
    int
      dmu[NB_ERROR_MAX+2];
    /* delta order   */
    int
```

}
}
return 0;
}
```

21.5.3. Find the Error Position

The output of the get_sigma() procedure is a polynomial stored in the smu[NB_ERROR+1][] table. The error position is the roots of that polynomial. The degree of this polynomial is very important information, as it provides the number of errors. The PMERRLOC module provides a hardware accelerator for this step.

21.6.1. PMECC Configuration Register

Name: PMECC_CFG
Offset: 0x000
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
				AUTO				SPAREEN
Access				R/W				R/W
Reset				0				0

Bit	15	14	13	12	11	10	9	8
				NANDWR			PAGESIZE[1:0]	
Access				R/W			R/W	R/W
Reset				0			0	0

Bit	7	6	5	4	3	2	1	0
				SECTORSZ		BCH_ERR[2:0]		
Access				R/W		R/W	R/W	R/W
Reset				0		0	0	0

Bit 20 – AUTO Automatic Mode Enable
This bit is only relevant in NAND Read Mode, when spare enable is activated.

Value	Description
0	Indicates that the spare area is not protected. In that case the ECC computation takes into account the ECC area located in the spare area (within the start address and the end address).
1	Indicates that the spare is error protected. In this case, the ECC computation takes into account the whole spare area minus the ECC area in the ECC computation operation.

Bit 16 – SPAREEN Spare Enable

- For NAND write access:
  — 0: The spare area is skipped
  — 1: The spare area is protected with the last sector of data.
- For NAND read access:
  — 0: The spare area is skipped.
  — 1: The spare area contains protected data or only redundancy information.

Bit 12 – NANDWR NAND Write Access

Value	Description
0	NAND read access
1	NAND write access

Bits 9:8 – PAGESIZE[1:0] Number of Sectors in the Page

Value	Name	Description
0	PAGESIZE_1SEC	1 sector for main area (512 or 1024 bytes)

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
1	PAGESIZE_2SEC	2 sectors for main area (1024 or 2048 bytes)
2	PAGESIZE_4SEC	4 sectors for main area (2048 or 4096 bytes)
3	PAGESIZE_8SEC	8 errors for main area (4096 or 8192 bytes)

Bit 4 – SECTORSZ Sector Size

Value	Description
0	The ECC computation is based on a sector of 512 bytes.
1	The ECC computation is based on a sector of 1024 bytes.

Bits 2:0 – BCH_ERR[2:0] Error Correct Capability

Value	Name	Description
0	BCH_ERR2	2 errors
1	BCH_ERR4	4 errors
2	BCH_ERR8	8 errors
3	BCH_ERR12	12 errors
4	BCH_ERR24	24 errors

Bit	15	14	13	12	11	10	9	8
								STARTADDR[8]
Access								R/W
Reset								0

Bit	7	6	5	4	3	2	1	0
	STARTADDR[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 8:0 – STARTADDR[8:0] ECC Area Start Address (byte oriented address)
This field indicates the first byte address of the ECC area. Location 0 matches the first byte of the spare area.

© 2026 Microchip Technology Inc. and its subsidiaries

21.6.4. PMECC End Address Register

Name: PMECC_EADDR
Offset: 0x00C
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 8:0 – ENDADDR[8:0] ECC Area End Address (byte oriented address)
This field indicates the last byte address of the ECC area.

© 2026 Microchip Technology Inc. and its subsidiaries

21.6.5. PMECC Control Register

Name: PMECC_CTRL
Offset: 0x014
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			DISABLE	ENABLE		USER	DATA	RST
Access			W	W		W	W	W
Reset			–	–		–	–	–

Bit 5 – DISABLE PMECC Module Disable
The PMECC module must always be configured after being deactivated.

Bit 4 – ENABLE PMECC Module Enable
The PMECC module must always be configured before being activated.

Bit 2 – USER Start a User Mode Phase

Bit 1 – DATA Start a Data Phase

Bit 0 – RST Reset the PMECC Module
When set to one, this bit resets the PMECC Controller; configuration registers remain unaffected.

© 2026 Microchip Technology Inc. and its subsidiaries

21.6.6. PMECC Status Register

Name: PMECC_SR
Offset: 0x018
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
				ENABLE				BUSY
Access				R				R
Reset				0				0

Bit 4 – ENABLE PMECC Module Status

Value	Description
0	The PMECC module is disabled and can be configured.
1	The PMECC module is enabled and the configuration registers cannot be written.

Bit 0 – BUSY Kernel of the PMECC is Busy

© 2026 Microchip Technology Inc. and its subsidiaries

21.6.7. PMECC Interrupt Enable Register

Name: PMECC_IER
Offset: 0x01C
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	ERRIS[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 7:0 – ERRIS[7:0] Error Interrupt Status
When set to one, bit i of the PMECC_ISR indicates that sector i is corrupted.

© 2026 Microchip Technology Inc. and its subsidiaries

21.6.11. PMECC ECC x Register

Name: PMECC_ECCx
Offset: 0x40 + x*0x04 [x=0..10]
Reset: 0xFFFFFFFF
Property: Read-only

Note: The block of registers PMECC_ECCx[x=0..10] is instanced 8 times in the user interface.

Bit	31	30	29	28	27	26	25	24
	ECC[31:24]							
Access	R	R	R	R	R	R	R	R
Reset	1	1	1	1	1	1	1	1

Bit	23	22	21	20	19	18	17	16
	ECC[23:16]							
Access	R	R	R	R	R	R	R	R
Reset	1	1	1	1	1	1	1	1

Bit	15	14	13	12	11	10	9	8
	ECC[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	1	1	1	1	1	1	1	1

Bit	7	6	5	4	3	2	1	0
	ECC[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	1	1	1	1	1	1	1	1

Bits 31:0 – ECC[31:0] BCH Redundancy
This register contains the remainder of the division of the codeword by the generator polynomial.

© 2026 Microchip Technology Inc. and its subsidiaries

21.6.12. PMECC Remainder x Register

Name: PMECC_REMx
Offset: 0x0240 + x*0x04 [x=0..11]
Reset: 0x00000000
Property: Read-only

Note: The block of registers PMECC_REMx[x=0..11] is instanced 8 times in the user interface.

Bit	31	30	29	28	27	26	25	24
			REM2NP3[13:8]					
Access			R	R	R	R	R	R
Reset			0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	REM2NP3[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
			REM2NP1[13:8]					
Access			R	R	R	R	R	R
Reset			0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	REM2NP1[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 29:16 – REM2NP3[13:0] BCH Remainder 2 * N + 3
When sector size is set to 512 bytes, bit REM2NP3[29] is not used and read as zero.
If bit i of the REM2NP3 field is set to one then the coefficient of the X ^ i is set to one, otherwise the coefficient is zero.

Bits 13:0 – REM2NP1[13:0] BCH Remainder 2 * N + 1
When sector size is set to 512 bytes, bit REM2NP1[13] is not used and read as zero.
If bit i of the REM2NP1 field is set to one then the coefficient of the X ^ i is set to one, otherwise the coefficient is zero.

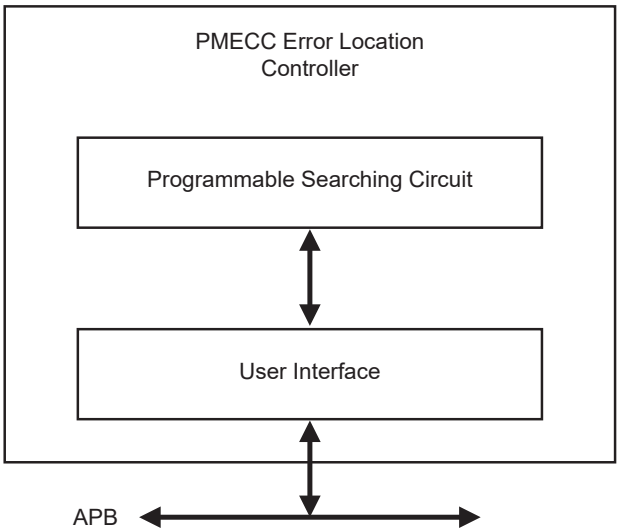
22. Programmable Multibit ECC Error Location Controller (PMERRLOC)

22.1. Description



The PMECC Error Location Controller provides hardware acceleration for determining roots of polynomials over two finite fields: GF(2^13) and GF(2^14). It integrates 24 fully programmable coefficients. These coefficients belong to GF(2^13) or GF(2^14). The coefficient programmed in the PMERRLOC_SIGMAx register is the coefficient of degree x in the polynomial.

22.2. Embedded Characteristics

- Provides Hardware Acceleration to Determine Roots of Polynomials Defined over a Finite Field
- Programmable Finite Field GF(2^13) or GF(2^14)
- Finds Roots of Error Locator Polynomial
- Programmable Number of Roots

22.3. Block Diagram

Figure 22.1. Block Diagram

22.4. Functional Description

The PMERRLOC search operation is started as soon as a write access is detected in the PMERRLOC_ELEN register and can be disabled by writing to the PMERRLOC_ELDIS register. PMERRLOC_ELEN.ENINIT shall be initialized with the number of Galois field elements to test. The set of the roots can be limited to a valid range.

Table 22.1. ENINIT Field Value for a Sector Size of 512 Bytes

Error Correcting Capability	ENINIT Value
2	4122
4	4148
8	4200
12	4252
24	4408

© 2026 Microchip Technology Inc. and its subsidiaries

Table 22.2. ENINIT Field Value for a Sector Size of 1024 Bytes

Error Correcting Capability	ENINIT Value
2	8220
4	8248
8	8304
12	8360
24	8528

When the PMERRLOC is searching for roots, PMERRLOC_ELSR.BUSY remains asserted. An interrupt is asserted at the end of the computation, and PMERRLOC_ELISR.DONE is set. PMERRLOC_ELISR.ERR_CNT indicates the number of errors. The error position can be read in the PMERRLOC_ELx registers.

23. DDR-SDRAM Controller (MPDDRC)

23.1. Description

DDR-SDRAM Controller (MPDDRC) maximizes memory bandwidth and minimizes transaction latency due to the DDR-SDRAM protocol.

The MPDDRC extends the memory capabilities of a chip by providing the interface to the external 16-bit DDR-SDRAM device. The page size supports ranges from 2048 to 16384 rows and from 512 to 4096 columns. It supports word (32-bit), half-word (16-bit), and byte (8-bit) accesses.

The MPDDRC supports a read or write burst length of eight locations. This enables the command and address bus to anticipate the next command, thus reducing latency imposed by the DDR-SDRAM protocol and improving the DDR-SDRAM bandwidth. Moreover, MPDDRC keeps track of the active row in each bank, thus maximizing DDR-SDRAM performance, e.g., the application may be placed in one bank and data in other banks. To optimize performance, avoid accessing different rows in the same bank. The MPDDRC supports a CAS latency of 3, 4, 5 or 6 and optimizes the read access depending on the frequency.

Self-Refresh and Power-Down modes minimize the consumption of the DDR-SDRAM device.

OCD (Off-chip Driver) and ODT (On-die Termination) modes, and Write Leveling, are not supported.

The MPDDRC supports DDR3-SDRAM and DDR3L-SDRAM devices with DLL disabled (DLL Off) and DLL enabled (DLL On).

In DLL Off mode, as per the applicable JEDEC standard, the maximum clock frequency is 125 MHz. However, check with memory suppliers for support for higher speeds. The DLL Off mode sets the CAS Read Latency (CRL) and the CAS Write Latency (CWL) to 6.

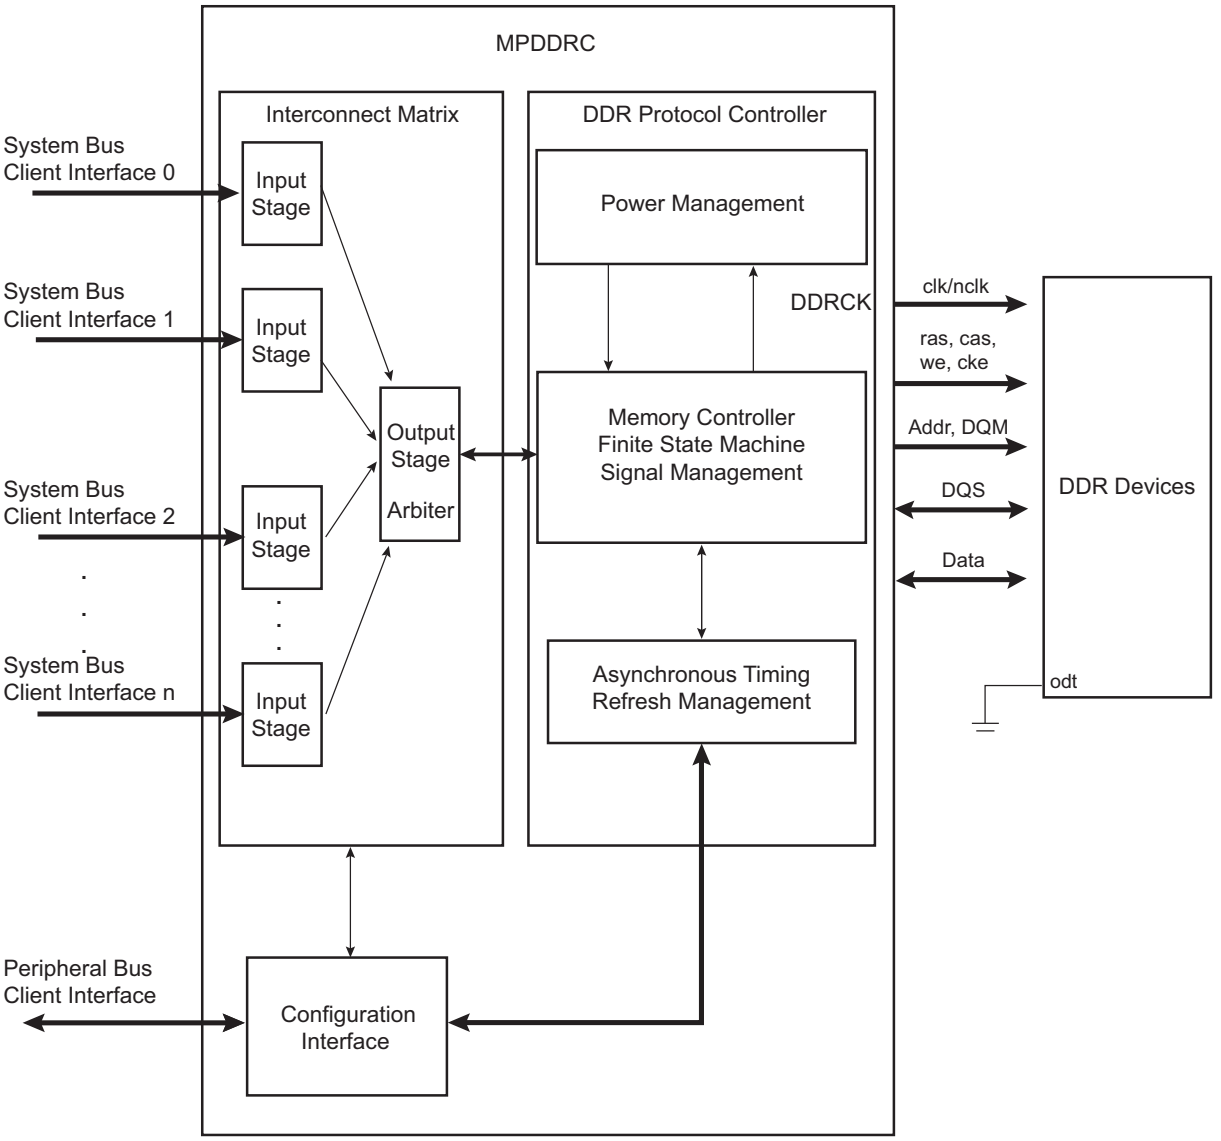
In DLL On mode, as per the applicable JEDEC standard, the minimum clock frequency is 303 MHz. However, check with memory suppliers for support for lower speeds. The DLL On mode sets the CAS Read Latency (CRL) to 6 and the CAS Write Latency (CWL) to 5. DDR3-SDRAM supports high-capacity (1 Gbit and greater) and can reduce power consumption with a 1.5V supply (DDR3-SDRAM) or a 1.35V supply (DDR3L-SDRAM).

23.2. Embedded Characteristics

- Supported Memory Devices:
  - DDR2-SDRAM
  - DDR3-SDRAM (DLL Off/On mode)
  - DDR3L-SDRAM (DLL Off/On mode)
- Arbitration Policies: Round-Robin, On Request, Bandwidth, Quality of Service
- Microchip Technology Non-Blocking Bus Interface Improves Quality of Service
- Multiple Outstanding Bus Transactions Increase Bandwidth (up to 30 %)
- 7 System Bus Interfaces; Management of all Accesses Maximizes Memory Bandwidth and Minimizes Transaction Latency
- Bus Transfer: Word, Half Word, Byte Access
- Supported Configurations:
  - 2K, 4K, 8K, 16K row address memory parts
  - DDR-SDRAM with four or eight internal banks (DDR2-SDRAM/DDR3-SDRAM/DDR3L-SDRAM)
  - DDR-SDRAM with 16-bit data path for system-oriented word access
  - One chip select for SDRAM device (256-Mbyte address space)
- Programming Facilities

© 2026 Microchip Technology Inc. and its subsidiaries

  - Multibank ping-pong access (up to four or eight banks opened at the same time = reduced average latency of transactions)
  - Timing parameters specified by software
  - Automatic refresh operation, refresh rate is programmable
- Energy-Saving Capabilities
  - Self-Refresh, Power-Down and Active Power-Down modes supported
- DDR-SDRAM Power-Up Initialization by Software
- CAS Latency of 3, 4, 5 or 6 Supported
- Reset Function Supported (DDR2-SDRAM)
- Clock Frequency Change in Self-Refresh Mode Supported (/DDR2-SDRAM/DDR3-SDRAM/DDR3L-SDRAM)
- Auto-precharge Command Not Used
- OCD (Off-chip Driver) Mode, ODT (On-die Termination), Write leveling are Not Supported
- Abnormal Software Access and Sequencer Integrity Error Reports
- Dynamic Scrambling with User Key (No Impact on Bandwidth)
- Bus Monitor



23.3. Block Diagram

The MPDDRC is partitioned in two blocks (see figure below):

- An Interconnect Matrix block that manages concurrent accesses on the system bus between 7 system bus hosts and integrates an arbiter
- A DDR Controller that translates system bus requests (read/write) in the DDR-SDRAM protocol

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 23.1. Block Diagram

23.4. Product Dependencies, Initialization Sequence

23.4.1. Interrupt Sources

The MPDDRC interrupt line is connected on one of the internal sources of the interrupt controller. Using the MPDDRC interrupt requires the interrupt controller to be programmed first.

23.4.2. Performance Optimization

To improve Quality of Service and increase the bandwidth, enable the MPDDRC Multiport feature (SFR_CCFG_EBICSA.DDR_MP_EN = 1) and set the type of arbitration to Quality of Service policy (MPDDRC_CONF_ARBITER.ARB = 3).

23.4.3. DDR2-SDRAM Initialization

Set the DDR I/O calibration codes prior to initializing the DDR-SDRAM in SFR_CAL1 register. Write 0x0000_0194 for DDR2-SDRAM.

The initialization sequence is generated by software. The DDR2-SDRAM devices are initialized by the following sequence:

© 2026 Microchip Technology Inc. and its subsidiaries

1. Program the memory device type in the Memory Device register (MPDDRC_MD).
2. Program the shift sampling value in the Read Data Path register (MPDDRC_RD_DATA_PATH).
3. Program MPDDRC_IO_CALIBR.
4. Program features of the DDR2-SDRAM device in the Configuration register (MPDDRC_CR) (number of columns, rows, banks, CAS latency and output driver impedance control) and in the Timing Parameter 0 register/Timing Parameter 1 register (MPDDRC_TPR0/1) (asynchronous timing: TRC, TRAS, etc.).
5. A NOP command is issued to the DDR2-SDRAM. Program the NOP command in the Mode register (MPDDRC_MR). The application must configure the MODE field to 1 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to any DDR2-SDRAM address to acknowledge this command. The clocks which drive the DDR2-SDRAM device are now enabled.
6. A pause of at least 200 µs must be observed before a signal toggle.
7. A NOP command is issued to the DDR2-SDRAM. Program the NOP command in the MPDDRC_MR. The application must configure the MODE field to 1 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to any DDR2-SDRAM address to acknowledge this command. CKE is now driven high.
8. An All Banks Precharge command is issued to the DDR2-SDRAM. Program All Banks Precharge command in the MPDDRC_MR. The application must configure the MODE field to 2 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to any DDR2-SDRAM address to acknowledge this command.
9. An Extended Mode Register Set (EMRS2) cycle is issued to choose between commercial or high temperature operations. The application must configure the MODE field to 5 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to the DDR2-SDRAM to acknowledge this command. The write address must be chosen so that signal BA[1] is set to 1 and signal BA[0] is set to 0. For example: with a 16-bit, 128-Mbit, DDR2-SDRAM (12 rows, 9 columns, 4 banks), the DDR2-SDRAM write access should be done at the address: BASE_ADDRESS_DDR + 0x00800000.
   Note: This address is given as an example only. The real address depends on implementation in the product.
10. An Extended Mode Register Set (EMRS3) cycle is issued to set the Extended Mode register to 0. The application must configure the MODE field to 5 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to the DDR2-SDRAM to acknowledge this command. The write address must be chosen so that signal BA[1] is set to 1 and signal BA[0] is set to 1. For example: with a 16-bit, 128-Mbit, DDR2-SDRAM (12 rows, 9 columns, 4 banks), the DDR2-SDRAM write access should be done at the address: BASE_ADDRESS_DDR + 0x00C00000
11. An Extended Mode Register Set (EMRS1) cycle is issued to enable DLL and to program D.I.C. (Output Driver Impedance Control). The application must configure the MODE field to 5 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to the DDR2-SDRAM to acknowledge this command. The write address must be chosen so that signal BA[1] is set to 0 and signal BA[0] is set to 1. For example: with a 16-bit, 128-Mbit, DDR2-SDRAM (12 rows, 9 columns, 4 banks), the DDR2-SDRAM write access should be done at the address: BASE_ADDRESS_DDR + 0x00400000.
12. An additional 200 cycles of clock are required for locking DLL.
13. Write a ‘1’ to the DLL bit (enable DLL reset) in the Configuration register (MPDDRC_CR).
14. A Mode Register Set (MRS) cycle is issued to reset DLL. The application must configure the MODE field to 3 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to the DDR2-SDRAM to acknowledge this

© 2026 Microchip Technology Inc. and its subsidiaries

command. The write address must be chosen so that signals BA[1:0] are set to 0. For example, the SDRAM write access should be done at the address: BASE_ADDRESS_DDR.

15. An All Banks Precharge command is issued to the DDR2-SDRAM. Program the All Banks Precharge command in the MPDDRC_MR. The application must configure the MODE field to 2 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to any DDR2-SDRAM address to acknowledge this command.
16. Two auto-refresh (CBR) cycles are provided. Program the Auto-refresh command (CBR) in the MPDDRC_MR. The application must configure the MODE field to 4 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to any DDR2-SDRAM location twice to acknowledge these commands. TRFC must be checked between two auto-refreshes (see MPDDRC_TPR1).
17. Write a '0' to the DLL bit (disable DLL reset) in the MPDDRC_CR.
18. A Mode Register Set (MRS) cycle is issued to program parameters of the DDR2-SDRAM device, in particular CAS latency and to disable DLL reset. The application must configure the MODE field to 3 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to the DDR2-SDRAM to acknowledge this command. The write address must be chosen so that signals BA[1:0] are set to 0. For example: with a 16-bit, 128-Mbit, DDR2-SDRAM (12 rows, 9 columns, 4 banks) bank address, the SDRAM write access should be done at the address: BASE_ADDRESS_DDR.
19. Configure the OCD field (default OCD calibration) to 7 in the MPDDRC_CR.
20. An Extended Mode Register Set (EMRS1) cycle is issued to the default OCD value. The application must configure the MODE field to 5 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to the DDR2-SDRAM to acknowledge this command. The write address must be chosen so that signal BA[1] is set to 0 and signal BA[0] is set to 1. For example: with a 16-bit, 128-Mbit, DDR2-SDRAM (12 rows, 9 columns, 4 banks), the DDR2-SDRAM write access should be done at the address: BASE_ADDRESS_DDR + 0x00400000.
21. Configure the OCD field (exit OCD calibration mode) to 0 in the MPDDRC_CR.
22. An Extended Mode Register Set (EMRS1) cycle is issued to enable OCD exit. The application must configure the MODE field to 5 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to the DDR2-SDRAM to acknowledge this command. The write address must be chosen so that signal BA[1] is set to 0 and signal BA[0] is set to 1. For example: with a 16-bit, 128-Mbit, DDR2-SDRAM (12 rows, 9 columns, 4 banks) bank address, the DDR2-SDRAM write access should be done at the address: BASE_ADDRESS_DDR + 0x00400000.
23. A Normal Mode command is provided. Program the Normal mode in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to any DDR2-SDRAM address to acknowledge this command.
24. Write the refresh rate into the COUNT field in the Refresh Timer register (MPDDRC_RTR). To compute the value, see MPDDRC Refresh Timer Register.

After initialization, the DDR2-SDRAM devices are fully functional.

23.4.4. DDR3-SDRAM/DDR3L-SDRAM Initialization

Set the DDR I/O calibration codes prior to initializing the DDR-SDRAM in register SFR_CAL1. Write 0x0000_0126 for DDR3(L)-SDRAM.

The initialization sequence is generated by software. The DDR3-SDRAM devices are initialized by the following sequence:

1. Program the memory device type in the Memory Device register (MPDDRC_MD).

© 2026 Microchip Technology Inc. and its subsidiaries

2. Program the shift sampling value in the Read Data Path register (MPDDRC_RD_DATA_PATH).
3. Program MPDDRC_DDR3_CAL, MPDDRC_DDR3_TIM_CAL, MPDDRC_IO_CALIBR.
4. Set all registers depending on the mode selected (DLL On or DLL Off).
5. Program the features of the DDR3-SDRAM device in the Configuration register (MPDDRC_CR) (number of columns, rows, banks, CAS latency and output driver impedance control, supply value) and in the Timing Parameter 0 register/Timing Parameter 1 register (MPDDRC_TPR0/1) (asynchronous timing - TRC, TRAS, etc.).
6. A NOP command is issued to the DDR3-SDRAM. Program the NOP command in the Mode register (MPDDRC_MR). The application must configure the MODE field to 1 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to any DDR3-SDRAM address to acknowledge this command. The clocks which drive the DDR3-SDRAM device are now enabled.
7. A pause of at least 500 µs must be observed before a signal toggle.
8. A NOP command is issued to the DDR3-SDRAM. Program the NOP command in the MPDDRC_MR. The application must configure the MODE field to 1 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to any DDR3-SDRAM address to acknowledge this command. CKE is now driven high.
9. An Extended Mode Register Set (EMRS2) cycle is issued to choose between commercial or high temperature operations. The application must configure the MODE field to 5 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to the DDR3-SDRAM to acknowledge this command. The write address must be chosen so that signal BA[2] is set to 0, BA[1] is set to 1 and signal BA[0] is set to 0. For example: with a 16-bit, 1-Gbit, DDR3-SDRAM (14 rows, 10 columns, 8 banks), the DDR3-SDRAM write access should be done at the address: BASE_ADDRESS_DDR + 0x040000000; with a 32-bit, 1-Gbit, DDR3-SDRAM (14 rows, 10 columns, 8 banks), the SDRAM write access should be done at the address: BASE_ADDRESS_DDR + 0x08000000.
   Note: This address is given as an example only. The real address depends on the implementation in the product.
10. An Extended Mode Register Set (EMRS3) cycle is issued to set the Extended Mode register to 0. The application must configure the MODE field to 5 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to the DDR3-SDRAM to acknowledge this command. The write address must be chosen so that signal BA[2] is set to 0, BA[1] is set to 1 and signal BA[0] is set to 1. For example: with a 16-bit, 1-Gbit, DDR3-SDRAM (14 rows, 10 columns, 8 banks), the DDR3-SDRAM write access should be done at the address: BASE_ADDRESS_DDR + 0x06000000; with a 32-bit, 1-Gbit, DDR3-SDRAM (14 rows, 10 columns, 8 banks), the SDRAM write access should be done at the address: BASE_ADDRESS_DDR + 0x0C000000.
11. Set MPDDRC_CR.DIS_DLL (Disable DLL) to 1 in DLL Off mode, or to 0 in DLL On mode.
12. An Extended Mode Register Set (EMRS1) cycle is issued to disable and to program ODS (output drive strength). The application must configure the MODE field to 5 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to the DDR3-SDRAM to acknowledge this command. The write address must be chosen so that signal BA[2:1] is set to 0 and signal BA[0] is set to 1. For example: with a 16-bit, 1-Gbit, DDR3-SDRAM (14 rows, 10 columns, 8 banks), the DDR3-SDRAM write access should be done at the address: BASE_ADDRESS_DDR + 0x02000000; with a 32-bit, 1-Gbit, DDR3-SDRAM (14 rows, 10 columns, 8 banks), the SDRAM write access should be done at the address: BASE_ADDRESS_DDR + 0x04000000.
13. Write a ‘1’ to the DLL bit (enable DLL reset) in the Configuration register (MPDDRC_CR).
14. A Mode Register Set (MRS) cycle is issued to reset DLL. The application must configure the MODE field to 3 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler

© 2026 Microchip Technology Inc. and its subsidiaries

instruction just after the read. Perform a write access to the DDR3-SDRAM to acknowledge this command. The write address must be chosen so that signals BA[2:0] are set to 0. For example, the SDRAM write access should be done at the address: BASE_ADDRESS_DDR.

15. A Calibration command (MRS) is issued to calibrate RTT and RON values for the Process Voltage Temperature (PVT). The application must configure the MODE field to 6 in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to the DDR3-SDRAM to acknowledge this command. The write address must be chosen so that signals BA[2:0] are set to 0. For example, the SDRAM write access should be done at the address: BASE_ADDRESS_DDR.
16. A Normal Mode command is provided. Program the Normal mode in the MPDDRC_MR. Read the MPDDRC_MR and add a memory barrier assembler instruction just after the read. Perform a write access to any DDR3-SDRAM address to acknowledge this command.
17. Write the refresh rate into the COUNT field in the Refresh Timer register (MPDDRC_RTR). To compute the value, see MPDDRC Refresh Timer Register.

After initialization, the DDR3-SDRAM devices are fully functional.

23.5. Functional Description

23.5.1. DDR-SDRAM Controller Write Cycle

The MPDDRC provides burst access or single access in Normal mode (MPDDRC_MR.MODE = 0). Whatever the access type, the MPDDRC keeps track of the active row in each bank, thus maximizing performance.

The DDR-SDRAM device is programmed with a burst length (bl) equal to 8. This determines the length of a sequential data input by the write command that is set to 8. The latency from write command to data input depends on the memory type, as shown in the following table.

Table 23.1. CAS Write Latency

Memory Devices	CAS Write Latency (CWL)
DDR2-SDRAM	2/3/4
DDR3-SDRAM (DLL On)	6
DDR3-SDRAM (DLL Off)	5

To initiate a single access, the MPDDRC checks if the page access is already open. If row/bank addresses match with the previous row/bank addresses, the controller generates a write command. If the bank addresses are not identical or if bank addresses are identical but the row addresses are not identical, the controller generates a precharge command, activates the new row and initiates a write command. To comply with DDR-SDRAM timing parameters, additional clock cycles are inserted between precharge/active (t_{RP}) commands and active/write (t_{RCD}) commands. As the burst length is set to 8, in case of single access, it has to stop the burst, otherwise seven invalid values may be written. In case of the DDR-SDRAM device, the Burst Stop command is not supported for the burst write operation. So, in order to interrupt the write operation, the DM (data mask) input signal must be set to 1 to mask invalid data (see the following figures), and DQS must continue to toggle.

To initiate a burst access, the MPDDRC uses the transfer type signal provided by the host requesting the access. If the next access is a sequential write access, writing to the DDR-SDRAM device is carried out. If the next access is a write non-sequential access, then an automatic access break is inserted, the MPDDRC generates a precharge command, activates the new row and initiates a write command. To comply with DDR-SDRAM timing parameters, additional clock cycles are inserted between precharge/active (t_{RP}) commands and active/write (t_{RCD}) commands.

For the definition of timing parameters, see MPDDRC Timing Parameter 0 Register.

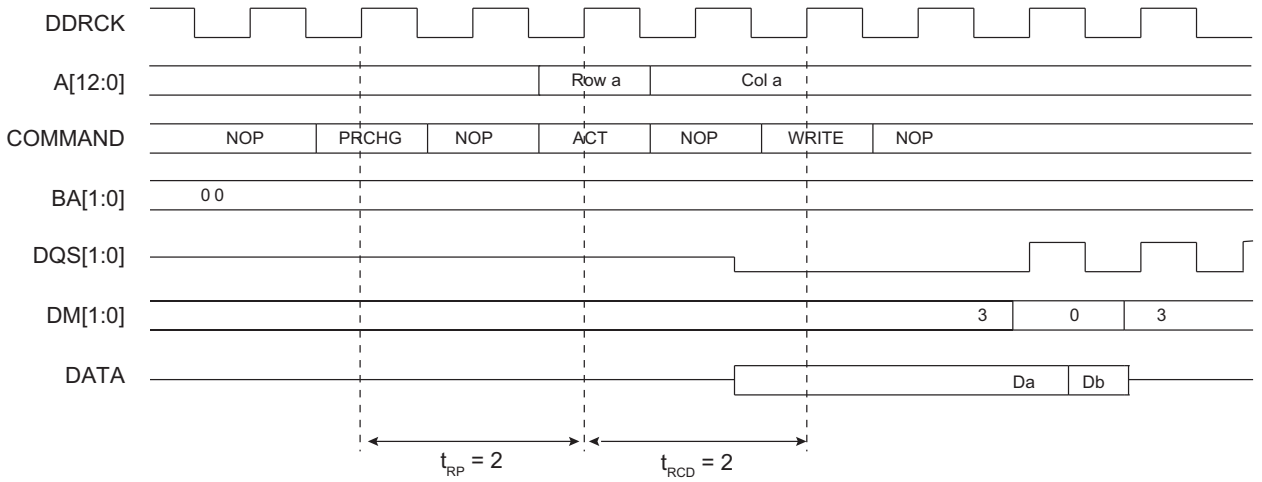
Write accesses to the DDR-SDRAM device are burst oriented and the burst length is programmed to 8. It determines the maximum number of column locations that can be accessed for a given write

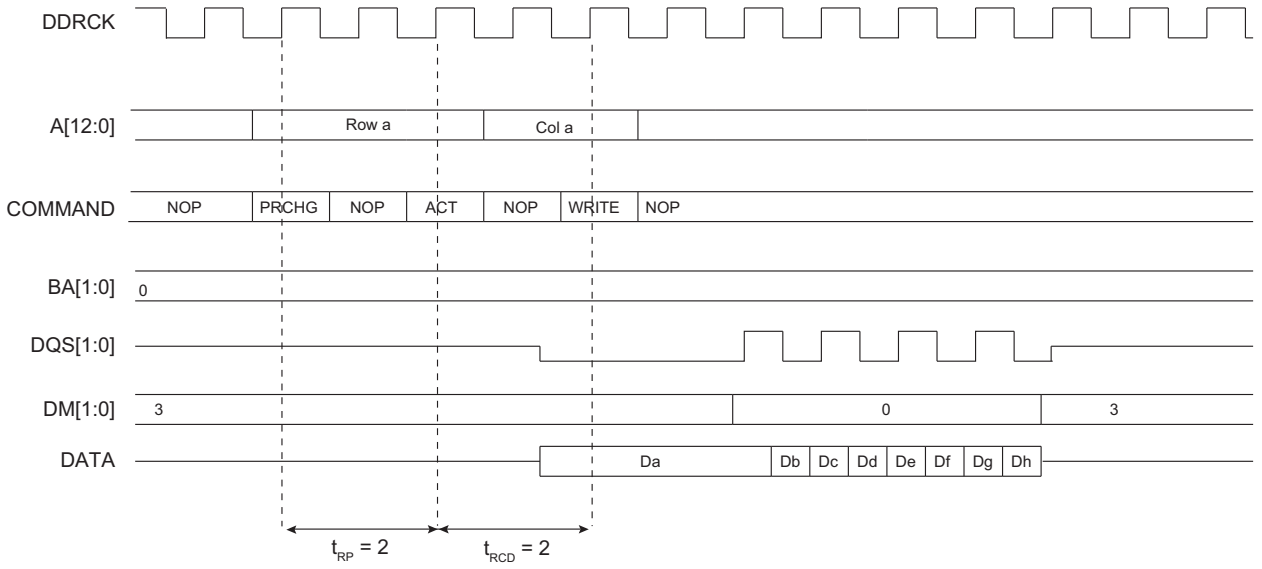
© 2026 Microchip Technology Inc. and its subsidiaries

command. When the write command is issued, eight columns are selected. All accesses for that burst take place within these eight columns, thus the burst wraps within these eight columns if a boundary is reached. These eight columns are selected by addr[13:3]. addr[2:0] is used to select the starting location within the block.

In case of incrementing burst (INCR/INCR4/INCR8/INCR16), the addresses can cross the 16-byte boundary of the DDR-SDRAM device. For example, when a transfer (INCR4) starts at address 0x0C, the next access is 0x10, but since the burst length is programmed to 8, the next access is at 0x00. Since the boundary is reached, the burst is wrapped. The MPDDRC takes this feature of the DDR-SDRAM device into account. In case of a transfer starting at address 0x04/0x08/0x0C or starting at address 0x10/0x14/0x18/0x1C, two write commands are issued to avoid wrapping when the boundary is reached. The last write command is subject to DM input logic level. If DM is registered high, the corresponding data input is ignored and the write access is not done. This avoids additional writing.

Figure 23.2. Single Write Access, Row Closed, DDR2-SDRAM Devices





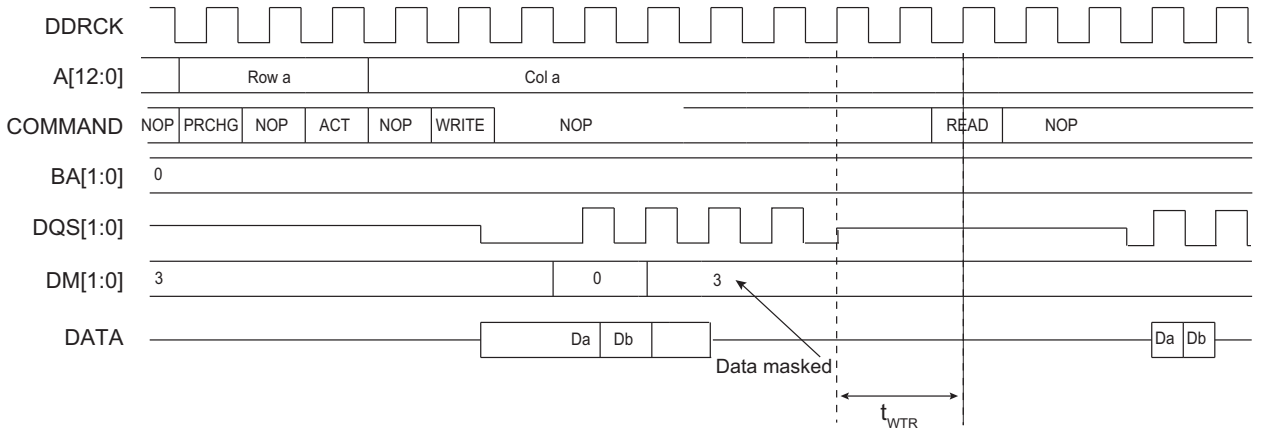


Figure 23.3. Burst Write Access, Row Closed, DDR2-SDRAM Devices

A write command can be followed by a read command. To avoid breaking the current write burst, t_{WTR}/t_{WRD} (bl/2 + 2 = 6 cycles) should be met. See the figure below.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 23.4. Single Write Access Followed by a Read Access, DDR2-SDRAM Devices

23.5.2. DDR-SDRAM Controller Read Cycle

The MPDDRC provides burst access or single access in Normal mode (MPDDRC_MR.MODE = 0). Whatever the access type, the MPDDRC keeps track of the active row in each bank, thus maximizing performance of the MPDDRC.

The DDR-SDRAM devices are programmed with a burst length equal to 8 which determines the length of a sequential data output by the read command that is set to 8. The latency from read command to data output depends on the memory type, as shown in the following table. This value is programmed during the initialization phase (see Product Dependencies, Initialization Sequence).

Table 23.2. CAS Read Latency

Memory Devices	CAS Read Latency
DDR2-SDRAM	3/4
DDR3-SDRAM (DLL Off/DLL On)	5/6

To initiate a single access, the MPDDRC checks if the page access is already open. If row/bank addresses match with the previous row/bank addresses, the controller generates a read command. If the bank addresses are not identical or if bank addresses are identical but the row addresses are not identical, the controller generates a precharge command, activates the new row and initiates a read command. To comply with DDR-SDRAM timing parameters, additional clock cycles are inserted between precharge/active (t_{RP}) commands and active/read (t_{RCD}) commands. After a read command, additional wait states are generated to comply with CAS latency. The MPDDRC supports a CAS latency delay of 3, 4, 5 or 6 clock cycles.

To initiate a burst access, the MPDDRC checks the transfer type signal. If the next accesses are sequential read accesses, reading to the SDRAM device is carried out. If the next access is a read non-sequential access, then an automatic page break can be inserted. If the bank addresses are not identical or if bank addresses are identical but the row addresses are not identical, the controller generates a precharge command, activates the new row and initiates a read command. If page access is already open, a read command is generated.

To comply with DDR-SDRAM timing parameters, additional clock cycles are inserted between precharge/active (t_{RP}) commands and active/read (t_{RCD}) commands. The MPDDRC supports a CAS latency delay of 3, 4, 5 or 6 clock cycles. During this delay, the controller uses internal signals to anticipate the next access and improve the performance of the controller. Depending on the latency, the MPDDRC anticipates 3, 4, 5 or 6 read accesses. In case of burst of specified length, accesses are not anticipated, but if the burst is broken (border, Busy mode, etc.), the next access is treated as an incrementing burst of unspecified length, and depending on the latency, the MPDDRC anticipates 3, 4, 5 or 6 read accesses.

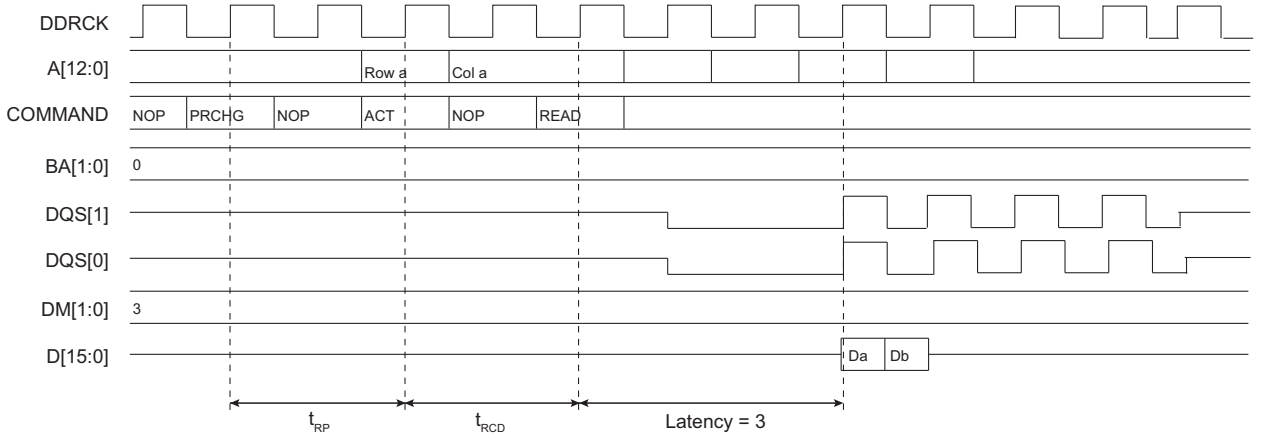
© 2026 Microchip Technology Inc. and its subsidiaries

For the definition of timing parameters, see MPDDRC Configuration Register.

Read accesses to the DDR-SDRAM are burst oriented and the burst length is programmed to 8. The burst length determines the maximum number of column locations that can be accessed for a given read command. When the read command is issued, eight columns are selected. All accesses for that burst take place within these eight columns, meaning that the burst wraps within these eight columns if the boundary is reached. These eight columns are selected by addr[13:3]; addr[2:0] is used to select the starting location within the block.

In case of incrementing burst (INCR/INCR4/INCR8/INCR16), the addresses can cross the 16-byte boundary of the DDR-SDRAM device. For example, when a transfer (INCR4) starts at address 0x0C, the next access is 0x10, but since the burst length is programmed to 8, the next access is 0x00. Since the boundary is reached, the burst wraps. The MPDDRC takes into account this feature of the SDRAM device. In case of the DDR-SDRAM device, transfers start at address 0x04/0x08/0x0C. Two read commands are issued to avoid wrapping when the boundary is reached. The last read command may generate additional reading (1 read cmd = 4 DDR words).

Figure 23.5. Single Read Access, Row Closed, Latency = 3, DDR2-SDRAM Devices



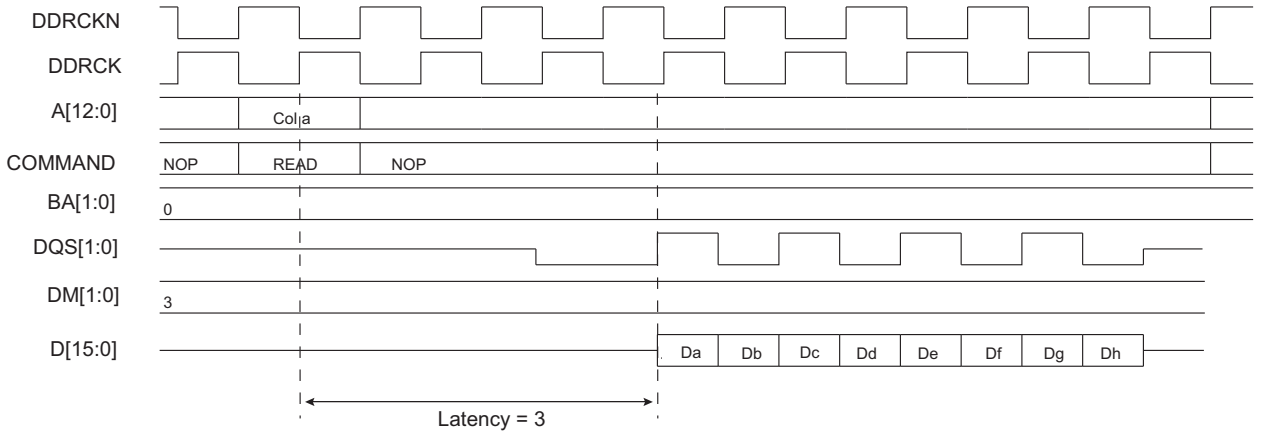


Figure 23.6. Burst Read Access, Latency = 3, DDR2-SDRAM Devices

23.5.3. Refresh (Auto-Refresh Command)

An Auto-refresh command is used to refresh the external SDRAM devices. Refresh addresses are generated internally by the DDR-SDRAM device and incremented automatically after each auto-refresh. The MPDDRC generates these auto-refresh commands periodically. A timer is loaded in the MPDDRC_RTR with the value which indicates the number of clock cycles between refresh cycles (see MPDDRC Refresh Timer Register). When the MPDDRC initiates a refresh of the DDR-SDRAM device,

© 2026 Microchip Technology Inc. and its subsidiaries

internal memory accesses are not delayed. However, if the CPU tries to access the DDR-SDRAM device, the client indicates that the device is busy. A refresh request does not interrupt a burst transfer in progress.

23.5.4. Power Management

23.5.4.1. Self-Refresh Mode

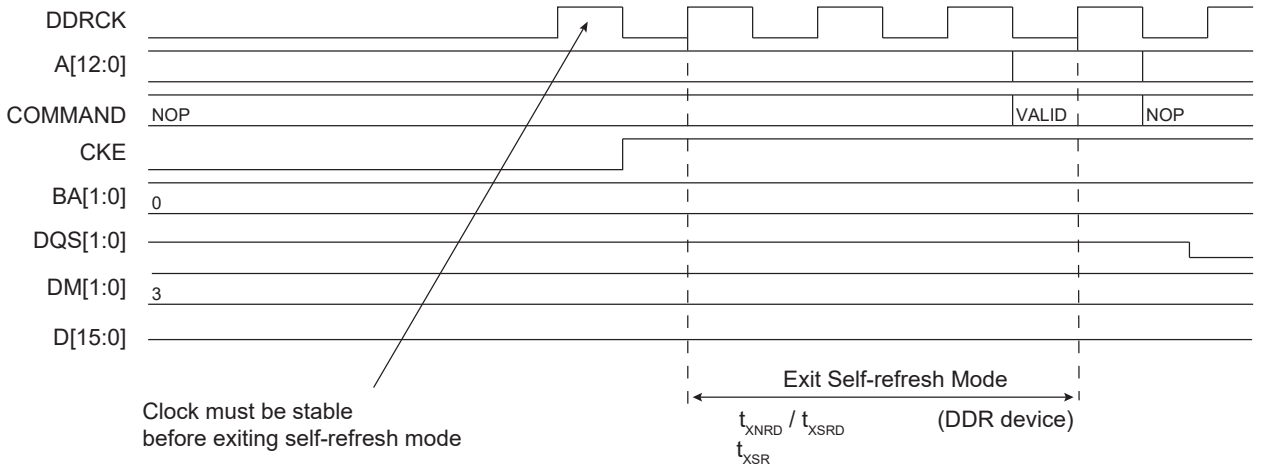
This mode is activated by configuring the Low-power Command bit (LPCB) to 1 in the MPDDRC Low-Power Register (MPDDRC_LPR).

Self-refresh mode is used in Power-down mode, that is, when no access to the DDR-SDRAM device is possible. In this case, power consumption is very low. In Self-refresh mode, the DDR-SDRAM device retains data without external clocking and provides its own internal clocking, thus performing its own auto-refresh cycles. During the self-refresh period, CKE is driven low. As soon as the DDR-SDRAM device is selected, the MPDDRC provides a sequence of commands and exits Self-refresh mode.

The MPDDRC re-enables Self-refresh mode as soon as the DDR-SDRAM device is not selected. It is possible to define when Self-refresh mode is to be enabled by configuring the TIMEOUT field in the MPDDRC_LPR:

0: Self-refresh mode is enabled as soon as the DDR-SDRAM device is not selected.

1: Self-refresh mode is enabled 64 clock cycles after completion of the last access.



2: Self-refresh mode is enabled 128 clock cycles after completion of the last access.

Disabled banks are not refreshed in Self-refresh mode. This feature permits to reduce the self-refresh current.

The DDR2-SDRAM must remain in Self-refresh mode during the minimum of t_{CKE} periods (refer to the memory device data sheet), and may remain in Self-refresh mode for an indefinite period.

The DDR3-SDRAM must remain in Self-refresh mode for the minimum of t_{CKESR} periods (refer to the memory device data sheet) and may remain in Self-refresh mode for an indefinite period.

Figure 23.7. Self-Refresh Mode Exit

23.5.4.2. Power-Down Mode

This mode is activated by configuring the Low-power Command bit (LPCB) to 2 in the MPDDRC Low-Power Register (MPDDRC_LPR).

© 2026 Microchip Technology Inc. and its subsidiaries

Power-down mode is used when no access to the DDR-SDRAM device is possible. In this mode, power consumption is greater than in Self-refresh mode. This state is similar to Normal mode (no Low-power mode/no Self-refresh mode), but the CKE pin is low and the input and output buffers are deactivated as soon the DDR-SDRAM device is no longer accessible. In contrast to Self-refresh mode, the DDR-SDRAM device cannot remain in Low-power mode longer than one refresh period (64 ms/32 ms). As no auto-refresh operations are performed in this mode, the MPDDRC carries out the refresh operation. For DDR-SDRAM devices, a NOP command must be generated for a minimum period defined in the TXP field of MPDDRC_TPR1 (see MPDDRC Timing Parameter 1 Register) and in the TXARD and TXARDS fields of MPDDRC_TPR2 (see MPDDRC Timing Parameter 2 Register) for DDR2_SDRAM devices.

The exit procedure is faster than in Self-refresh mode. See the following figure. The MPDDRC returns to Power-down mode as soon as the DDR-SDRAM device is not selected. It is possible to define when Power-down mode is enabled by configuring the TIMEOUT field in the MPDDRC_LPR:

0: Power-down mode is enabled as soon as the DDR-SDRAM device is not selected.

1: Power-down mode is enabled 64 clock cycles after completion of the last access.

2: Power-down mode is enabled 128 clock cycles after completion of the last access.

23.5.4.3. Change Frequency During Self-Refresh Mode with DDR2-SDRAM and DDR3-SDRAM Devices

To change frequency, Self-refresh mode must be activated. This is done by configuring the Low-power Command bit (LPCB) to 1 and writing a '1' to the Change Frequency Command bit (CHG_FR) in the Low-power register (MPDDRC_LPR).

Once the DDR-SDRAM device is in Self-refresh mode, the user must make sure there is no access in progress. Then, the user can change the clock frequency. The device input clock frequency changes only within minimum and maximum operating frequencies as specified by the DDR2-SDRAM and DDR3-SDRAM providers. The MPDDRC_RTR (COUNT), MPDDRC_CR (CAS, etc.), MPDDRC_TPR0 (TRC, TRP, TRAS, etc.), MPDDRC_TPR1 (TRFC, TXSNR, TXSRD, TXP) and MPDDRC_TPR2 (TRTP, TFAW, etc.) registers can be updated according to the new clock frequency. Once the input clock frequency is changed, new stable clocks must be provided to the device before exiting from Self-refresh mode.

To exit from Self-refresh mode, the DDR-SDRAM device must be selected. The MPDDRC provides a sequence of commands and exits Self-refresh mode.

During a change frequency procedure, MPDDRC_LPR.CHG_FR is set to 0 automatically.

Before changing frequency, make sure the processor clock (PCK) value is twice the system bus clock (MCK) value.

23.5.4.4. DDR3 Device DLL On/Off Switching Procedure

The JEDEC standard allows switching between DLL Off and DLL On modes, and hence beetwen low and high frequencies.

To enable DDR3 DLL Off mode, set MPDDRC_CR.DIS_DLL to 1. To enable DDR3 DLL On mode, set MPDDRC_CR.DIS_DLL to 0 during DDR3-SDRAM initialization.

23.5.4.4.1. DLL On to DLL Off Procedure

To switch from DLL On mode to DLL Off mode, follow the procedure below:

1. Make sure no access is in progress and Self-refresh mode is disabled.
2. Set MPDDRC_CR.DIS_DLL to 1.
3. Enable Self-refresh mode and set MPDDRC_LPR.UPD_MR to 2.
4. Wait until self-refresh is performed, then read MPDDRC_LPR.SELF_DONE.
5. Set MPDDRC_LPR.CHG_FREQ to 1 and MPDDRC_LPR.UPD_MR to 0.
6. Change the frequency. The maximum value is 125 MHz, but some providers allow 200 MHz.

© 2026 Microchip Technology Inc. and its subsidiaries

7. In MPDDRC_CR, update appropriate values: Reset DLL (DLL), CAS read latency (CAS), CAS write latency (CAS_WR). DLL must be set to 0. Update other bit fields depending on the Frequency and DLL Off parameter settings.
8. Update all asynchronous timings (TRAS, TRP, TXSRD, etc.) in MPDDRC_TPR0, MPDDRC_TPR1 and MPDDRC_TPR2 depending on the Frequency and DLL Off parameter settings
9. Perform an access to DRAM.
10. DLL is now disabled.

23.5.4.4.2.DLL Off to DLL On Procedure

To switch from DLL Off mode to DLL On mode, follow the procedure below:

1. Make sure no access is in progress and Self-refresh mode is disabled.
2. Enable Self-refresh mode and set MPDDRC_LPR.CHG_FREQ to 1.
3. Wait until self-refresh is performed, then read MPDDRC_LPR.SELF_DONE.
4. Change the frequency. The minimum value is 303 MHz.
5. In MPDDRC_CR, update appropriate values: Reset DLL (DLL), CAS read latency (CAS), CAS write latency (CAS_WR). DIS_DLL must be set to 0 and DLL must be set to 1. Update other bit fields depending on the Frequency and DLL On parameter settings.
6. Update all asynchronous timings (TRAS, TRP, TXSRD, etc.) in MPDDRC_TPR0, MPDDRC_TPR1 and MPDDRC_TPR2 depending on the Frequency and DLL On parameter settings.
7. Perform an access to DRAM.
8. DLL is now enabled.

23.5.4.5.Reset Mode

The Reset mode is a feature of DDR2-SDRAM. This mode is activated by configuring the Low-power Command bit (LPCB) to 3 and writing a '1' to the Clock Frozen Command bit (CLK_FR) in the Low-power register (MPDDRC_LPR).

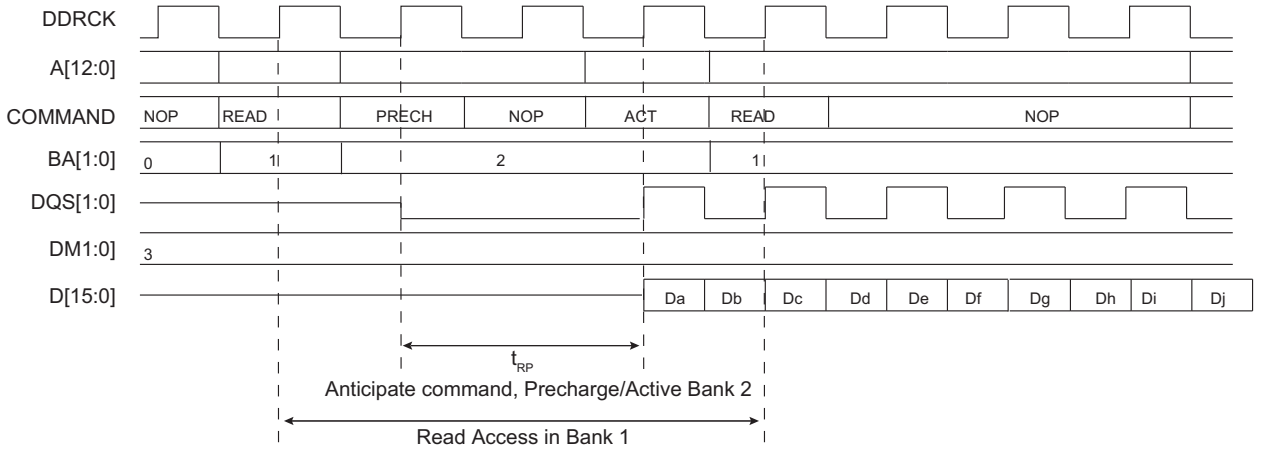
When this mode is enabled, the MPDDRC leaves Normal mode (MPDDRC_MR.MODE = 0) and the controller is frozen. Before enabling this mode, the user must make sure there is no access in progress.

To exit Reset mode, the Low-power Command bit (LPCB) must be configured to 0, the Clock Frozen Command bit (CLK_FR) must be written to '0' and the initialization sequence must be generated by software (see DDR2-SDRAM Initialization).

23.5.5. Optimized Access Functionality

The DDR-SDRAM protocol imposes a check of timings prior to performing a read or a write access, thus decreasing system performance. An access to DDR-SDRAM is performed if banks and rows are open (or active). To activate a row in a particular bank, the last open row must be deactivated and a new row must be open. Two DDR-SDRAM commands must be performed to open a bank: Precharge command and Activate command with respect to T_{RP} timing. Before performing a read or write command, T_{RCD} timing must be checked.

This operation generates a significant bandwidth loss.



The controller is designed to mask these timings and thus improve the system bandwidth.

The MPDDRC is a controller whereby 7 hosts can simultaneously reach the controller. This feature improves the bandwidth of the system because it can detect 7 requests on the system bus client inputs and thus anticipate the commands that follow, Precharge command and Activate command in bank X during the current access in bank Y. This masks t_{RP} and t_{RCD} timings (see the following figure). In the best case, all accesses are done as if the banks and rows were already open. The best condition is met when the 7 hosts work in different banks. In the case of 7 simultaneous read accesses, when the four or eight banks and associated rows are open, the controller reads with a

© 2026 Microchip Technology Inc. and its subsidiaries

continuous flow and masks the CAS latency for each access. To allow a continuous flow, the read command must be set at 3, 4, 5 or 6 cycles (CAS latency) before the end of the current access. The arbitration scheme must be changed since the round-robin arbitration cannot be respected. If the controller anticipates a read access, and thus a host with a high priority arises before the end of the current access, then this host will not be serviced.

Figure 23.8. Anticipate Precharge/Activate Command in Bank 2 during Read Access in Bank 1

MPDDRC embeds three arbitration mechanisms based on round-robin arbitration which allows to share the external device between different hosts when two or more hosts try to access the DDR-SDRAM device at the same time.

The three arbitration types are round-robin arbitration and two weighted round-robin arbitrations. For weighted round-robin arbitrations, the priority can be given either depending on the number of requests or words per port, or depending on the required bandwidth per port. The type of arbitration can be chosen by setting the ARB field in the Configuration Arbiter register (MPDDRC_CONF_ARBITER) (see MPDDRC Configuration Arbiter Register).

23.5.5.1. Round-robin Arbitration

Round-robin arbitration is used when the ARB field is set to 0 (see MPDDRC Configuration Arbiter Register). This algorithm dispatches the requests from different hosts to the DDR-SDRAM device in a round-robin manner. If two or more host requests arise at the same time, the host with the lowest number is serviced first, then the others are serviced in a round-robin manner.

To avoid burst breaking and to provide the maximum throughput for the DDR-SDRAM device, arbitration must only take place during the following cycles:

1. Idle cycles: when no host is connected to the DDR-SDRAM device.
2. Single cycles: when a client is currently doing a single access.
3. End of Burst cycles: when the current cycle is the last cycle of a burst transfer:
   - For bursts of defined length, predicted end of burst matches the size of the transfer.
   - For bursts of undefined length, predicted end of burst is generated at the end of each four-beat boundary inside the INCR transfer.
4. Anticipated Access: when an anticipated read access is done while the current access is not complete, the arbitration scheme can be changed if the anticipated access is not the next access serviced by the arbitration scheme.

23.5.5.2. Request-word Weighted Round-robin Arbitration

In request-word weighted round-robin arbitration, the weight is the number of requests or the number of words per port.

© 2026 Microchip Technology Inc. and its subsidiaries

This arbitration scheme is enabled by configuring the ARB field to 1 (see MPDDRC Configuration Arbiter Register). This algorithm grants a port for X[1] consecutive first transfer (htrans = NON SEQUENTIAL) of a burst or X single transfer, or for X word transfers. It is possible to choose between an arbitration scheme by request or by word per port by setting the RQ_WD_Px field (see MPDDRC Configuration Arbiter Register).

Note: 1. X is an integer value provided by some host modules to the arbiter.

It is also possible for the user to provide the number of requests or words (by overwriting the information provided by a host) on host basis by configuring the MA_PR_Px field. Depending on the application, the number of these requests or words can be reduced or increased using the NRD_NWD_BDW_Px fields (see MPDDRC Configuration Arbiter Register).

The TIMEOUT_Px field defines the delay between two accesses on the same port in number of cycles before rearbitrating the access to another port. This field avoids a timeout on the system, as some hosts add idle cycles between two consecutive accesses (see MPDDRC Configuration Arbiter Register).

This algorithm dispatches the requests from different hosts to the DDR-SDRAM device in a round-robin manner. If two or more host requests arise at the same time, the host with the lowest number is serviced first, then the others are serviced in a round-robin manner when the number of requests or words is reached or when the timeout value is reached.

To avoid burst breaking and to provide the maximum throughput for the DDR-SDRAM device, arbitration must only take place during the following cycles:

1. Timeout is reached: the delay between two accesses is equal to TIMEOUT_Px.
2. The number of requests or words is reached: when the current cycle is the last cycle of a transfer.

23.5.5.3. Bandwidth Weighted Round-robin Arbitration

In bandwidth weighted round-robin arbitration, a minimum bandwidth is guaranteed per port.

This arbitration scheme is enabled when the ARB field is set to 2 (see MPDDRC Configuration Arbiter Register).

This algorithm grants to each port a percentage of the bandwidth. The NRD_NWD_BDW_Px field defines the percentage allocated to each port.

The percentage of the bandwidth is programmed with the NRD_NWD_BDW_Px fields (see MPDDRC Configuration Arbiter Register).

The TIMEOUT_Px field defines the delay between two accesses on the same port in number of cycles rearbitrating the access to another port. This field avoids a timeout on the system, as some hosts add idle cycles between two consecutive accesses (see MPDDRC Configuration Arbiter Register).

This algorithm dispatches the requests from different hosts to the DDR-SDRAM device in a round-robin manner. If two or more host requests arise at the same time, the host with the lowest number is serviced first, then the others are serviced in a round-robin manner when the allocated bandwidth is reached or when the timeout value is reached.

The BDW_BURST field allows to arbitrate either when the current host reaches exactly the programmed bandwidth, or when the current host reaches exactly the programmed bandwidth and the current access is ended (see MPDDRC Configuration Arbiter Register).

To provide the maximum throughput for the DDR-SDRAM device, arbitration must only take place during the following cycles:

1. Timeout is reached: the delay between two accesses is equal to TIMEOUT_Px.
2. The allocated bandwidth is reached although the current cycle is not ended.
3. The allocated bandwidth is reached and the current cycle is the last cycle of a transfer.

© 2026 Microchip Technology Inc. and its subsidiaries

23.5.5.4. Quality Of Service Arbitration

This arbitration scheme is enabled when the ARB field is set to 3 (see MPDDRC Configuration Arbiter Register).

The arbitration scheme is organized in priority pools corresponding each to an access criticality class as shown in the corresponding Latency Quality of Service column in the following table. When the Latency Quality of Service is enabled for a host-client pair through the system bus matrix (refer to the section "Bus Matrix (MATRIX)"), the priority pool number to use for arbitration at the client port is determined from the host. When the Latency Quality of Service is disabled, it is determined through the system bus matrix user interface. Refer to “MATRIX Priority Register A For Clients” in the section "Bus Matrix (MATRIX)".

Table 23.3. Arbitration Priority Pools

Priority pool	Latency Quality of Service
3	Latency Critical
2	Latency Sensitive
1	Bandwidth Sensitive
0	Background Transfers

Round-robin priority is used in the highest and lowest priority pools 3 and 0, whereas fixed level priority is used between priority pools and in the intermediate priority pools 2 and 1.

For each client, each host is assigned to one of the client priority pools based on the Latency Quality of Service inputs or to the priority registers for clients (MxPR fields of MATRIX_PRAS and MATRIX_PRBS, refer to the section "Bus Matrix (MATRIX)"). When evaluating host requests, this priority pool level always takes precedence.

After reset, most of the hosts belong to the lowest priority pool (MxPR = 0, Background Transfer) and are therefore granted bus access in a true round-robin order.

The highest priority pool must be specifically reserved for hosts requiring very low access latency. If more than one host belong to this pool, those hosts are granted bus access in a biased round-robin manner which enables tight and deterministic maximum access latency from system bus requests. In the worst case, any currently occurring high-priority host request is granted after the current bus host access has ended and any other high priority pool host requests have been granted once each.

The lowest priority pool shares the remaining bus bandwidth between system bus hosts.

Intermediate priority pools enable fine priority tuning. Typically, a latency-sensitive host or a bandwidth-sensitive host uses such a priority level. The higher the priority level (MxPR value, refer to the section "Bus Matrix (MATRIX)"), the higher the host priority.

All combinations of MxPR values are allowed for all hosts and clients. For example, some hosts might be assigned the highest priority pool (round-robin), and remaining hosts the lowest priority pool (round-robin), with no host for intermediate fixed priority levels.

Some hosts, such as LCD or DMA, drive a signal named HNBREQ on the system bus to indicate the number of transfers to be performed. When the field MPDDRC_CONF_ARBITER.KEEP_LAYER is set to 1, the host with the highest LQOS value and a HNBREQ value different from 0 continues to be granted, even during a last data phase with IDLE cycles.

23.5.6. Scrambling/Unscrambling Function

The external data bus can be scrambled in order to prevent intellectual property data located in off-chip memories from being easily recovered by analyzing data at the package pin level of either the microcontroller or the memory device.

The scrambling and unscrambling are performed on-the-fly without additional wait states.

© 2026 Microchip Technology Inc. and its subsidiaries

The scrambling method depends on two user-configurable key registers, KEY1 in the "MPDDRC OCMS KEY1 Register" and KEY2 in the "MPDDRC OCMS KEY2 Register". These key registers are only accessible in Write mode.

The key must be securely stored in a reliable non-volatile memory in order to recover data from the off-chip memory. Any data scrambled with a given key cannot be recovered if the key is lost.

The scrambling/unscrambling function can be enabled or disabled by programming the "MPDDRC OCMS Register".

23.5.7. Clearing Scrambling Keys on Tamper Event

On tamper detection event on WKUP pins, it is possible to perform an immediate clear of the scrambling keys (MPDDRC_OCMS_KEY1 and MPDDRC_OCMS_KEY2) if bit MPDDRC_OCMS.TAMPCLR = 1.

23.5.8. Register Write Protection

To prevent any single software error from corrupting MPDDRC behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the MPDDRC Write Protection Mode Register (MPDDRC_WPMR).

If a write access to a write-protected register is detected, the WPVS flag in the MPDDRC Write Protection Status Register (MPDDRC_WPSR) is set and the field WPVSRC indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading MPDDRC_WPSR.

The following registers are write-protected when the bit WPEN is set:

- MPDDRC Mode Register
- MPDDRC Refresh Timer Register
- MPDDRC Configuration Register
- MPDDRC Timing Parameter 0 Register
- MPDDRC Timing Parameter 1 Register
- MPDDRC Memory Device Register
- MPDDRC OCMS Register
- MPDDRC OCMS KEY1 Register
- MPDDRC OCMS KEY2 Register

The following registers are write-protected when the bit WPITEN is set:

- MPDDRC Interrupt Enable Register
- MPDDRC Interrupt Disable Register

23.5.9. Bus Monitor, Performance Monitor

The MPDDRC embeds a bus monitor which collects bus transaction information from 7 MPDDRC ports. This information, such as accumulated latency (MPDDRC_MINFOx (TOTAL_LATENCY)) or number of transfers (MPDDRC_MINFOx (NB_TRANSFERS)), can be used to calculate the latency and bandwidth for each port by using a metric counter.

The following metrics are computed for each port within a configurable address range:

- Total number of write transfers
- Total number of read transfers
- Total number of read/write transfers
- Total read latencies

© 2026 Microchip Technology Inc. and its subsidiaries

- Total write latencies
- Total write/read latencies
- Maximum latencies per port
- Total number of cycles
- Total latency vs QoS value

The Monitor Configuration (MPDDRC_MCFGR) and Monitor Address High/Low Port x (MPDDRC_MADDRx) registers define the type of transaction collected (read, write or read/write) and the address range to monitor.

MPDDRC address mapping is from 0x2000_0000 to 0x2FFF_FFFF. To define the address range analyzed by the monitor, the address bits [27:13] are used to configure the lower and upper bounds. The lower bound can be modified by writing the field MPDDRC_MADDRx.ADDR_LOW_PORTx. The upper bound can be modified by writing the field MPDDRC_MADDRx.ADDR_HIGH_PORTx. The minimum range that can be analyzed is 8 Kbytes.

By default, the monitor is enabled and the address range is 0x2000_0000 to 0x2FFF_FFFF.

Monitor use example:

1. Clear the configuration register: write 0x00000000 in MPDDRRC_MCFGR.
2. Enable the monitor: write 0x00000001 in MPDDRRC_MCFGR.
3. Reset the monitor: write 0x00000003 in MPDDRRC_MCFGR.
4. Enable the monitor: write 0x00000001 in MPDDRRC_MCFGR.
5. Define the address range in MPDDRC_MADDRx or use the default value.
6. Start monitoring: write 0x00000011 in MPDDRRC_MCFGR.
7. Monitoring is launched. An event can be used to stop monitoring.
8. Stop profiling: write 0x00000001 in MPDDRRC_MCFGR.
9. To know the number of tranfers per port, write 0x00000801 in MPDDRRC_MCFGR and read MPDDRC_MINFOx (NB_TRANSFERS).
10. To know the total number of cycles while monitoring is in progress, write 0x0003001 in MPDDRRC_MCFGR and read MPDDRC_MINFOx (TOTAL_CYCLE_COUNT).

Use the following formulas to compute the latency and bandwidth for each port (in percent):

- Latency:
  (Px_TOTAL_LATENCY/TOTAL_CYCLE_COUNT) *100
- Bandwidth:
  (Px_TOTAL_Px_NB_TRANSFERS/TOTAL_CYCLE_COUNT) *100

23.5.10. Security and Safety Analysis and Reports

Several types of checks are performed when the MPDDRC is accessing the memory device.

The registers listed below are monitored with a single error checker and, in case of a single error event, the error is reported in MPDDRC_WPSR.SEQE:

- Mode register (MPDDRC_MR)
- Memory Device register (MPDDRC_MD
- Refresh Timer register (MPDDRC_RTR)
- Timing Parameter 0/1/2 registers (MPDDRC_TPR0/1/2)
- Low-Power register (MPDDRC_LPR)
- Configuration register (MPDDRC_CR)

© 2026 Microchip Technology Inc. and its subsidiaries

- OCMS KEY1 register (MPDDRC_OCMS_KEY1)
- OCMS KEY2 register (MPDDRC_OCMS_KEY2)

The peripheral clock of the MPDDRC is monitored by specific circuitry to detect abnormal waveforms on the internal clock net that may affect the behavior of the MPDDRC. Corruption on the triggering edge of the clock or a pulse with a minimum duration may be identified. If the flag MPDDRC_WPSR.CGD is set, an abnormal condition occurred on the peripheral clock. This flag is not set under normal operating conditions.

The internal sequencer of the MPDDRC is also monitored and if an abnormal state is detected, the flag MPDDRC_WPSR.SEQE is set. This flag is not set under normal operating conditions.

If the flag MPDDRC_WPSR.CGD = 1, a clock glitch has been detected. This flag is not set under normal operating conditions.

The software accesses to the MPDDRC are monitored and if an incorrect access is performed, the flag MPDDRC_WPSR.SWE is set. The type of incorrect/abnormal software access is reported in the MPDDRC_WPSR.SWETYP field (see MPDDRC Write Protection Status Register (MPDDRC_WPSR) for details), e.g., writing a new configuration (MPDDRC_CR, MPDDRC_TPR0/1/2, MPDDRC_MD, MPDDRC_OCMS, MPDDRC_OCMS_KEY1/2) after the initialization of the MPDDRC (i.e., if MPDDRC_TR.COUNT > 0) is an error. MPDDRC_WPSR.ECLASS is an indicator reporting the criticality of the SWETYP report.

The flags CGD, SEQE, SWE and WPVS are automatically cleared when MPDDRC_WPSR is read.

If one of these flags is set, the flag MPDDRC_ISR.SECE is set and can trigger an interrupt if the MPDDRC_IMR.SECE bit is ‘1’. SECE is cleared by reading MPDDRC_ISR.

The MPDDRC embeds an automatic periodic check of an address of the memory device. This function can be enabled by writing a 1 to the MPDDRC_SAFETY.EN bit. The address to be checked can be configured by writing the field MPDDRC_SAFETY.ADDRESS. When MPDDRC_SAFETY.EN = 1, the MPDDRC performs read and write accesses with specific, predetermined, data patterns to the configured address, with no impact for the application software.

MPDDRC_SAFETY.EN must be set immediately after the initialization sequence.

23.6. Software Interface/SDRAM Organization, Address Mapping

The DDR-SDRAM address space is organized into banks, rows and columns. The MPDDRC maps different memory types depending on values set in the Configuration register (MPDDRC_CR) (see MPDDRC Configuration Register). The tables that follow illustrate the relation between CPU addresses and columns, rows and banks addresses for 16-bit memory data bus widths.

The MPDDRC supports address mapping in Linear mode.

Sequential mode is a method for address mapping where banks alternate at each last DDR-SDRAM page of the current bank.

Interleaved mode is a method for address mapping where banks alternate at each DDR-SDRAM end of page of the current bank.

The MPDDRC makes the DDR-SDRAM device access protocol transparent to the user. The tables that follow illustrate the DDR-SDRAM device memory mapping seen by the user in correlation with the device structure. Various configurations are illustrated.

23.7.1. MPDDRC Mode Register

Name: MPDDRC_MR
Offset: 0x00
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the MPDDRC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						MODE[2:0]		
Access						R/W	R/W	R/W
Reset						0	0	0

Bits 2:0 – MODE[2:0] MPDDRC Command Mode
This field defines the command issued by the MPDDRC when the SDRAM device is accessed. This register is used to initialize the SDRAM device and to activate Deep Power-down mode.

Value	Name	Description
0	NORMAL_CMD	Normal Mode. Any access to the MPDDRC is decoded normally. To activate this mode, the command must be followed by a write to the DDR-SDRAM.
1	NOP_CMD	The MPDDRC issues a NOP command when the DDR-SDRAM device is accessed regardless of the cycle. To activate this mode, the command must be followed by a write to the DDR-SDRAM.
2	PRCGALL_CMD	The MPDDRC issues the All Banks Pre-charge command when the DDR-SDRAM device is accessed regardless of the cycle. To activate this mode, the command must be followed by a write to the SDRAM.
3	LMR_CMD	The MPDDRC issues a Load Mode Register command when the DDR-SDRAM device is accessed regardless of the cycle. To activate this mode, the command must be followed by a write to the DDR-SDRAM.
4	RFSH_CMD	The MPDDRC issues an Auto-refresh command when the DDR-SDRAM device is accessed regardless of the cycle. Previously, an All Banks Pre-charge command must be issued. To activate this mode, the command must be followed by a write to the DDR-SDRAM.
5	EXT_LMR_CMD	The MPDDRC issues an Extended Load Mode Register command when the SDRAM device is accessed regardless of the cycle. To activate this mode, the command must be followed by a write to the DDR-SDRAM. The write in the DDR-SDRAM must be done in the appropriate bank.
6	CALIB_CMD	Calibration command: to calibrate RTT and RON values for the Process Voltage Temperature (PVT) (DDR3-SDRAM device)

23.7.2. MPDDRC Refresh Timer Register

Name: MPDDRC_RTR
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the MPDDRC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
					COUNT[11:8]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
	COUNT[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 11:0 – COUNT[11:0] MPDDRC Refresh Timer Count

This 12-bit field is loaded into a timer which generates the refresh pulse. Each time the refresh pulse is generated, a refresh sequence is initiated.

The SDRAM requires auto-refresh cycles at an average periodic interval of T_{refi}. The value to be loaded depends on the MPDDRC clock frequency MCK (main system bus clock) and average periodic interval of T_{refi}.

For example, for an SDRAM with T_{refi} = 7.8 µs and a 133 MHz (7.5 ns) main system bus clock, the value of the COUNT field is configured: $((7.8 \times 10^{-6}) / (7.5 \times 10^{-9})) = 1040$ or 0x0410.

23.7.3. MPDDRC Configuration Register

Name: MPDDRC_CR
Offset: 0x08
Reset: 0x00207024
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the MPDDRC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
				CAS_WR[2:0]				
Access				R/W	R/W	R/W		
Reset				0	0	0		

Bit	23	22	21	20	19	18	17	16
	UNAL	DECOD	NDQS	NB				DQMS
Access	R/W	R/W	R/W	R/W				R/W
Reset	0	0	1	0				0

Bit	15	14	13	12	11	10	9	8
	SUP_DDR3	OCD[2:0]					DIS_DLL	DIC_DS
Access	R/W	R/W	R/W	R/W			R/W	R/W
Reset	0	1	1	1			0	0

Bit	7	6	5	4	3	2	1	0
	DLL	CAS[2:0]			NR[1:0]		NC[1:0]	
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	1	0	0	1	0	0

Bits 28:26 – CAS_WR[2:0] CAS Write Latency
This field is unique to DDR3-SDRAM.

Value	Name	Description
5	DDR3_CAS5	DDR3 CAS write latency 5, DLL must be enabled, DLL On mode
6	DDR3_CAS6	DDR3 CAS write latency 6, DLL enabled or not, DLL On/Off mode

Bit 23 – UNAL This bit must always be written to 1.

Bit 22 – DECOD Type of Decoding

Value	Name	Description
0	SEQUENTIAL	Method for address mapping where banks alternate at each last DDR-SDRAM page of the current bank.
1	INTERLEAVED	Method for address mapping where banks alternate at each DDR-SDRAM end of page of the current bank.

Bit 21 – NDQS Not DQS.
This bit is found in DDR2-SDRAM devices, in Extended Mode register 1. DQS may be used in Single-ended mode or paired with optional complementary signal NDQS.

Value	Name	Description
0	ENABLED	'Not DQS' is enabled.
1	DISABLED	'Not DQS' is disabled.

Bit 20 – NB Number of Banks

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
0	4_BANKS	4-bank memory devices
1	8_BANKS	8 banks. Only possible when using DDR2-SDRAM,, DDR3-SDRAM devices.

Bit 16 – DQMS Mask Data is Shared

Value	Name	Description
0	NOT_SHARED	DQM is not shared with another controller
1	SHARED	DQM is shared with another controller

Bit 15 – SUP_DDR3 Supply DDR3-SDRAM or DDR3L-SDRAM
This value is used during the power-up sequence.

Value	Description
0	1.35V DDR3L-SDRAM is used.
7	1.5V DDR3-SDRAM is used.

Bits 14:12 – OCD[2:0] Off-chip Driver
SDRAM Controller supports only two values for OCD (default calibration and exit from calibration). These values MUST always be programmed during the initialization sequence. The default calibration must be programmed first, after which the exit calibration and maintain settings must be programmed.
This field is found only in the DDR2-SDRAM devices.

Value	Name	Description
0	DDR2_EXITCALIB	Exit from OCD Calibration mode and maintain settings
7	DDR2_DEFAULT_CALIB	OCD calibration default

Bit 9 – DIS_DLL Disable DLL
This value is used during the power-up sequence. It is only found in DDR2-SDRAM devices and DDR3-SDRAM devices.

Value	Description
0	Enable DLL.
1	Disable DLL.

Bit 8 – DIC_DS Output Driver Impedance Control (Drive Strength)
This bit name is described as “DS” in some memory data sheets. It defines the output drive strength. This value is used during the power-up sequence.
For DDR3-SDRAM devices, this field is equivalent to ODS, Output Drive Strength.
This bit is found only in DDR2-SDRAM devices and DDR3-SDRAM devices.

Value	Name	Description
0	DDR2_NORMALSTRENGTH_DDR3_RZQ_6	Normal drive strength (DDR2) - RZQ_6 (40 [NOM], DDR3)
1	DDR2_WEAKSTRENGTH_DDR3_RZQ_7	Weak drive strength (DDR2) - RZQ_7 (34 [NOM], DDR3)

Bit 7 – DLL Reset DLL
This bit defines the value of Reset DLL. It is found only in DDR2-SDRAM and DDR3-SDRAM devices. This value is used during the power-up sequence.

Value	Name	Description
0	RESET_DISABLED	Disable DLL reset
1	RESET_ENABLED	Enable DLL reset

Bits 6:4 – CAS[2:0] CAS Latency

Value	Name	Description
3	DDR_CAS3	DDR2 CAS Latency 3

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
4	DDR_CAS4	DDR2 CAS Latency 4
5	DDR_CAS5	DDR2/DDR3 CAS Latency 5
6	DDR_CAS6	DDR3 CAS Latency 6

Bits 3:2 – NR[1:0] Number of Row Bits

Value	Name	Description
0	11_ROW_BITS	11 bits to define the row number, up to 2048 rows
1	12_ROW_BITS	12 bits to define the row number, up to 4096 rows
2	13_ROW_BITS	13 bits to define the row number, up to 8192 rows
3	14_ROW_BITS	14 bits to define the row number, up to 16384 rows

Bits 1:0 – NC[1:0] Number of Column Bits

Value	Name	Description
0	9_COL_BITS	9 bits to define the column number, up to 512 columns, for DDR2/DDR3-SDRAM
1	10_COL_BITS	10 bits to define the column number, up to 1024 columns, for DDR2/DDR3-SDRAM
2	11_COL_BITS	11 bits to define the column number, up to 2048 columns, for DDR2/DDR3-SDRAM
3	12_COL_BITS	12 bits to define the column number, up to 4096 columns, for DDR2/DDR3-SDRAM

23.7.4. MPDDRC Timing Parameter 0 Register

Name: MPDDRC_TPR0
Offset: 0x0C
Reset: 0x20227225
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the MPDDRC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	TMRD[3:0]					TWTR[2:0]		
Access	R/W	R/W	R/W	R/W		R/W	R/W	R/W
Reset	0	0	1	0		0	0	0

Bit	23	22	21	20	19	18	17	16
	TRRD[3:0]				TRP[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	1	0	0	0	1	0

Bit	15	14	13	12	11	10	9	8
	TRC[3:0]				TWR[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	1	1	1	0	0	1	0

Bit	7	6	5	4	3	2	1	0
	TRCD[3:0]				TRAS[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	1	0	0	1	0	1

Bits 31:28 – TMRD[3:0] Load Mode Register Command to Activate or Refresh Command
This field defines the delay between a Load mode register command and an Activate or Refresh command in number of DDRCK clock cycles. The number of cycles is between 0 and 15.

Bits 26:24 – TWTR[2:0] Internal Write to Read Delay
This field defines the internal Write to Read command time in number of DDRCK clock cycles. The number of cycles is between 1 and 7.

Bits 23:20 – TRRD[3:0] Active BankA to Active BankB
This field defines the delay between an Activate command in BankA and an Activate command in BankB in number of DDRCK clock cycles. The number of cycles is between 1 and 15.

Bits 19:16 – TRP[3:0] Row Precharge Delay
This field defines the delay between a Precharge command and another command in number of DDRCK clock cycles. The number of cycles is between 0 and 15.

Bits 15:12 – TRC[3:0] Row Cycle Delay
This field defines the delay between an Activate command and a Refresh command in number of DDRCK clock cycles. The number of cycles is between 0 and 15. When TRC is greater than or equal to 60 ns, the maximum supported frequency is 250 MHz. When the frequency is higher than 200 MHz, an offset of one is added automatically. In such case, TRC must be set to 15 to match the value imposed by DDR-SDRAM devices. If the frequency is higher than 200 MHz, the CAS latency must be set higher than 3 (see “CAS: CAS Latency” in MPDDRC_CR).

© 2026 Microchip Technology Inc. and its subsidiaries

Bits 11:8 – TWR[3:0] Write Recovery Delay
This field defines the Write Recovery Time in number of DDRCK clock cycles. The number of cycles is between 1 and 15.

Bits 7:4 – TRCD[3:0] Row to Column Delay
This field defines the delay between an Activate command and a Read/Write command in number of DDRCK clock cycles. The number of cycles is between 0 and 15.

Bits 3:0 – TRAS[3:0] Active to Precharge Delay
This field defines the delay between an Activate command and a Precharge command in number of DDRCK clock cycles. The number of cycles is between 0 and 15.

Bits 27:24 – TXP[3:0] Exit Power-down Delay to First Command
This field defines the delay between CKE set high and a valid command in number of DDRCK clock cycles. The number of cycles is between 0 and 15.

Bits 23:16 – TXSRD[7:0] Exit Self-refresh Delay to Read Command
This field defines the delay between CKE set high and a Read command in number of DDRCK clock cycles. The number of cycles is between 0 and 255.
This field is found only in DDR2-SDRAM and DDR3-SDRAM devices.
In case of DDR3-SDRAM, this field is equivalent to t_{XSDLL}. In DLL Off mode, this timing is not used. The field must be set to 0.

Bits 15:8 – TXSNR[7:0] Exit Self-refresh Delay to Non-Read Command
This field defines the delay between CKE set high and a Non Read command in number of DDRCK clock cycles. The number of cycles is between 0 and 255. This field is used by the DDR-SDRAM devices. In case of DDR3-SDRAM, this field is equivalent to t_{XS}.

Bits 6:0 – TRFC[6:0] Row Refresh Cycle
This field defines the delay between a Refresh command or a Refresh and Activate command in number of DDRCK clock cycles. The number of cycles is between 0 and 127.

Bits 23:20 – TMOD[3:0] Mode Register Set Command Update Delay
Defines the delay between a Mode Register Set command and another command in terms of number of DDRCK clock cycles. The number of cycles is between 0 and 15. This field is found only on DDR3-SDRAM devices.

Bits 19:16 – TFAW[3:0] Four Active Windows
DDR2 and DDR3 devices with eight banks (1 Gbit or larger) have an additional requirement concerning t_{FAW} timing. This requires that no more than four Activate commands may be issued in any given t_{FAW} (MIN) period.
The number of cycles is between 0 and 15.
This field is found only in DDR2-SDRAM and DDR3-SDRAM devices.

Bits 14:12 – TRTP[2:0] Read to Precharge
Defines the delay between a Read command and a Precharge command in number of DDRCK clock cycles.
The number of cycles is between 0 and 7.

Bits 11:8 – TRPA[3:0] Row Precharge All Delay
Defines the delay between a Precharge All Banks command and another command in number of DDRCK clock cycles. The number of cycles is between 0 and 15.
This field is found only in the DDR2-SDRAM devices.

Bits 7:4 – TXARDS[3:0] Exit Active Power Down Delay to Read Command in Mode “Slow Exit”
Defines the delay between CKE set high and a Read command in number of DDRCK clock cycles. The number of cycles is between 0 and 15.
This field is found only in the DDR2-SDRAM devices.

© 2026 Microchip Technology Inc. and its subsidiaries

Bits 3:0 – TXARD[3:0] Exit Active Power Down Delay to Read Command in Mode “Fast Exit”
Defines the delay between CKE set high and a Read command in number of DDRCK clock cycles. The number of cycles is between 0 and 15.
This field is found only in the DDR2-SDRAM devices.

23.7.7. MPDDRC Low-Power Register

Name: MPDDRC_LPR
Offset: 0x1C
Reset: 0x00010000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
						DISTOEN_DONE	SELF_DONE	CHG_FRQ
Access						R	R	R/W
Reset						0	0	0

Bit	23	22	21	20	19	18	17	16
			UPD_MR[1:0]				ASR	APDE
Access			R/W	R/W			R/W	R/W
Reset			0	0			0	1

Bit	15	14	13	12	11	10	9	8
	SRT	SELFAUTO	TIMEOUT[1:0]					
Access	R/W	R/W	R/W	R/W				
Reset	0	0	0	0				

Bit	7	6	5	4	3	2	1	0
						CLK_FR	LPCB[1:0]	
Access						R/W	R/W	R/W
Reset						0	0	0

Bit 26 – DISTOEN_DONE DLL Disabled to DLL Enabled is Done
Indicates that the DLL Off (disabled) to DLL On (enabled) switching procedure is completed.

Bit 25 – SELF_DONE Self-Refresh is Done
Indicates that external device is in Self-refresh mode.

Bit 24 – CHG_FRQ Change Clock Frequency During Self-Refresh Mode
This mode is used to change the DDR2-SDRAM or DDR3-SDRAM input clock frequency. This mode is unique to the DDR2-SDRAM and DDR3-SDRAM devices.

Bits 21:20 – UPD_MR[1:0] Update Load Mode Register and Extended Mode Register
Used to enable or disable automatic update of the Load Mode register and Extended Mode register. This update depends on the MPDDRC integration in a system. The MPDDRC can either share or not an external bus with another controller.

Value	Name	Description
0	NO_UPDATE	Update of Load Mode and Extended Mode registers is disabled.
1	UPDATE_SHAREDBUS	The MPDDRC shares an external bus. Automatic update is done during a refresh command and a pending read or write access in the SDRAM device.
2	UPDATE_NOSHAREDBUS	The MPDDRC does not share an external bus. Automatic update is done before entering Self-refresh mode.
3	–	Reserved

Bit 17 – ASR Auto Self-Refresh
This mode is unique to DDR3-SDRAM devices supporting an extended temperature range. In this mode, SRT must be disabled.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	DRAM manages Self-refresh entry in either the normal or extended temperature range. In this mode, DRAM manages Self-refresh power consumption when operating conditions change - lower at low temperatures and higher at high temperatures.
1	Manual Self-refresh reference must be applied.

Bit 16 – APDE Active Power Down Exit Time

This mode is unique to the DDR2-SDRAM and DDR3-SDRAM devices.
This mode manages the active Power-down mode which determines performance versus power saving.
After the initialization sequence, as soon as the APDE field is modified, the Extended Mode register (located in the memory of the external device) is accessed automatically and APDE bits are updated. Depending on the UPD_MR bit, update is done before entering Self-refresh mode or during a refresh command and a pending read or write access

Value	Name	Description
0	DDR2_FAST_EXIT	Fast exit from power-down. DDR2-SDRAM and DDR3-SDRAM devices only.
1	DDR2_SLOW_EXIT	Slow exit from power-down. DDR2-SDRAM and DDR3-SDRAM devices only.

Bit 15 – SRT High Temperature Self-Refresh Rate

This mode is unique to DDR2-SDRAM and DDR3-SDRAM devices supporting the extended temperature range.

Value	Description
1	2x refresh rate. Provides a faster rate on industrial and automotive devices if temperature exceeds 85°C.
0	1x refresh rate. Industrial and automotive devices with temperatures that do not exceed 85°C.

Bit 14 – SELFAUTO Self-Refresh Exit Auto-Refresh

Value	Description
1	Upon exiting Self-refresh mode, auto-refresh command is immediately performed after t_{XSNR}.
0	Upon exiting Self-refresh mode, active command is immediately performed after t_{XSNR}. The auto-refresh command is issued every 15.6 µs or less.

Bits 13:12 – TIMEOUT[1:0] Time Between Last Transfer and Low-Power Mode

Defines when Low-power mode is activated.

Value	Name	Description
0	NONE	SDRAM Low-power mode is activated immediately after the end of the last transfer.
1	DELAY_64_CLK	SDRAM Low-power mode is activated 64 clock cycles after the end of the last transfer.
2	DELAY_128_CLK	SDRAM Low-power mode is activated 128 clock cycles after the end of the last transfer.
3	–	Reserved

Bit 2 – CLK_FR Clock Frozen Command Bit

Sets the clock low during Power-down mode. Some DDR-SDRAM devices do not support freezing the clock during Power-down mode. Refer to the relevant DDR-SDRAM device data sheet for details.

Value	Name	Description
0	DISABLED	Clock(s) is/are not frozen.
1	ENABLED	Clock(s) is/are frozen.

Bits 1:0 – LPCB[1:0] Low-power Command Bit

Value	Name	Description
0	NOLOWPOWER	Low-power feature is inhibited. No Power-down, Self-refresh and Deep power modes are issued to the DDR-SDRAM device.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
1	SELFREFRESH	The MPDDRC issues a self-refresh command to the DDR-SDRAM device, the clock(s) is/are deactivated and the CKE signal is set low. The DDR-SDRAM device leaves the Self-refresh mode when accessed and reenters it after the access.
2	POWERDOWN	The MPDDRC issues a Power-down command to the DDR-SDRAM device after each access, the CKE signal is set low. The DDR-SDRAM device leaves the Power-down mode when accessed and reenters it after the access.

© 2026 Microchip Technology Inc. and its subsidiaries

23.7.8. MPDDRC Memory Device Register

Name: MPDDRC_MD
Offset: 0x20
Reset: 0x00000013
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the MPDDRC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

23.7.9. MPDDRC DDR3 Calibration Register

Name: MPDDRC_DDR3_CAL
Offset: 0x2C
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the MPDDRC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	COUNT_CAL[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	COUNT_CAL[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 15:0 – COUNT_CAL[15:0] DDR3 Calibration Timer Count

This 16-bit field is loaded into a timer which generates the calibration pulse. Each time the calibration pulse is generated, a ZQCS calibration sequence is initiated. The ZQCS Calibration command is used to calibrate DRAM Ron values over PVT. One ZQCS command can effectively correct at least 1.5% of output impedance errors within T_{zqcs}.

One method for calculating the interval between ZQCS commands gives the temperature ($T_{driftrate}$) and voltage ($V_{driftrate}$) drift rates to which the SDRAM is subject in the application. The interval could be defined by the following formula:

- $ZQCorrection/((T_{Sens} \times T_{driftrate}) + (V_{Sens} \times V_{driftrate}))$

where T_{Sens} = max(dRONdTM) and V_{Sens} = max(dRONdVM) define the SDRAM temperature and voltage sensitivities.

For example, if T_{Sens} = 0.75%/C, V_{Sens} = 0.2%/mV, $T_{driftrate}$ = 1C/sec and $V_{driftrate}$ = 15 mV/s, then the interval between ZQCS commands is calculated as:

- $1.5/((0.75 \times 1) + (0.2 \times 15)) = 0.4s$

In this example, the devices require a calibration every 0.4s. The value to be loaded depends on the average time between the REFRESH commands, t_{REF}. For example, for a device with the time between refresh of 7.8 µs, the value of the COUNT_CAL field is programmed as follows: $(0.4/7.8 \times 10^{-6}) = 0xC852$.

T_{Sens} and V_{Sens} are provided by the manufacturer (Output Driver Sensitivity definition). $T_{driftrate}$ and $V_{driftrate}$ are defined by the end user.

© 2026 Microchip Technology Inc. and its subsidiaries

23.7.10. MPDDRC DDR3 Timing Calibration Register

Name: MPDDRC_DDR3_TIM_CAL
Offset: 0x30
Reset: 0x00000006
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset

Reset	0	0	0	0	0	1	1	0

Bits 7:0 – ZQCS[7:0] ZQ Calibration Short
Defines the delay between the ZQ Calibration command and any valid command in number of DDRCK clock cycles.
The number of cycles is between 0 and 255. This field applies to DDR3 devices.

© 2026 Microchip Technology Inc. and its subsidiaries

23.7.11. MPDDRC I/O Calibration Register

Name: MPDDRC_IO_CALIBR
Offset: 0x34
Reset: 0x00870000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	CALCODEN[3:0]				CALCODEP[3:0]			
Access	R	R	R	R	R	R	R	R
Reset	1	0	0	0	0	1	1	1

Bit	15	14	13	12	11	10	9	8
		TZQIO[8:2]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	TZQIO[1:0]		EN_CALIB	CK_F_RANGE[4:0]				
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 23:20 – CALCODEN[3:0] Number of N-type Transistors
Gives the number of N-type transistors to perform the calibration.

Bits 19:16 – CALCODEP[3:0] Number of P-type Transistors
Gives the number of P-type transistors to perform the calibration.

Bits 14:6 – TZQIO[8:0] IO Calibration
Defines the delay between the start up of the amplifier and the beginning of the calibration, in number of DDRCK clock cycles. The value of this field must be set to 1.5 µs. The number of cycles is between 0 and 512.
The TZQIO configuration code must be set correctly depending on the clock frequency using the following formula:

- $TZQIO = (DDRCK \times (1.5 \times 10^{-6})) + 1$

where the DDRCK frequency is in Hz.
For example, for a frequency of 266 MHz, the value of the TZQIO field is configured $(266 \times 10^{6}) \times (1.5 \times 10^{-6}) + 1 = 400$.

Bit 5 – EN_CALIB Enable Calibration
Enables calibration for the DDR2 devices. When the calibration is enabled, it is recommended to define the COUNT_CAL field (see "COUNT_CAL: LPDDR2 LPDDR3 and DDR3 Calibration Timer Count").
This 16-bit field is loaded into a timer which generates the calibration pulse. Each time the calibration pulse is generated, a calibration sequence is initiated.

Value	Name	Description
0	DISABLE_CALIBRATION	Calibration is disabled.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
1	ENABLE_CALIBRATION	Calibration is enabled.

Bits 4:0 – CK_F_RANGE[4:0] DDRCK Maximum Clock Frequency Range
This field is written only once at the initialization sequence and is always written to 1F whatever the frequency configured on DDRCK.

© 2026 Microchip Technology Inc. and its subsidiaries

23.7.12. MPDDRC OCMS Register

Name: MPDDRC_OCMS
Offset: 0x38
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the MPDDRC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Bit	7	6	5	4	3	2	1	0
				TAMPCLR				SCR_EN
Access				R/W				R/W
Reset				0				0

Bit 4 – TAMPCLR Tamper Clear Enable

Value	Description
0	A tamper detection event has no effect on MPDDRC scrambling keys.
1	A tamper detection event immediately clears MPDDRC scrambling keys.

Bit 0 – SCR_EN Scrambling Enable

Value	Description
0	Disables “Off-chip” scrambling for SDRAM access.
1	Enables “Off-chip” scrambling for SDRAM access.

© 2026 Microchip Technology Inc. and its subsidiaries

23.7.13. MPDDRC OCMS KEY1 Register

Name: MPDDRC_OCMS_KEY1
Offset: 0x3C
Reset: –
Property: Write-only

This register can only be written if the WPEN bit is cleared in the MPDDRC Write Protection Mode Register.

This register can only be written once.

Reset					0	0	0	0

Bits 24, 25, 26, 27, 28, 29, 30 – BDW_BURST_Px Bandwidth Arbitration Mode on Port X

Value	Description
0	The arbitration is done when the bandwidth limit defined in MPDDRC_BDW_PORT_0123/456.BDW_Px is reached. If the bandwidth limit is reached during a burst access, the burst is completed.
1	The arbitration is done when the bandwidth limit defined in MPDDRC_BDW_PORT_0123/456.BDW_Px is reached. If the bandwidth limit is reached during a burst access, the burst is broken.

Bits 16, 17, 18, 19, 20, 21, 22 – MA_PR_Px Host or Software Provide Information

Value	Description
0	Number of requests or words is provided by the host, if the host supports this feature.
1	Number of requests or words is provided by software, see "NRQ_NWD_BDW_Px: Number of Requests, Number of Words or Bandwidth Allocation from Port 0-1-2-3".

Bits 8, 9, 10, 11, 12, 13, 14 – RQ_WD_Px Request or Word from Port X

Value	Description
0	Number of requests is selected.
1	Number of words is selected.

Bit 3 – BDW_MAX_CUR Bandwidth Max or Current

Displays the maximum bandwidth or the current bandwidth for each port.
The maximum bandwidth is computed when at least two ports of MPDDRC are used.
This information is provided in MPDDRC Current/Maximum Bandwidth Port 0-1-2-3 Register and MPDDRC Current/Maximum Bandwidth Port 4-5-6-7 Register.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	Current bandwidth is displayed.
1	Maximum bandwidth is displayed.

Bit 2 – KEEP_LAYER Layer (Port) Kept by Host

Selects the type of arbitration: round-robin, number of requests per port or bandwidth per port.

Value	Description
0	No impact on arbitration scheme
1	Some hosts, such as LCD or DMA, drive a signal named HNBREQ on the system bus to indicate the number of transfers to be performed. The host with the highest LQOS value and a HNBREQ value different from 0 continues to be granted, even during a last data phase with IDLE cycles. This function is effective if the type of arbitration is LQOS.

Bits 1:0 – ARB[1:0] Type of Arbitration

Selects the type of arbitration: round-robin, number of requests per port or bandwidth per port.

Value	Name	Description
0	ROUND	Round-robin policy
1	NB_REQUEST	Request policy
2	BANDWIDTH	Bandwidth policy
3	LQOS	Quality of Service policy

Bits 0:3, 4:7, 8:11, 12:15, 16:19, 20:23, 24:27 – TIMEOUT_Px Timeout for Ports 0, 1, 2, 3, 4, 5, 6
Some hosts insert an idle state between two accesses. This field defines the delay between two accesses on the same port in number of DDRCK clock cycles before arbitration and handing the access over to another port.
This field is not used with round-robin and bandwidth arbitrations.
The number of cycles is between 1 and 15.

23.7.17. MPDDRC Request Port 0-1-2-3 Register

Name: MPDDRC_REQ_PORT_0123
Offset: 0x4C
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	NRQ_NWD_BDW_P3[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	NRQ_NWD_BDW_P2[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	NRQ_NWD_BDW_P1[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	NRQ_NWD_BDW_P0[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 0:7, 8:15, 16:23, 24:31 – NRQ_NWD_BDW_Px Number of Requests, Number of Words or Bandwidth Allocation from Port 0-1-2-3

The number of requests corresponds to the number of start transfers. For example, setting this field to 2 performs two burst accesses regardless of the burst type (INCR4, INCR8, etc.). The number of words corresponds exactly to the number of accesses; setting this field to 2 performs two accesses. In this example, burst accesses will be broken.
These values depend on scheme arbitration (see MPDDRC Configuration Arbiter Register).
In case of round-robin arbitration, this field is not used. In case of “bandwidth arbitration”, this field corresponds to percentage allocated for each port. In case of “request” arbitration, this field corresponds to number of start transfers or to number of accesses allocated for each port.

							SHIFT_SAMPLING[1:0]	
Access							R/W	R/W
Reset							0	0

Bits 1:0 – SHIFT_SAMPLING[1:0] Shift Sampling Point of Data
Shifts the sampling point of data coming from the memory device. The higher the memory device clock frequency, the higher the SHIFT_SAMPLING value. Refer to the section "Electrical Characteristics".

Value	Name	Description
0	NO_SHIFT	Initial sampling point.
1	SHIFT_ONE_CYCLE	Sampling point is shifted by one cycle.
2	SHIFT_TWO_CYCLES	Sampling point is shifted by two cycles.
3	SHIFT_THREE_CYCLES	Sampling point is shifted by three cycles, unique for DDR2 and DDR3.

Bit	7	6	5	4	3	2	1	0
				RUN			SOFT_RESET	EN_MONI
Access				R/W			R/W	R/W
Reset				0			0	0

Bits 13:11 – INFO[2:0] Information Type
Reports information such as latency and the number of transfers monitored on port x [x = 0..6].

Value	Name	Description
0	MAX_WAIT	Information concerning the transfer with the longest waiting time
1	NB_TRANSFERS	Number of transfers on the port
2	TOTAL_LATENCY	Total latency on the port
3	–	Reserved
4	MAX_WAIT_QOS01	Information concerning the transfer with the longest waiting time, depending on QOS values (0 and 1)
5	MAX_WAIT_QOS23	Information concerning the transfer with the longest waiting time, depending on QOS values (2 and 3)
6	TOTAL_CYCLE_COUNT	Indicates the total number of cycles from beginning to end of monitoring.

Bit 10 – REFR_CALIB Refresh Calibration

Value	Description
0	Monitoring does not depend on Auto-refresh mode, Self-refresh mode, Power-down mode, DLL nor calibration impact.
1	Monitoring depends on Auto-refresh mode, Self-refresh mode, Power-down mode, DLL and calibration impact.

Bits 9:8 – READ_WRITE[1:0] Read/Write Access
Used to monitor different types of access.

Value	Name	Description
0	TRIG_RD_WR	Read and Write accesses are triggered.
1	TRIG_WR	Only Write accesses are triggered.
2	TRIG_RD	Only Read accesses are triggered.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
3	–	Reserved

Bit 4 – RUN Control Monitor

Value	Description
0	Monitoring is halted. All counters are stopped.
1	Monitoring is launched.

Bit 1 – SOFT_RESET Soft Reset

Value	Description
0	Soft reset is not performed.
1	Soft reset is performed.

Bit 0 – EN_MONI Enable Monitor

Value	Description
0	Monitor is disabled.
1	Monitor is enabled.

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:16 – ADDR_HIGH_PORTx[15:0] Address High on Port x
Address high which defines the interval to be monitored on port x. This address must be programmed according to the memory mapping of the product.

Bits 15:0 – ADDR_LOW_PORTx[15:0] Address Low on Port x
Address low which defines the interval to be monitored on port x. This address must be programmed according to the memory mapping of the product.

	MAX_PORTx_WAITING[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 26:25 – LQOS[1:0] Value of Quality Of Service on Port x
Can be read if the INFO field in the MPDDRC Monitor Configuration register is set to 0.
This field reports the Quality of Service value for the maximum waiting time.

Value	Name	Description
0	BACKGROUND	Background transfers
1	BANDWIDTH	Bandwidth sensitive
2	SENSITIVE_LAT	Latency sensitive
3	CRITICAL_LAT	Latency critical

Bit 24 – READ_WRITE Read or Write Access on Port x
Can be read if the INFO field in the MPDDRC Monitor Configuration register is set to 0.
Reports the transfer direction for the maximum waiting time.

Value	Description
0	Read transfer
1	Write transfer

Bits 22:20 – SIZE[2:0] Transfer Size on Port x
Can be read if the INFO field in the MPDDRC Monitor Configuration register is set to 0.
Reports the size of the transfer for the maximum waiting time.

Value	Name	Description
0	8BITS	Byte transfer
1	16BITS	Halfword transfer
2	32BITS	Word transfer
3	64BITS	Dword transfer
4–7	–	Reserved

© 2026 Microchip Technology Inc. and its subsidiaries

Bits 18:16 – BURST[2:0] Type of Burst on Port x

Can be read if the INFO field in the MPDDRC Monitor Configuration register is set to 0.
Reports the type of burst for the maximum waiting time.

Value	Name	Description
0	SINGLE	Single transfer
1	INCR	Incrementing burst of unspecified length
2	WRAP4	4-beat wrapping burst
3	INCR4	4-beat incrementing burst
4	WRAP8	8-beat wrapping burst
5	INCR8	8-beat incrementing burst
6	WRAP16	16-beat wrapping burst
7	INCR16	16-beat incrementing burst

Bits 15:0 – MAX_PORTx_WAITING[15:0] Address High on Port x

Can be read if the INFO field in the MPDDRC Monitor Configuration register is set to 0.
Reports the maximum waiting time and the associated type of transfer (burst, size, read or write).

© 2026 Microchip Technology Inc. and its subsidiaries

23.7.25. MPDDRC Monitor Information Port x Register (NB_TRANSFERS)

Name: MPDDRC_MINFOx (NB_TRANSFERS)

Bits 31:16 – Px_TOTAL_LATENCY_QOS1[15:0] Total Latency on Port x when value of qos is 1
Can be read if the INFO field is set to 4.
Reports the total latency within an interval (ADDR_HIGH_PORT and ADDR_LOW_PORT) when the port is used with qos = 1.

Bits 15:0 – Px_TOTAL_LATENCY_QOS0[15:0] Total Latency on Port x when value of qos is 0
Can be read if the INFO field is set to 4.
Reports the total latency within an interval (ADDR_HIGH_PORT and ADDR_LOW_PORT) when the port is used with qos = 0.

© 2026 Microchip Technology Inc. and its subsidiaries

23.7.28. MPDDRC Monitor Information Port x Register (TOTAL_LATENCY_QOS23)

Name: MPDDRC_MINFOx (TOTAL_LATENCY_QOS23)

	TOTAL_CYCLE_COUNT[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – TOTAL_CYCLE_COUNT[31:0] Total Cycle Count
Can be read if the INFO field is set to 6.
This field reports the total number of cycles from monitor launch to monitor halt.

© 2026 Microchip Technology Inc. and its subsidiaries

23.7.30. MPDDRC Interrupt Enable Register

Name: MPDDRC_IER
Offset: 0xC0
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the MPDDRC Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

23.7.31. MPDDRC Interrupt Disable Register

Name: MPDDRC_IDR
Offset: 0xC4
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the MPDDRC Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x444452	PASSWD	Writing any other value in this field aborts the write operation of the WPEN and WPITEN bits. Always reads as 0.

Bit 4 – FIRSTE First Error Report Enable

Value	Description
0	The last write protection violation source is reported in MPDDRC_WPSR.WPVSRC and the last software control error type is reported in MPDDRC_WPSR.SWETYP. The MPDDRC_ISR.SEC flag is set at the first error occurrence within a series.
1	Only the first write protection violation source is reported in MPDDRC_WPSR.WPVSRC and only the first software control error type is reported in MPDDRC_WPSR.SWETYP. The MPDDRC_ISR.SEC flag is set at the first error occurrence within a series.

Bit 1 – WPITEN Write Protection Interruption Enable

Value	Description
0	Disables the write protection on interrupt registers if WPKEY corresponds to 0x444452 (“DDR” in ASCII).
1	Enables the write protection on interrupt registers if WPKEY corresponds to 0x444452 (“DDR” in ASCII).

Bit 0 – WPEN Write Protection Enable

Value	Description
0	Disables the write protection if WPKEY corresponds to 0x444452 (“DDR” in ASCII).
1	Enables the write protection if WPKEY corresponds to 0x444452 (“DDR” in ASCII).

23.7.36. MPDDRC Write Protection Status Register

Name: MPDDRC_WPSR
Offset: 0xE8
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	ECLASS						SWETYP[1:0]	
Access	R						R	R
Reset	0						0	0

Bit	23	22	21	20	19	18	17	16
	WPVSRC[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	WPVSRC[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
					SWE	SEQE	CGD	WPVS
Access					R	R	R	R
Reset					0	0	0	0

Bit 31 – ECLASS Software Error Class (cleared on read)
0 (WARNING): An abnormal access that does not affect system functionality is performed.
1 (ERROR): An access is performed into some registers after memory device initialization sequence.

Bits 25:24 – SWETYP[1:0] Software Error Type (cleared on read)

Value	Name	Description
0	READ_WO	A write-only register has been read (warning).
1	WRITE_RO	MPDDRC is enabled and a write access has been performed on a read-only register (warning).
2	UNDEF_RW	Access to an undefined address (warning).
3	W_AFTER_INIT	Abnormal use of MPDDRC user interface when memory device is already configured and initialized, i.e., if MPDDRC_RTR.COUNT > 0 (error).

Bits 23:8 – WPVSRC[15:0] Write Protection Violation Source
When WPVS = 1, WPVSRC indicates the register address offset at which a write access has been attempted.

Bit 3 – SWE Software Control Error (cleared on read)

Value	Description
0	No software error has occurred since the last read of MPDDRC_WPSR.
1	A software error has occurred since the last read of MPDDRC_WPSR. The field SWE details the type of software error. The associated incorrect software access is reported in the field WPVSRC (if WPVS=0).

Bit 2 – SEQE Internal Sequencer Error or Non-Correctable Error on Configuration Registers (cleared on read)

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	In the registers listed below, no peripheral internal sequencer error has occurred or no single error has occurred since the last read of MPDDRC_WPSR: • Mode register (MPDDRC_MR) • Memory Device register (MPDDRC_MD • Refresh Timer register (MPDDRC_RTR) • Timing Parameter 0/1/2 registers (MPDDRC_TPR0/1/2) • Low-Power register (MPDDRC_LPR) • Configuration register (MPDDRC_CR) • OCMS KEY1 register (MPDDRC_OCMS_KEY1) • OCMS KEY2 register (MPDDRC_OCMS_KEY2)
1	A peripheral internal sequencer error has occurred since the last read of MPDDRC_WPSR. In the registers listed below, this flag can only be set under abnormal operating conditions or if a non-correctable error has occurred since the last read of MPDDRC_WPSR: • Mode register (MPDDRC_MR) • Memory Device register (MPDDRC_MD • Refresh Timer register (MPDDRC_RTR) • Timing Parameter 0/1/2 registers (MPDDRC_TPR0/1/2) • Low-Power register (MPDDRC_LPR) • Configuration register (MPDDRC_CR) • OCMS KEY1 register (MPDDRC_OCMS_KEY1) • OCMS KEY2 register (MPDDRC_OCMS_KEY2) **Note:** The error is not corrected and the software must reconfigure all registers.

Bit 1 – CGD Clock Glitch Detected (cleared on read)

Value	Description
0	The clock monitoring circuitry has not been corrupted since the last read of MPDDRC_WPSR. Under normal operating conditions, this bit is always cleared.
1	The clock monitoring circuitry has been corrupted since the last read of MPDDRC_WPSR. This flag can only be set in case of an abnormal clock signal waveform (glitch).

Bit 0 – WPVS Write Protection Enable

Value	Description
0	No write protection violation occurred since the last read of this register (MPDDRC_WPSR).
1	A write protection violation occurred since the last read of this register (MPDDRC_WPSR). If this violation is an unauthorized attempt to write a control register, the associated violation is reported into the WPVSRC field.

© 2026 Microchip Technology Inc. and its subsidiaries

24. OTP Memory Controller (OTPC)

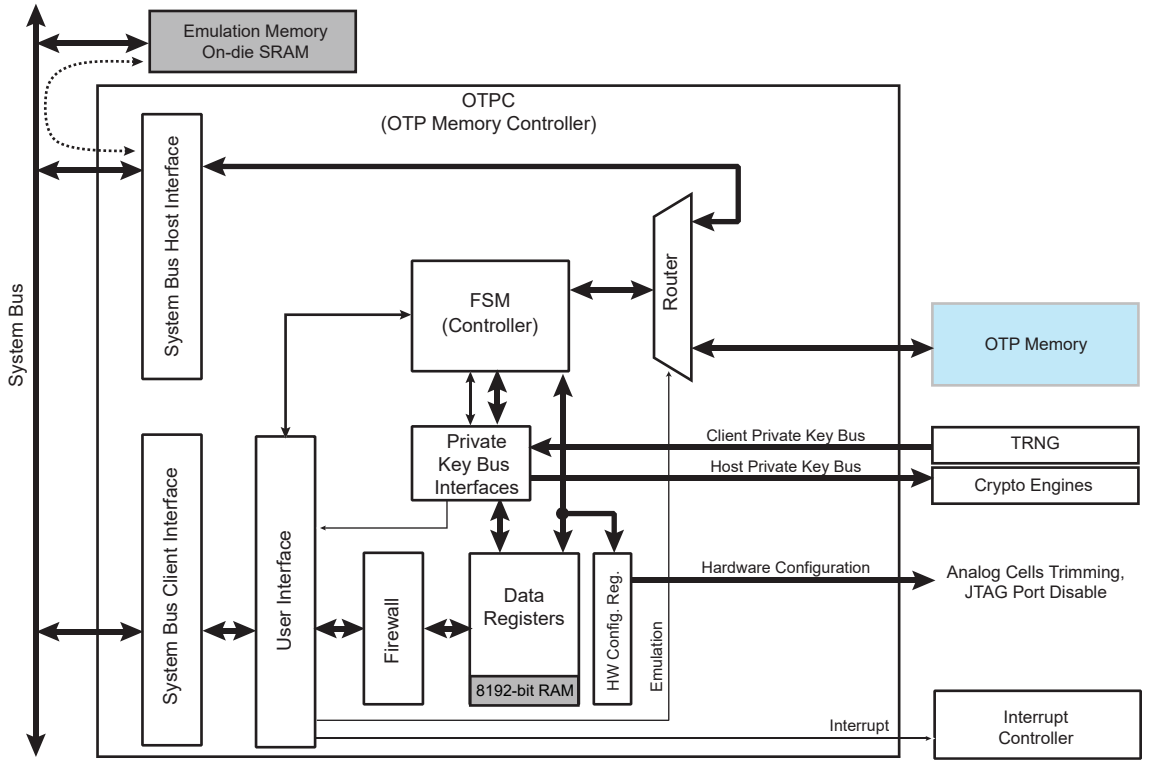
24.1. Description

The One-Time Programmable (OTP) Memory Controller (OTPC) is the secure interface between the system and the OTP memory.

The default value of a memory bit is logic ‘0’ (not programmed). A programmed memory bit is logic ‘1’.

An OTP matrix is a type of non-volatile memory. Each bit in the matrix can be programmed only once. The bits are used to store data such as:

- calibration bits for analog cells (for example, RC oscillators, etc.),
- hardware configuration settings (for example, JTAG disable, etc.),
- chip identifiers,
- key data invisible by software,
- user data.



24.2. Embedded Characteristics

- Programs and Reads the Memory by Software
- Emulation Mode
- Automatic Check of Programmed Bits on Start-up for Safe Operation
- OTP Live Repair
- User Area Organized by Packet for Flexibility on Size and Security:
  - Individual packet locking possibility (with checksum check)
  - Individual packet read access through only Private Key bus or System bus
  - Individual packet hiding (for packet with System bus access only)
  - Individual packet size of 32 bits to 8192 bits in 32-bit steps
  - Individual packet invalidation
- Firewall: Software/Hardware Protection Against Unexpected Read/Write

© 2026 Microchip Technology Inc. and its subsidiaries

24.3. Block Diagram

Figure 24.1. OTPC Block Diagram

24.4. Product Dependencies

24.4.1. Power Management

The OTPC is clocked through the Power Management Controller (PMC). The user must power on the main RC oscillator and enable the peripheral clock of the OTPC prior to reading or writing the OTP memory.

24.4.2. Interrupt Sources

The OTPC interface has an interrupt line connected to the Interrupt Controller.

Handling the OTPC interrupt requires programming the Interrupt Controller before configuring the OTPC.

24.5. Functional Description

24.5.1. Bus Interfaces

The OTPC features four bus interfaces to access the OTP memory:

- Host system bus
- Client system bus
- Host key bus (private key bus)
- Client key bus (private key bus)

The host system bus is used in Emulation mode to write and read data to/from the Emulation memory instead of the OTP memory. The host system bus can only access the emulation memory.

The client system bus is available to access to the user interface.

© 2026 Microchip Technology Inc. and its subsidiaries

The host key bus is available to read keys stored in the User area of the OTP memory and transfer them to the client crypto-engines connected to this bus (e.g. AES). No data accessible to the host key bus are accessible to the System bus.

The client key bus is available to write some data to the User area of the OTP memory. No data coming from the client key bus are accessible to the system bus.

24.5.2. OTP Memory Partitioning

The OTP memory is partitioned into different areas:

- Reserved area
- 10-Kbyte User area

The initial value of the OTP memory is '0' but the memory may contain some "defective" bits already set to the value '1'.

The memory is organized into 32-bit words.

24.5.3. User Area

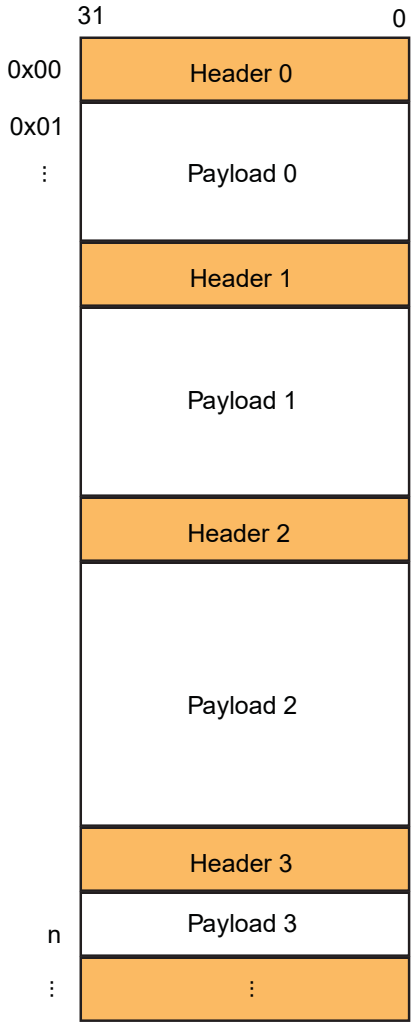
24.5.3.1. Area Configuration and Control

The User area is controlled and configured through the OTPC Control (OTPC_CR), OTPC Mode (OTPC_MR) and OTPC Data (OTPC_DR) registers.

24.5.3.2. Area Mapping

The entire User area space is mapped into 32-bit words. Each 32-bit word is part of one packet.

Each packet contains a 32-bit header and 32-bit words of payload (data). The number of payload words is defined in the header.



This mapping system allows three important functions for an OTP memory:

- Gives a flexible size for any type of data
- Improves security by identifying and masking key areas to the System bus,
- Provides an easy way to invalidate a packet and create a replacement packet (key, data) while free space is available in OTP.

The packet organization into the User area is shown in the figure below.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 24.2. User Area Memory Mapping

The number of packets depends on the size of the User area and the size of each packet.

24.5.3.3.Packet Definition

Each packet contains:

- One 32-bit header field
- One payload field containing at least 32 bits of data and up to 256 x 32 bits of data (8192 bits)

The payload field has no effect on the hardware except for “special” packets.

24.5.3.3.1.Header Field

The following table provides the definition of the header content.

31	30	29	28	27	26	25	24
CHECKSUM							
23	22	21	20	19	18	17	16
CHECKSUM							
15	14	13	12	11	10	9	8
SIZE							
7	6	5	4	3	2	1	0
ONE	–	INVLD		LOCK	PACKET		

© 2026 Microchip Technology Inc. and its subsidiaries

- PACKET: Indicates the packet type. Six types are available:
  - REGULAR packet (value 1) accessible through the User Interface
  - KEY packet (value 2) accessible only through the Private Key buses
  - BOOT_CONFIGURATION “special” packet (value 3)
  - SECURE_BOOT_CONFIGURATION “special” packet (value 4)
  - HARDWARE_CONFIGURATION “special” packet (value 5)
  - CUSTOM “special” packet (value 6)
- LOCK: Written by the controller when the checksum is generated.
- INVLD: Written when an invalidation process is requested.
- ONE: Must be written to ‘1’.
- SIZE: Indicates the size in 32-bit words of the payload field. SIZE = 0 means payload is 32-bit size, SIZE = 255 means payload is 8192-bit size.
  The entire packet size (in bits) in OTP memory is 32 (header) + (32 * (SIZE + 1)).
- CHECKSUM: Represents the checksum of the packet excluding the CHECKSUM field of the header. The real value of the CHECKSUM field is not readable; it is generated by the OTPC.
  - When CHECKSUM is read as 0, the checksum has not been generated. It is possible to modify the packet content.
  - When CHECKSUM is read as 0x33CC, the checksum has not been generated but some bits are already at 1. Locking the packet may fail.
  - When CHECKSUM is read as 0xA5A5, the checksum has been generated and the last check was successful. It is impossible to modify the packet content.
  - When CHECKSUM is read as 0xCC33, the header of the packet is corrupted.
  - When CHECKSUM is read as 0xFFFF, the entire packet is no longer valid. It is possible to modify the packet content and it is up to the software to program the payload to a different value if needed.
  - For all other values of CHECKSUM, the checksum has been generated and the last check failed to match the checksum written in the OTP memory. It is impossible to modify the packet content.

24.5.3.3.2. “Special” Packets

The payload of “special” packets is interpreted by the OTPC and some actions can be triggered while the “special” packets are read. The address of the “special” packets inside the area does not matter.

If the checksum has been generated and does not match during the last read, the payload is not interpreted by the OTPC.

The table below provides the list of “special” packets.

Table 24.1. “Special” Packets

Name	SIZE	PACKET	Description
Boot Configuration	(see Note 1)	3	Boot configuration
Secure Boot Configuration	(see Note 1)	4	Secure Boot configuration
User Hardware Configuration	1	5	Hardware configuration
Custom	N/A	6	For user custom purposes. The size of this packet is user application dependent.

Note:

1. For details, refer to the section “Boot Strategies”.

© 2026 Microchip Technology Inc. and its subsidiaries

The address of the Boot Configuration and Secure Boot Configuration special packets can be retrieved in the OTPC Boot Addresses (OTPC_BAR) register.

The address of the Custom special packets can be retrieved in the OTPC Custom Address (OTPC_CAR) register.

For each “special” packets, if there is more than one valid packet (of the same type), only the last packet will be considered (previous packets will be ignored). It is recommended to invalidate prior “special” packets to keep only one valid packet for each “special” packet type.

24.5.3.4.Init

After each reset, the OTPC parses the User area to check its content. The header of each packet will be read, depending on the header value some actions can be triggered:

- If the header is corrupted, the init sequence is interrupted and the OTPC_ISR.COERR bit is set.
- If the INVLD field of the header is 3, the OTPC ignores the packet and jumps to the next header.
- If the LOCK bit of the header is set, the payload is read and the checksum computed during the read is compared to the checksum saved in the header. If the checksums do not match, the OTPC_ISR.CKERR bit will be set.
- If the PACKET field of the header is BOOT_CONFIGURATION, the address of the packet will be stored in the OTPC_BAR.BCADDR field. Any previous value stored in the OTPC_BAR.BCADDR field is lost.
- If the PACKET field of the header is SECURE_BOOT_CONFIGURATION, the address of the packet will be stored in the OTPC_BAR.SBCADDR field. Any previous value stored in the OTPC_BAR.SBCADDR field is lost.
- If the PACKET field of the header is HARDWARE_CONFIGURATION, the payload is read and stored in the OTPC User Hardware Configuration (OTPC_UHCxR) registers (unless the checksums do not match if the packet is locked, in that case the reset value of the OTPC_UHCxR registers is stored). Any previous value stored in the OTPC_UHCxR registers is lost.
- If the PACKET field of the header is CUSTOM, the address of the packet will be stored in the OTPC_CAR.CADDR field. Any previous value stored in the OTPC_CAR.CADDR field is lost.

At the end of the init sequence, the value of the last HARDWARE_CONFIGURATION “special“ packet found is applied to the hardware.

24.5.3.5.Read Access

The User area can be read through the User interface at any time after a reset. Each packet is available through the OTPC_DR register. To trigger a packet read, follow the steps below:

1. The address of the header (or any address of the payload) must be written in OTPC_MR.ADDR.
2. OTPC_CR.READ must be set to ‘1’ (the OTPC_CR.KEY field value does not matter).
3. Wait for OTPC_ISR.EOR to be set to ‘1’ or for OTPC_SR.READ to be set to ‘0’, indicating that the whole packet has been transferred into temporary registers.
4. Read the header of the packet in the OTPC_HR register. To read each payload word, the address of the payload word must be written in OTPC_AR.DADDR. The payload word is then available in OTPC_DR.
   If OTPC_AR.INCRT is set to AFTER_READ, any read in the OTPC_DR increments the DADDR field.
   If INCRT is set to AFTER_WRITE, any write in the OTPC_DR increments the DADDR field.

The payload of a packet with PACKET set to KEY is read as ‘0’. The payload of a packet hidden since the last reset is read as ‘0’.

24.5.3.5.1.Transfer a Packet through the Host Key Bus

To transfer a packet from the OTP memory through the host key bus, follow the steps below:

1. The address of the header (or any address of the payload) must be written in OTPC_MR.ADDR. Only the packets with the packet type set to KEY are transferable on the host key bus.

© 2026 Microchip Technology Inc. and its subsidiaries

2. The key bus destination must be written in OTPC_MR.KBDST.
3. Write 0x7167in the OTPC_CR.KEY field and '1' to OTPC_CR.KBSTART.

The end of the transfer is indicated by OTPC_ISR.EOKT='1' and/or OTPC_SR.MKBB='0'.

If the type of the packet is not KEY, OTPC_ISR.KBERR is set.

To cancel a packet transfer, OTPC_CR.KEY must be set to 0x7167 and KBSTOP must be set.

24.5.3.5.2.Hiding a Packet

For security reasons, it is possible to hide a packet after having read it through the User Interface. Once hidden, any read to the payload of the packet returns '0'.

To unhide a packet, a reset is necessary.

Hiding a packet does not make it available through the Key Buses.

To hide a packet, follow the steps below:

1. Write the address value of the header of the packet to hide in OTPC_MR.ADDR.
2. Write 0x7167 in OTPC_CR.KEY and '1' to HIDE.

24.5.3.6.Write (Program) Considerations

Each word of the User area can be written only once. It is possible to write a packet payload partially and/or update a packet payload already written.

The packet to write (either the header or the payload) may contain some bits already at '1'. In this case, a dummy packet can be used to write the packet in a different location. The OTPC may also be able to fix the '1' already written if this bit also matches the packet to write. Thus before writing any new packet, it is necessary to proceed to a read at the last address.

24.5.3.6.1.'1' in the Header

After the read, the header may contain one or more '1's. If the '1's match the '1's to write in the header, the packet can be written.

If the '1's do not all match the '1's to write in the header, the packet cannot be written. It is mandatory to create (and then invalidate if necessary) a packet with a compatible header.

24.5.3.6.2.'1' in the Payload

If the payload is written and then updated later, the '1's already written must match the '1's to write.

If the payload is written only once (no update later), the '1's already written must all match either the '1' or the '0' to write (it cannot be a mix of '1's and '0's to write).

24.5.3.7.Write (Program) Access

The User area can be programmed at any time after a reset until OTPC_MR.WRDIS has been set.

24.5.3.7.1.Writing a New Packet from the User Interface

To write a new packet from the User Interface, follow the steps below:

1. Write OTPC_MR.NPCKT to '0' if it is set at '1'.
2. Write OTPC_MR.ADDR to its maximum value.
3. Write a '1' to OTPC_CR.READ and wait for the read completion (OTPC_ISR.EOR='1' when the read is completed).
4. Check there is no bit already set to '1' in the OTPC_HR and OTPC_DR. The check for the data registers can be replaced by reading OTPC_SR.ONEF (if ONEF is set, at least one bit of the data registers is set to '1').
   If the header or the payload of the packet already contains a 1, the new packet may need to be adapted.
5. Write OTPC_MR.ADDR to '0' and set NPCKT.

© 2026 Microchip Technology Inc. and its subsidiaries

Depending on the contents of the temporary registers, an automatic flush can be triggered. If an automatic flush is started, OTPC_SR.FLUSH is set and OTPC_ISR.EOF is raised at the completion of the flush. It is mandatory to wait for the end of the flush.

6. Write the header value in OTPC_HR. The value of PACKET must not be the same as KEY.
7. Set DADDR to ‘0’.
8. Write the first data in the OTPC_DR register. To update the 32-bit data later (using the packet update), the OTPC_DR register must be set to 0.
9. Increment the DADDR field and write the next data in the OTPC_DR. Repeat this operation until all the data has been written.
   Skip the increment of DADDR if INCRT is set to AFTER_WRITE.
10. Write USER_KEY in the OTPC_CR.KEY field and ‘1’ to OTPC_CR.PGM.

Before the write operation in the OTP memory, the OTPC checks the consistency of the packet and that the packet does not overlap on any existing packet. In case of error, OTPC_ISR.WERR is set and the write operation is cancelled.

The end of the programming operation is indicated by OTPC_ISR.EOP=’1’ and/or OTPC_SR.PGM=’0’. At the end of the programming, the address of the header is available in OTPC_MR.ADDR and the OTPC_MR.NPCKT must be cleared.

The payload can be read back before programming. After read back, it is possible to update PACKET value to KEY before programming.

If the new written packet is the User Hardware Configuration special packet, its payload is ignored until the next reset or the next refresh. The OTPC_UHCxR registers will be updated after the reset or the refresh following programming.

24.5.3.7.2.Updating an Existing Packet from the User Interface

To update an existing packet from the User Interface, follow the steps below:

1. Write the address of the header of the packet to update in OTPC_MR.ADDR.
2. Start a read by setting OTPC_CR.READ and wait for the read completion indicated by OTPC_ISR.EOR.
3. Update the data using the OTPC_AR and OTPC_DR registers. Only the 32-bit data set to 0 can be updated, the non-zero 32-bit data must be left unchanged
4. Write 0x7167 in the OTPC_CR.KEY field and ‘1’ to OTPC_CR.PGM.

The end of the programming operation is indicated by OTPC_ISR.EOP='1' and/or OTPC_SR.PGM='0'.

If the updated packet is the User Hardware Configuration special packet, its new payload is ignored until the next reset. The OTPC_UHCxR registers will be updated after the reset or the refresh following programming.

24.5.3.7.3.Writing a Packet from the Client Key Bus

To write a packet from the client key bus interface (payload only), follow the steps below:

1. Write OTPC_MR.ADDR to ‘0’ and set NPCKT.
   Depending on the content of the temporary registers, an automatic flush can be triggered. If an automatic flush is started, OTPC_SR.FLUSH is set and OTPC_ISR.EOF is raised at the completion of the flush. It is mandatory to wait for the end of the flush.
2. Write the header value in the OTPC_HR register. The value of PACKET must be KEY.
3. Initiate a data transfer to the OTP memory through the TRNG host key bus.
4. Wait for the data transfer completion.
5. Check that no error happened during the key transfer (OTPC_ISR.KBERR must be cleared).
6. Write 0x7167 in the OTPC_CR.KEY field and ‘1’ to OTPC_CR.PGM.

© 2026 Microchip Technology Inc. and its subsidiaries

7. Before the write operation in the OTP memory, the OTPC checks the consistency of the packet and that the packet does not overlap on any existing packet. In case of error, OTPC_ISR.WERR is set and the write operation is cancelled. The end of the programming operation is indicated by OTPC_ISR.EOP=1 and/or OTPC_SR.PGM=0.

If the PACKET field is changed before programming, the payload is erased (and lost).

24.5.3.7.4.Locking a Packet

To lock a packet, follow the steps below:

1. Write the address value of the header of the packet to lock in OTPC_MR.ADDR.
2. Start a read by setting OTPC_CR.READ and waiting for the read completion indicated by OTPC_ISR.EOR.
3. Write 0x7167 in the OTPC_CR.KEY field and '1' in OTPC_CR.CKSGEN.

The end of the lock operation is indicated by OTPC_ISR.EOL='1' and/or OTPC_SR.LOCK='0'.

Generating the checksum locks the packet and modification is no longer possible.

24.5.3.7.5.Invalidating a Packet

To invalidate a packet, follow the steps below:

1. Write the address value of the header of the packet to invalidate in OTPC_MR.ADDR.
2. Write 0x7167 in the OTPC_CR.KEY field and '1' to OTPC_CR.INVLD.

The end of the invalidation operation is indicated by OTPC_ISR.EOI= '1' and/or OTPC_SR.INVLD='0'.

If the invalidated packet is the User Hardware Configuration special packet, its old payload remains active until the next reset or the next refresh. The OTPC_UHCxR registers will be updated after the reset or the refresh following the invalidation operation.

24.5.3.8.Fixing Corruption

During a programming sequence, packet header corruption may occur. This corruption can be caused by a partial programming of the header. It is mandatory to fix any corruption prior to any usage of the Engineering Area or User Area.

During the start sequence, the OTPC stops parsing the OTP memory at the first header corruption detected. When OTPC_ISR.COERR is set, a corruption has been detected. The corrupted header can be read in OTPC_HR and its location can be read in OTPC_MR.ADDR.

A header is corrupted if at least one of the following statements matches:

- The ONE bit is cleared (it must be set to fix the corruption).
- The INVLD field is 3 and the PACKET field is 0 (PACKET must be set to a non-0 value to fix the corruption).
- The SIZE and PACKET fields are not consistent (for PACKET set to PRODUCT_UID, HARDWARE_CONFIGURATION or SECURITY_CONFIGURATION, the packet must be invalidated to fix the corruption).

To fix a corruption, start a a read procedure at the location of the corrupted header. The OTPC reads the payload according to the size provided in the header and reads one extra word of payload, which should match the next header.

The corrupted header must be fixed by writing any missing '1's or, if not possible, by extending its size if the supposed next header is 0, or by invalidating the packet.

A reset is required after fixing the corruption.

24.5.3.9."Software" Protections

The User area can be protected against read accesses and/or modifications.

© 2026 Microchip Technology Inc. and its subsidiaries

To enable read protection of the User data (OTPC_DR) and header (OTPC_HR) registers, OTPC_MR.RDDIS must be set. Clearing RDDIS allows read access again. When the OTPC_DR and OTPC_HR registers are read-protected, any read returns 0.

To enable write protection of the OTPC_DR registers, the WRDIS bit of OTPC_MR should be set. Clearing the WRDIS bit allows write access again.

To enable write protection of the User area, the write protection of the User data registers must be enabled.

The OTPC_MR can be locked until the next reset by setting the LOCK bit of OTPC_MR. Once locked, the current protection configuration of the OTPC_DR and OTPC_HR registers applies, it is then also impossible to update, program, invalidate, hide or read a packet (the OTPC_MR.ADDR field is then locked too preventing to select a packet).

24.5.3.10. "Hardware" Protections

The User area can be protected against read accesses and/or modifications.

To enable the different protections of the User area, the User Configuration special packet must be programmed. The packet is described in the OTPC_UHCxR registers.

As an example, to disable the JTAG interface for an indefinite period, the JTAGDIS, UHCINVDIS and UHCPGDIS fields of the User Hardware Configuration special packet must all be programmed to a non-zero value. Thus, it will be impossible to update or invalidate the User Hardware Configuration special packet.

WARNING "Hardware" protections are in effect for an indefinite period and cannot be cancelled.

24.5.4. OTP Emulation Mode

The OTPC features an Emulation mode. This Emulation mode can be used to test all the operations allowed by the controller on a memory instead of the real OTP memory.

When Emulation mode is enabled, the controller has the same behavior. The Emulation mode is enabled only when the OTP memory has not been previously programmed.

To enable/disable Emulation mode on the User area, follow the steps below:

1. Set OTPC_MR.EMUL to '1' (to enable) or to '0' (to disable).
2. Refresh the User area by writing a '1' to OTPC_CR.REFRESH and 0x7167 in OTPC_CR.KEY.
3. Wait for the refresh completion by polling OTPC_ISR.EORF.

The current running mode of the User area can be observed by reading OTPC_SR.EMUL. If EMUL is set to '1', Emulation mode is enabled; if it is set to '0', Emulation mode is disabled.

After a reset, Emulation mode is disabled.

24.5.5. Interrupts

An OTPC interrupt request can be triggered when one or several of the following bits are set in the OTPC Interrupt Status register (OTPC_ISR): End Of Programming (EOP), End Of Locking (EOL), End Of Invalidation (EOI), End Of Key Transfer (EOKT), Programming Error (PGERR), Locking Error (LKERR), Invalidation Error (IVERR), Write Error (WERR), End Of Read (EOR), End Of Flush (EOF), End Of Hide (EOH), End Of Refresh (EORF), Checksum Check Error (CKERR) or Key Invalid Error (KBERR).

The interrupt request is generated if the corresponding bit in the OTPC Interrupt Mask register (OTPC_IMR) is set. Bits in OTPC_IMR are set by writing a '1' to the corresponding bit in the OTPC Interrupt Enable register (OTPC_IER) and cleared by writing a '1' to the corresponding bit in the OTPC

© 2026 Microchip Technology Inc. and its subsidiaries

Interrupt Disable register (OTPC_IDR). The interrupt request remains active until the corresponding bit in OTPC_ISR is cleared.

Reading the OTPC_ISR clears all bits of the register.

24.5.6. Register Write Protection

To prevent any single software error from corrupting the OTPC behavior, certain registers in the address space can be write-protected by setting the Write Protection Configuration Enable (WPCFEN), Write Protection Interrupt Enable (WPITEN) and/or Write Protection Control Enable (WPCTEN) bit(s) in the Write Protection Mode Register (OTPC_WPMR).

If a write access to the protected registers is detected, the Write Protection Violation Status (WPVS) flag in the Write Protection Status Register (OTPC_WPSR) is set and the field Write Protection Violation Source (WPVSRC) indicates the register in which the write access has been attempted. An interrupt can be raised if the Security and/or Safety Event (SECE) interrupt is set in OTPC_IMR.

The WPVS flag is automatically reset by reading the OTPC_WPSR.

The following registers can be write-protected with the OTPC_WPMR.WPCFEN bit:

- OTPC Mode Register

The following registers can be write-protected with the OTPC_WPMR.WPITEN bit:

- OTPC Interrupt Enable Register
- OTPC Interrupt Disable Register

The following registers can be write-protected with the OTPC_WPMR.WPCTEN bit:

- OTPC Control Register

24.6.1. OTPC Control Register

Name: OTPC_CR
Offset: 0x00
Reset: –
Property: Write-only

This register can only be written if the WPCTEN bit is cleared in the OTPC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	KEY[15:8]							
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit	23	22	21	20	19	18	17	16
	KEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit	15	14	13	12	11	10	9	8
	REFRESH			REPAIR			KBSTOP	KBSTART
Access	W			W			W	W
Reset	–			–			–	–

Bit	7	6	5	4	3	2	1	0
	FLUSH	READ		HIDE		INVLD	CKSGEN	PGM
Access	W	W		W		W	W	W
Reset	–	–		–		–	–	–

Bits 31:16 – KEY[15:0] Programming Key
This field must be written with the correct key code (0x7167) to allow programming, checksum generation, packet invalidation or packet hiding. To start a live repair, the key code must be 0x7364.

Bit 15 – REFRESH Refresh the Area

Value	Description
0	No effect.
1	Starts a refresh of the area.

Bit 12 – REPAIR Live Repair

Value	Description
0	No effect.
1	Starts OTP Live Repair.

Bit 9 – KBSTOP Key Bus Transfer Stop

Value	Description
0	No effect.
1	Stops an on-going transfer on the host key bus.

Bit 8 – KBSTART Key Bus Transfer Start

Value	Description
0	No effect.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	Starts a transfer through the host key bus.

Bit 7 – FLUSH Flush Temporary Registers

Value	Description
0	No effect.
1	Starts a flush of the temporary registers used to store the packet payload.

Bit 6 – READ Read Packet

Value	Description
0	No effect.
1	Starts a read sequence of the selected packet.

Bit 4 – HIDE Hide Packet

Value	Description
0	No effect.
1	The selected packet is not readable anymore until the next reset.

Bit 2 – INVLD Invalidate Packet

Value	Description
0	No effect.
1	Invalidates the selected packet.

Bit 1 – CKSGEN Generate Checksum

Value	Description
0	No effect.
1	Generates and programs the selected packet checksum. This action also locks the packet.

Bit 0 – PGM Program Packet

Value	Description
0	No effect.
1	The selected packet is written.

© 2026 Microchip Technology Inc. and its subsidiaries

24.6.2. OTPC Mode Register

Name: OTPC_MR
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPCFEN bit is cleared in the OTPC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	ADDR[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	ADDR[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	LOCK			KBDST			WRDIS	RDDIS
Access	R/W			R/W			R/W	R/W
Reset	0			0			0	0

Bit	7	6	5	4	3	2	1	0
	EMUL			NPCKT				UHCRRDIS
Access	R/W			R/W				R/W
Reset	0			0				0

Bits 31:16 – ADDR[15:0] Address
This field represents the address of the packet's header.

Bit 15 – LOCK Lock Register
The LOCK bit is set-only. Only a reset can disable lock.

Value	Description
0	The OTPC_MR register is unlocked; write access changes its value.
1	The OTPC_MR register is locked; write access does not change its value.

Bit 12 – KBDST Key Bus Destination

Value	Name	Description
0	TDES	The TDES is the destination of the key transfer.
1	AES	The AES is the destination of the key transfer.

Bit 9 – WRDIS Write Disable

Value	Description
0	The write capability of the OTPC_DR register is enabled.
1	The write capability of the OTPC_DR register is disabled.

Bit 8 – RDDIS Read Disable

Value	Description
0	The read capability of the OTPC_HR and OTPC_DR registers are enabled.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	The read capability of the OTPC_HR and OTPC_DR registers are disabled. In case of read, the returned value is 0.

Bit 7 – EMUL Emulation Enable

Value	Description
0	The Emulation mode of the User area is disabled, all accesses are computed in the OTP memory.
1	The Emulation mode of the User area is enabled, all accesses are computed in the Emulation memory.

Bit 4 – NPCKT New Packet

Value	Description
0	Updates the packet defined at the ADDR address.
1	Creates a new packet.

Bit 0 – UHCRRDIS User Hardware Configuration Register Read Disable

Value	Description
0	The User Hardware Configuration register can be read through the User Interface.
1	The User Hardware Configuration register cannot be read through the User Interface.

© 2026 Microchip Technology Inc. and its subsidiaries

24.6.3. OTPC Address Register

Name: OTPC_AR
Offset: 0x08
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								R/W
Reset								0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	DADDR[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 16 – INCRT Increment Type

Value	Name	Description
0	AFTER_READ	Increment DADDR after a read of OTPC_DR.
1	AFTER_WRITE	Increment DADDR after a write of OTPC_DR.

Bits 7:0 – DADDR[7:0] Data Address
This field represents the word address of the payload to access through the OTPC_DR register.

© 2026 Microchip Technology Inc. and its subsidiaries

24.6.4. OTPC Status Register

Name: OTPC_SR
Offset: 0x0C
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	MNT						ONEF	HIDE
Access	R						R	R
Reset	0						0	0

Bit	7	6	5	4	3	2	1	0
	FLUSH	READ	SKBB	MKBB	EMUL	INVLD	LOCK	PGM
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit 15 – MNT Maintenance On-Going

Value	Description
0	The OTP live repair is not running.
1	The OTP live repair is running. The OTP maintenance is running.

Bit 9 – ONEF One Found

Value	Description
0	No bit at '1' found during the last packet read.
1	At least one '1' has been found during the last packet read.

Bit 8 – HIDE Hiding On-Going

Value	Description
0	No packet hiding is on-going.
1	A packet hiding is on-going.

Bit 7 – FLUSH Flush On-Going

Value	Description
0	The temporary registers are not flushed.
1	The temporary registers are being flushed.

Bit 6 – READ Read On-Going

Value	Description
0	No packet read is on-going.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	A packet read is on-going.

Bit 5 – SKBB Client Key Bus Busy

Value	Description
0	The client key bus is not busy.
1	The client key bus is busy.

Bit 4 – MKBB Host Key Bus Busy

Value	Description
0	The host key bus is not busy.
1	The host key bus is busy.

Bit 3 – EMUL Emulation Enabled

Value	Description
0	The User area Emulation mode is disabled.
1	The User area Emulation mode is enabled.

Bit 2 – INVLD Invalidation On-Going

Value	Description
0	No packet invalidation is on-going.
1	A packet invalidation is on-going.

Bit 1 – LOCK Lock On-Going

Value	Description
0	No packet locking is on-going.
1	A packet locking is on-going.

Bit 0 – PGM Programming On-Going

Value	Description
0	No packet programming is on-going.
1	A packet programming is on-going.

© 2026 Microchip Technology Inc. and its subsidiaries

24.6.5. OTPC Interrupt Enable Register

Name: OTPC_IER
Offset: 0x10
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the OTPC Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
				SECE				
Access				W				
Reset				–				

Bit	23	22	21	20	19	18	17	16
								KBERR
Access								W
Reset								–

Bit	15	14	13	12	11	10	9	8
		HDERR	COERR	CKERR	EORF	EOH	EOF	EOR
Access		W	W	W	W	W	W	W
Reset		–	–	–	–	–	–	–

Bit	7	6	5	4	3	2	1	0
	WERR	IVERR	LKERR	PGERR	EOKT	EOI	EOL	EOP
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit 28 – SECE Security and/or Safety Event Interrupt Enable

Bit 16 – KBERR Key Bus Error Interrupt Enable

Bit 14 – HDERR Hide Error Interrupt Enable

Bit 13 – COERR Corruption Error Interrupt Enable

Bit 12 – CKERR Checksum Check Error Interrupt Enable

Bit 11 – EORF End Of Refresh Interrupt Enable

Bit 10 – EOH End Of Hide Interrupt Enable

Bit 9 – EOF End Of Flush Interrupt Enable

Bit 8 – EOR End Of Read Interrupt Enable

Bit 7 – WERR Write Error Interrupt Enable

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 6 – IVERR Invalidation Error Interrupt Enable

Bit 5 – LKERR Locking Error Interrupt Enable

Bit 4 – PGERR Programming Error Interrupt Enable

Bit 3 – EOKT End Of Key Transfer Interrupt Enable

Bit 2 – EOI End Of Invalidation Interrupt Enable

Bit 1 – EOL End Of Locking Interrupt Enable

Bit 0 – EOP End Of Programming Interrupt Enable

© 2026 Microchip Technology Inc. and its subsidiaries

24.6.6. OTPC Interrupt Disable Register

Name: OTPC_IDR
Offset: 0x14
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the OTPC Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
				SECE				
Access				W				
Reset				–				

Bit	23	22	21	20	19	18	17	16
								KBERR
Access								W
Reset								–

Bit	15	14	13	12	11	10	9	8
		HDERR	COERR	CKERR	EORF	EOH	EOF	EOR

	WERR	IVERR	LKERR	PGERR	EOKT	EOI	EOL	EOP
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit 28 – SECE Security and/or Safety Event (cleared on read)

Value	Description
0	No security or safety event occurred since the last read of OTPC_ISR.
1	One or more safety or security event occurred since the last read of OTPC_ISR. For details on the event, see OTPC_WPSR.

Bit 16 – KBERR Key Bus Error (cleared on read)

Value	Description
0	No error happened on the key bus since the last read of OTPC_ISR.
1	An error happened on the key bus since the last read of OTPC_ISR.

Bit 14 – HDERR Hide Error (cleared on read)

Value	Description
0	No hiding error occurred since the last read of OTPC_ISR.
1	A hiding error occurred since the last read of OTPC_ISR.

Bit 13 – COERR Corruption Error (cleared on read)

Value	Description
0	No corruption occurred during the last start-up since the last read of OTPC_ISR.
1	A corruption occurred since the last read of OTPC_ISR.

Bit 12 – CKERR Checksum Check Error (cleared on read)

Value	Description
0	No checksum check failure occurred during last reading sequence since the last read of OTPC_ISR.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	A checksum check failure occurred since the last read of OTPC_ISR.

Bit 11 – EORF End Of Refresh (cleared on read)

Value	Description
0	No refresh sequence completion since the last read of OTPC_ISR.
1	At least one refresh sequence completion since the last read of OTPC_ISR.

Bit 10 – EOH End Of Hide (cleared on read)

Value	Description
0	No hiding sequence completion since the last read of OTPC_ISR.
1	At least one hiding sequence completion since the last read of OTPC_ISR.

Bit 9 – EOF End Of Flush (cleared on read)

Value	Description
0	No flush of the temporary registers since the last read of OTPC_ISR.
1	At least one flush hof the temporary registers has been completed since the last read of OTPC_ISR.

Bit 8 – EOR End Of Read (cleared on read)

Value	Description
0	No reading sequence completion since the last read of OTPC_ISR.
1	At least one reading sequence completion since the last read of OTPC_ISR.

Bit 7 – WERR Write Error (cleared on read)

Value	Description
0	No write error occurred since the last read of OTPC_ISR.
1	A write error occurred since the last read of OTPC_ISR.

Bit 6 – IVERR Invalidation Error (cleared on read)

Value	Description
0	No invalidation failure occurred during last invalidation sequence since the last read of OTPC_ISR.
1	An invalidation failure occurred since the last read of OTPC_ISR.

Bit 5 – LKERR Locking Error (cleared on read)

Value	Description
0	No locking failure occurred during last locking sequence since the last read of OTPC_ISR.
1	A locking failure occurred since the last read of OTPC_ISR.

Bit 4 – PGERR Programming Error (cleared on read)

Value	Description
0	No programming failure occurred during last programming sequence since the last read of OTPC_ISR.
1	A programming failure occurred since the last read of OTPC_ISR.

Bit 3 – EOKT End Of Key Transfer (cleared on read)

Value	Description
0	No key transfer completion since the last read of OTPC_ISR.
1	At least one key transfer has been completed on the host key bus since the last read of OTPC_ISR.

Bit 2 – EOI End Of Invalidation (cleared on read)

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	No invalidation sequence completion since the last read of OTPC_ISR.
1	At least one invalidation sequence completion since the last read of OTPC_ISR.

Bit 1 – EOL End Of Locking (cleared on read)

Value	Description
0	No locking sequence completion since the last read of OTPC_ISR.
1	At least one locking sequence completion since the last read of OTPC_ISR.

Bit 0 – EOP End Of Programming (cleared on read)

Value	Description
0	No programming sequence completion since the last read of OTPC_ISR.
1	At least one programming sequence completion since the last read of OTPC_ISR.

© 2026 Microchip Technology Inc. and its subsidiaries

24.6.9. OTPC Header Register

Name: OTPC_HR
Offset: 0x20
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	CHECKSUM[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	CHECKSUM[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	SIZE[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	ONE		INVLD[1:0]		LOCK	PACKET[2:0]		
Access	R/W		R/W	R/W	R/W	R/W	R/W	R/W
Reset	0		0	0	0	0	0	0

Bits 31:16 – CHECKSUM[15:0] Packet Checksum
When CHECKSUM is read as 0, the checksum has not been generated. It is still possible to modify the packet content.
When CHECKSUM is read as 0x33CC, the checksum has not been generated but has already some bit at 1. Locking the packet may fail.
When CHECKSUM is read as 0xA5A5, the checksum has been generated and the last check was successful. It is impossible to modify the packet content.
When CHECKSUM is read as 0xCC33, the packet header is corrupted.
When CHECKSUM is read as 0xFFFF, the entire packet is no longer valid. It is possible to modify the packet content and it is up to the software to program the payload to a different value if needed.
For all other values of CHECKSUM, the checksum has been generated and the last check failed to match the checksum written in the OTP. It is impossible to modify the packet content.
This field is not writeable and is set by the OTPC during a lock request.

Bits 15:8 – SIZE[7:0] Packet Size
This field represents the size of the packet payload.
This field is writeable only for new packets.

Bit 7 – ONE One
This field is set to 1 by hardware and is not writeable.

Bits 5:4 – INVLD[1:0] Invalid Status
If set to value 3, this field indicates that the packet is not valid.
This field is not writeable and is set by the OTPC during an invalidation request.

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 3 – LOCK Lock Status
This field is not writeable and is set by the OTPC during a lock request.

Value	Description
0	The packet is not locked.
1	The packet is locked.

Bits 2:0 – PACKET[2:0] Packet Type
This field is writeable only for new packets.

Value	Name	Description
1	REGULAR	Regular packet accessible through the user interface
2	KEY	Key packet accessible only through the Key Buses
3	BOOT_CONFIGURATION	Boot Configuration packet
4	SECURE_BOOT_CONFIGURATION	Secure Boot Configuration packet
5	HARDWARE_CONFIGURATION	Hardware Configuration packet
6	CUSTOM	Custom packet

© 2026 Microchip Technology Inc. and its subsidiaries

24.6.10. OTPC Data Register

Name: OTPC_DR
Offset: 0x24
Reset: 0x00000000
Property: Read/Write

Bits 31:16 – KEY[15:0] Programming Key
This field must be written with the correct key code (0x7364) to change the register value. This field cannot be read.

Bit 4 – EN Automatic Live Repair Enable

Value	Description
0	The automatic start of the OTP live repair is disabled.
1	The automatic start of the OTP live repair is enabled.

Bits 1:0 – FREQ[1:0] Automatic Live Repair Frequency

Value	Name	Description
0	ONE_DAY	The live repair is started every day.
1	FOUR_DAYS	The live repair is started every 4 days.
2	EIGHT_DAYS	The live repair is started every 8 days.
3	SIXTEEN_DAYS	The live repair is started every 16 days.

Bit 17 – URFDIS User Refresh Disable

Value	Description
0	The OTPC_CR.REFRESH bit is fully functional.
1	The OTPC_CR.REFRESH bit is only functional in Emulation mode.

Bit 16 – CPGDIS Custom Packet Program Disable

Value	Description
0	The programming of Custom Special Packet is allowed.
1	The programming of Custom Special Packet is forbidden.

Bit 15 – CLKDIS Custom Packet Lock Disable

Value	Description
0	The generation of the checksum (lock) of the Custom Special Packet is allowed.
1	The generation of the checksum (lock) of the Custom Special Packet is forbidden.

Bit 14 – CINVDIS Custom Packet Invalidation Disable

Value	Description
0	The invalidation of the Custom Special Packet is allowed.
1	The invalidation of the Custom Special Packet is forbidden.

Bit 10 – SBCPGDIS Secure Boot Configuration Packet Program Disable

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	The programming of Secure Boot Configuration Special Packet is allowed.
1	The programming of Secure Boot Configuration Special Packet is forbidden.

Bit 9 – SBCLKDIS Secure Boot Configuration Packet Lock Disable

Value	Description
0	The generation of the checksum (lock) of the Secure Boot Configuration Special Packet is allowed.
1	The generation of the checksum (lock) of the Secure Boot Configuration Special Packet is forbidden.

Bit 8 – SBCINVDIS Secure Boot Configuration Packet Invalidation Disable

Value	Description
0	The invalidation of the Secure Boot Configuration Special Packet is allowed.
1	The invalidation of the Secure Boot Configuration Special Packet is forbidden.

Bit 7 – BCPGDIS Boot Configuration Packet Program Disable

Value	Description
0	The programming of Boot Configuration Special Packet is allowed.
1	The programming of Boot Configuration Special Packet is forbidden.

Bit 6 – BCLKDIS Boot Configuration Packet Lock Disable

Value	Description
0	The generation of the checksum (lock) of the Boot Configuration Special Packet is allowed.
1	The generation of the checksum (lock) of the Boot Configuration Special Packet is forbidden.

Bit 5 – BCINVDIS Boot Configuration Packet Invalidation Disable

Value	Description
0	The invalidation of the Boot Configuration Special Packet is allowed.
1	The invalidation of the Boot Configuration Special Packet is forbidden.

Bit 4 – UHCPGDIS User Hardware Configuration Packet Program Disable

Value	Description
0	The programming of User Hardware Configuration Special Packet is allowed.
1	The programming of User Hardware Configuration Special Packet is forbidden.

Bit 3 – UHCLKDIS User Hardware Configuration Packet Lock Disable

Value	Description
0	The generation of the checksum (lock) of the User Hardware Configuration Special Packet is allowed.
1	The generation of the checksum (lock) of the User Hardware Configuration Special Packet is forbidden.

Bit 2 – UHCINVDIS User Hardware Configuration Packet Invalidation Disable

Value	Description
0	The invalidation of the User Hardware Configuration Special Packet is allowed.
1	The invalidation of the User Hardware Configuration Special Packet is forbidden.

Bit 1 – UPGDIS User programming Disable

Value	Description
0	The OTPC_CR.PGM bit is fully functional.
1	The OTPC_CR.PGM bit is not functional.

Bit 0 – URDDIS User Read Disable

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	The OTPC_CR.READ bit is fully functional.
1	The OTPC_CR.READ bit is not functional.

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x4F5450	PASSWD	Writing any other value in this field aborts the write operation. Always reads as 0.

Bit 4 – FIRSTE First Error Report Enable

Value	Description
0	The last write protection violation source is reported in OTPC_WPSR.WPVSRC and the last software control error type is reported in OTPC_WPSR.SWETYP; The OTPC_ISR.SECE flag is set at the first error occurrence within a series.
1	Only the first write protection violation source is reported in OTPC_WPSR.WPVSRC and only the first software control error type is reported in OTPC_WPSR.SWETYP. The OTPC_ISR.SECE flag is set at the first error occurrence within a series.

Bit 2 – WPCTEN Write Protection Control Enable

Value	Description
0	Disables the write protection of the control if WPKEY matches to 0x4F5450 (OTP in ASCII).
1	Enables the write protection of the control if WPKEY matches to 0x4F5450 (OTP in ASCII).

Bit 1 – WPITEN Write Protection Interrupt Enable

Value	Description
0	Disables the write protection of the interruption configuration if WPKEY matches to 0x4F5450 (OTP in ASCII).
1	Enables the write protection of the interruption configuration if WPKEY matches to 0x4F5450 (OTP in ASCII).

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 0 – WPCFEN Write Protection Configuration Enable

Value	Description
0	Disables the write protection of the configuration if WPKEY matches to 0x4F5450 (OTP in ASCII).
1	Enables the write protection of the configuration if WPKEY matches to 0x4F5450 (OTP in ASCII).

Bit 31 – ECLASS Software Error Class

Value	Name	Description
0	WARNING	An abnormal access that does not have any impact.
1	ERROR	An abnormal access that may have an impact.

Bits 27:24 – SWETYP[3:0] Software Error Type

Value	Name	Description
0	READ_WO	A write-only register has been read (warning).
1	WRITE_RO	A write access has been performed on a read-only register (warning).
2	CONF_CHG	A change has been made into the configuration (error).
3	KEY_ERROR	A write has been computed in OTPC_CR or OTPC_WPMR register with a wrong value in the related KEY field (error).
4	DATA_ACC	The non-secure world application tried to read a packet from the secure world (error).

Bits 23:8 – WPVSRC[15:0] Write Protection Violation Source
When WPVS = 1, WPVSRC indicates the register address offset at which a write access has been attempted.

Bit 3 – SWE Software Control Error (cleared on read)

Value	Description
0	No software error has occurred since the last read of OTPC_WPSR.
1	A software error has occurred since the last read of OTPC_WPSR. The field SWETYP details the type of software error encountered.

Bit 2 – SEQE Internal Sequencer Error (cleared on read)

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	No peripheral internal sequencer error has occurred since the last read of OTPC_WPSR.
1	A peripheral internal sequencer error has occurred since the last read of OTPC_WPSR. This flag can be set under abnormal operating conditions.

Bit 1 – CGD Clock Glitch Detected (cleared on read)

Value	Description
0	No clock glitch has occurred since the last read of OTPC_WPSR.
1	A clock glitch has occurred since the last read of OTPC_WPSR. This flag can be set under abnormal operating conditions.

Bit 0 – WPVS Write Protection Violation Status (cleared on read)

Value	Description
0	No write protection violation has occurred since the last read of OTPC_WPSR.
1	A write protection violation has occurred since the last read of OTPC_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into WPVSRC.

System Controller

25. Overview

25.1. Block Diagram

Figure 25.1. System Controller Block Diagram

© 2026 Microchip Technology Inc. and its subsidiaries

25.2. Components

- Peripherals powered by VDDBU:
  - System Controller Write Protection (SYSCWP)
  - General Purpose Backup Registers (GPBR)
  - Reset Controller (RSTC)
  - Real-time Timer (RTT)
  - Real-time Clock (RTC)
  - Shutdown Controller (SHDWC)
  - Slow Clock Controller (SCKC)
- Peripherals powered by VDDCORE:
  - Watchdog Timer (WDT)
  - Chip Identifier (CHIPID)
  - OTP Memory Controller (OTPC)
  - Special Function Registers (SFR)
  - Clock Generator and Power Management Controller (PMC)
  - Parallel Input/Output Controller (PIO)
  - Periodic Interval Timer (PIT)

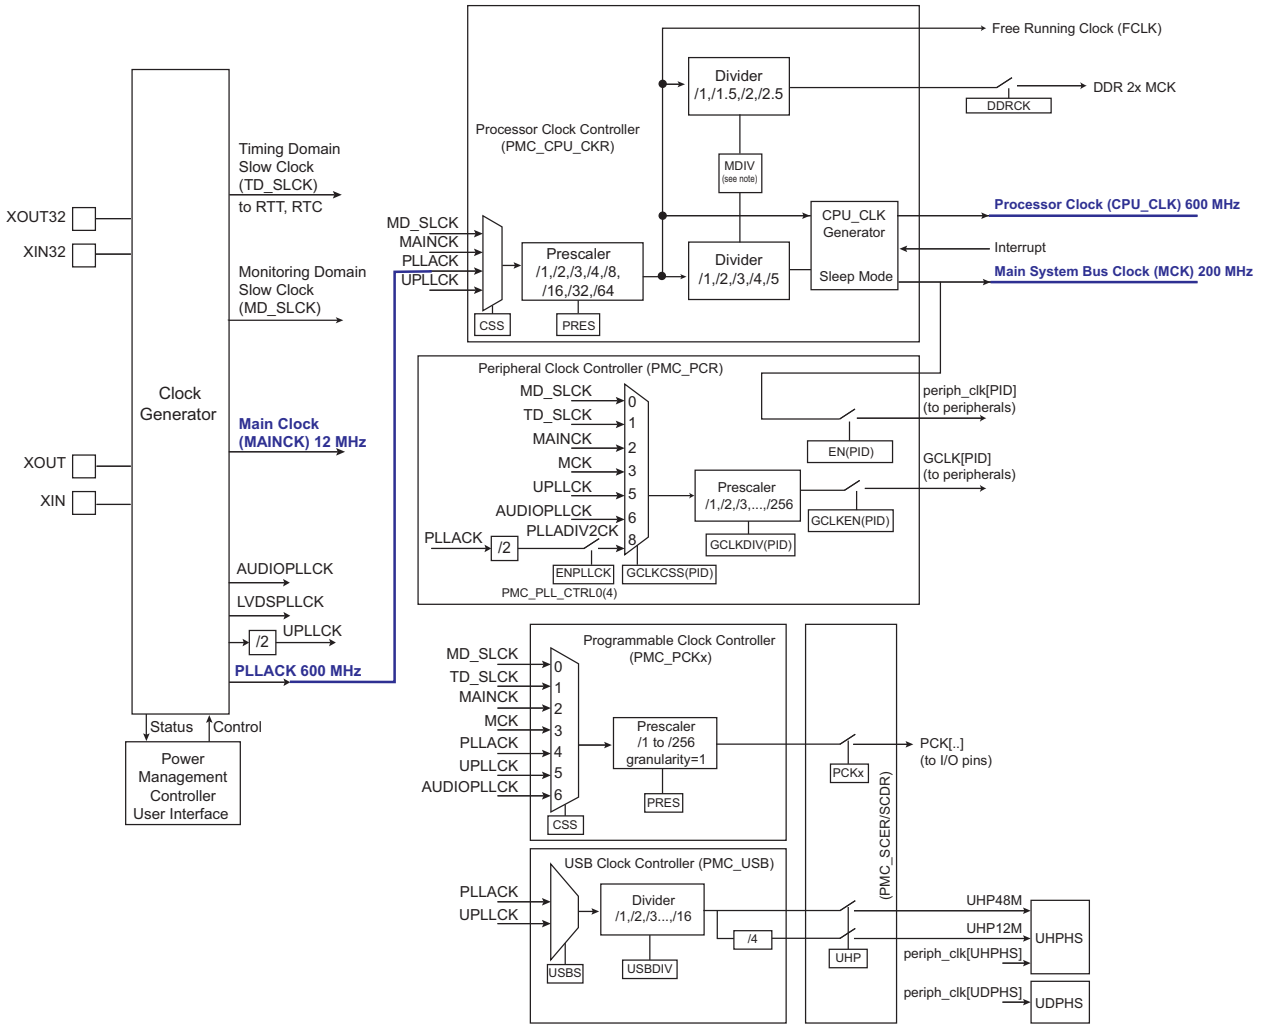
25.3. Product Dependencies

25.3.1. Clocks

The system controller peripherals are always on, except:

- Parallel Input/Output Controllers (PIOs) that have one clock control (PIOA) for all PIO controllers
- Special Function Registers (SFR)
- Periodic Interval Timer (PIT)

25.3.2. Changing System Frequencies



After ROM code execution, the system clock is set as follows:

- MAINCK is fed by the main RC oscillator, i.e., 12 MHz.
- PLLA is set to 1.2 GHz.
- CPU_CLK is set to 600 MHz.
- MCK is set to 200 MHz.

This is illustrated in the following figure.

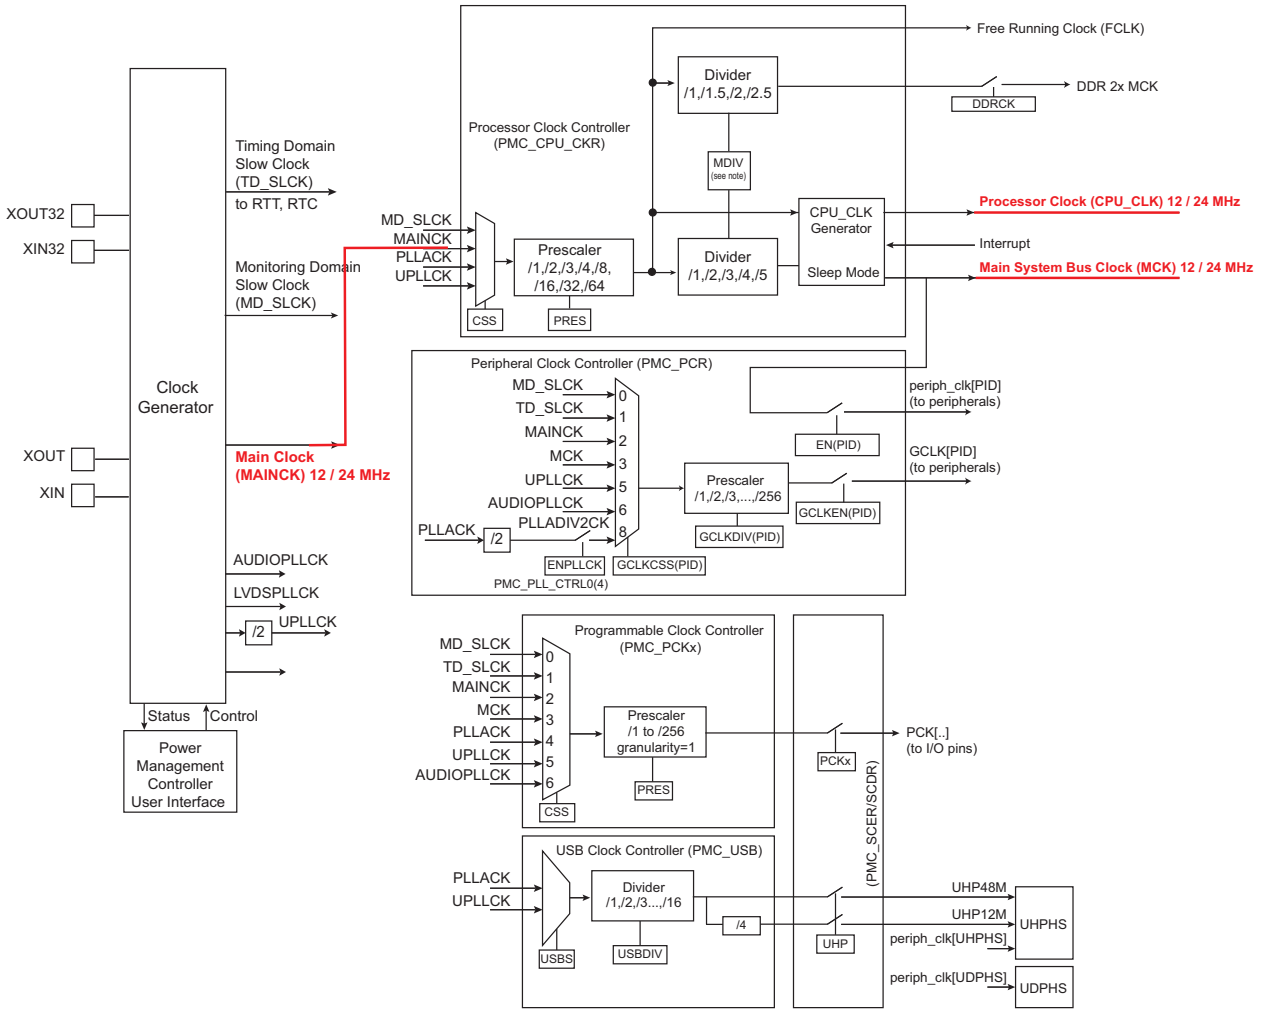
© 2026 Microchip Technology Inc. and its subsidiaries

Figure 25.2. PMC Rom Code Configuration

Note: MDIV should always be different from 0 when using DDR memories. If MDIV must be set to 0, first switch the DDR memories to Self-refresh mode and disable DDRCLK.

To avoid any overclocking during system clock modification, it is recommended to change system frequencies in two steps.

The first step leads to a known and basic intermediate state where all clocks are in a low-frequency range.



For example, the following sequence can be performed:

1. Set MCK to MAINCK, i.e., 12 MHz.
2. Set MAINCK to Crystal Oscillator, typically 24 MHz. MCK then runs at 24 MHz.

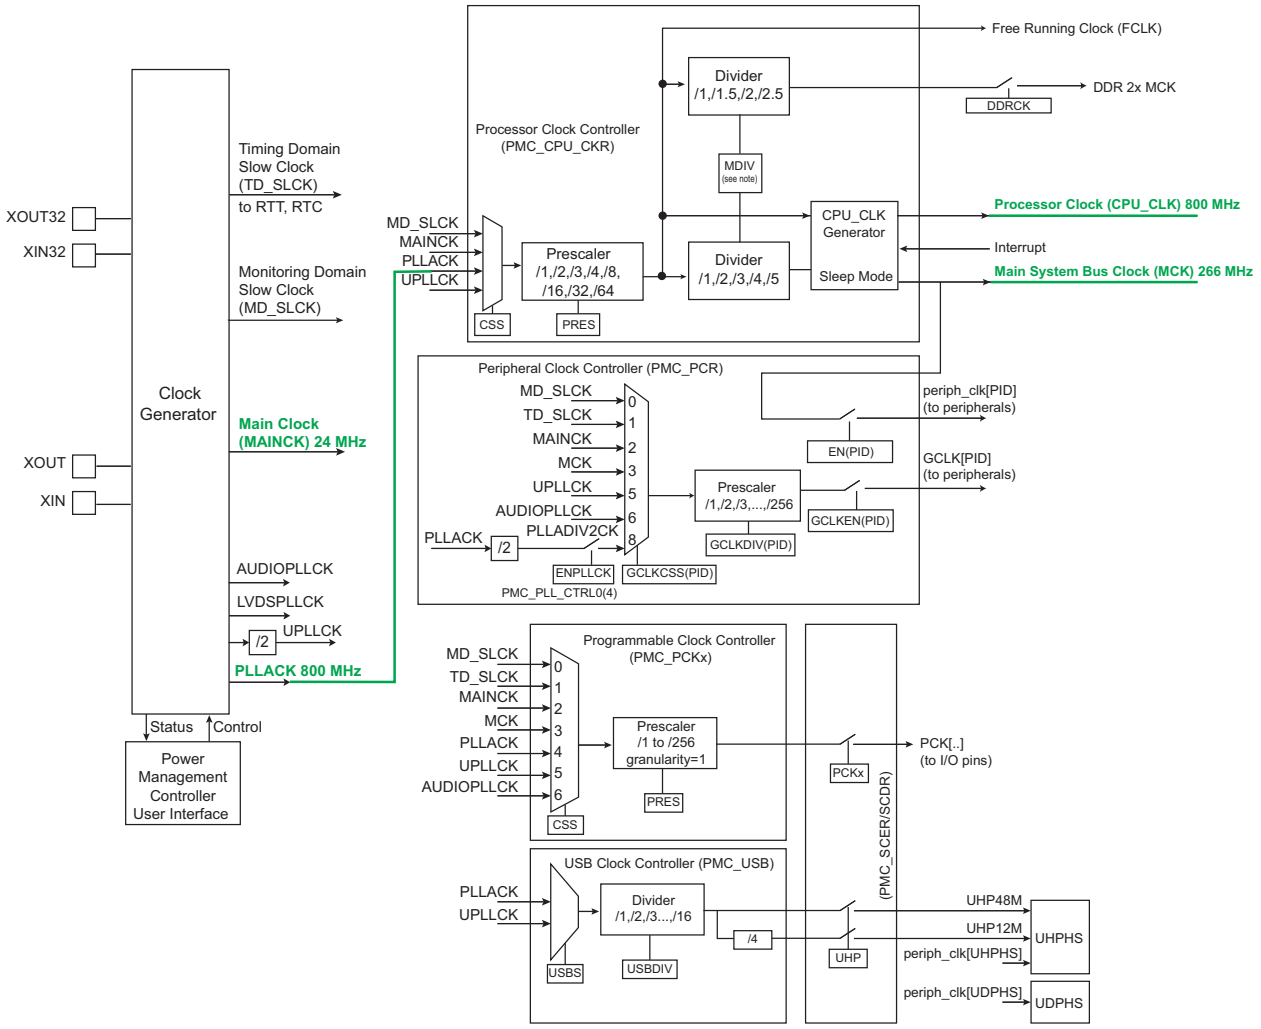
This intermediate state is illustrated in the following figure.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 25.3. PMC Intermediate Configuration

Note: MDIV should always be different from 0 when using DDR memories. If MDIV must be set to 0, first switch the DDR memories to Self-refresh mode and disable DDRCLK.

The second step leads to the final expected state.



Perform the following sequence:

1. Set PLL to 1.6 GHz, and set PLLACK to 800 MHz.
2. Set CPU_CLK to 800 MHz.
3. Set MCK to CPU_CLK/3, i.e., 266 MHz.

The final state is illustrated in the following figure.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 25.4. PMC Final Configuration

Note: MDIV should always be different from 0 when using DDR memories. If MDIV must be set to 0, first switch the DDR memories to Self-refresh mode and disable DDRCLK.

25.3.3. Interrupts

Each peripheral has its own interrupt ID, except CHIP_ID, SYSCWP and GPBR, that have no interrupt line.

25.3.4. Reset

System controller peripherals are connected to the processor and peripherals reset line.

25.3.5. I/Os

For the applicable I/O type and power supply, refer to the table Pin Description.

25.3.6. Power Supplies

The 32.768 kHz crystal oscillator and the slow RC oscillator are powered by VDDBU.

The main crystal oscillator, the main RC oscillator, PLLA and AUDIOPLL are powered by VDDANA.

LVDSPLL and MIPIPLL are powered by VDDOUT25 (internally or externally).

UPLL is powered by VDDIN33.

26. System Controller Write Protection (SYSCWP)

26.1. Functional Description

26.1.1. System Controller Peripheral Mapping

Table 26.1. System Controller Peripheral Mapping

Offset	System Controller Peripheral	Name
0x000-0x00C	Reset Controller	RSTC
0x010-0x01C	Shutdown Controller	SHDWC
0x020-0x03C	Real Time Timer	RTT
0x040-0x04C	Period Interval Timer	PIT
0x050-0x05C	Slow Clock Controller	SCKC
0x060-0x0A4	General Purpose Backup Registers	GPBR
0x0A8-0xD8	Real Time Clock	RTC
0x0DC	Write Protection Mode Register	SYSC_WPMR
0x0E0	Write Protection Status Register	SYSC_WPSR

26.1.2. Register Write Protection

To prevent any single software error from modifying the configuration of the Reset Controller (RSTC), Shutdown Controller (SHDWC), Real-time Timer (RTT), Periodic Interval Timer (PIT), Slow Clock Controller (SCKC), General Purpose Backup Register (GPBR), Real-time Clock (RTC) and Watchdog Timer (WDT), some registers of these peripherals can be write-protected by setting the WPEN and/or WPITEN bits in the System Controller Write Protection Mode register (SYSC_WPMR).

Note: The WDT embeds additional write protection mechanisms.

When write protection is enabled, any attempt to write these registers is reported in the System Controller Write Protection Status register (SYSC_WPSR).

The following registers can be write-protected when SYSC_WPMR.WPEN=1:

- WDT Control Register
- WDT Mode Register
- RSTC Mode Register
- SHDWC Mode Register
- SHDWC Wakeup Inputs Register
- PIT Mode Register
- SCKC Configuration Register
- RTC Control Register
- RTC Mode Register
- RTC Time Alarm Register
- RTC Calendar Alarm Register
- RTT Mode Register
- RTT Alarm Register
- RTT Modulo Selection Register
- GPBR Full Clear Register
- GPBR Registers

© 2026 Microchip Technology Inc. and its subsidiaries

The following registers can be write-protected when SYSC_WPMR.WPITEN=1:

- RTC Interrupt Enable Register
- RTC Interrupt Disable Register

© 2026 Microchip Technology Inc. and its subsidiaries

26.2. Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0
0x00	SYSC_WPMR	31:24	WPKEY[23:16]							
		23:16	WPKEY[15:8]

26.2.1. SYSC Write Protection Mode Register

Name: SYSC_WPMR
Offset: 0x00
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	WPKEY[23:16]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16
	WPKEY[15:8]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8
	WPKEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
							WPITEN	WPEN
Access							R/W	R/W
Reset							0	0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x535943	PASSWD	Writing any other value in this field aborts the write operation of the WPEN and WPITEN bits. Always reads as 0.

Bit 1 – WPITEN Write Protection RTC Interrupt Enable

Value	Description
0	Disables the write protection of the RTC_IER/RTC_IDR configuration registers if WPKEY corresponds to 0x535943 (“SYC” in ASCII).
1	Enables the write protection of the RTC_IER/RTC_IDR configuration registers if WPKEY corresponds to 0x535943 (“SYC” in ASCII).

Bit 0 – WPEN Write Protection Enable

Value	Description
0	Disables the write protection of the configuration registers if WPKEY corresponds to 0x535943 (“SYC” in ASCII).
1	Enables the write protection of the configuration registers if WPKEY corresponds to 0x535943 (“SYC” in ASCII).

© 2026 Microchip Technology Inc. and its subsidiaries

26.2.2. SYSC Write Protection Status Register

Name: SYSC_WPSR
Offset: 0x04
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	WVSRC[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
								WPVS
Access								R
Reset								0

Bits 15:8 – WVSRC[7:0] Write Violation Source
When bit WPVS is equal to 1, the field WVSRC indicates the register address offset at which a write access has been attempted.

Bit 0 – WPVS Write Protection Register Violation Status
WDT_CR, WDT_MR, RTT_MODR, RTC_IDR and RTC_IER can be write-protected but WPVS does not report any violation for these registers.

Value	Description
0	No write protection violation has occurred since the last read of SYSC_WPSR.
1	A write protection violation has occurred since the last read of SYSC_WPSR. The associated violation is reported into field WVSRC.

27. Advanced Interrupt Controller (AIC)

27.1. Description

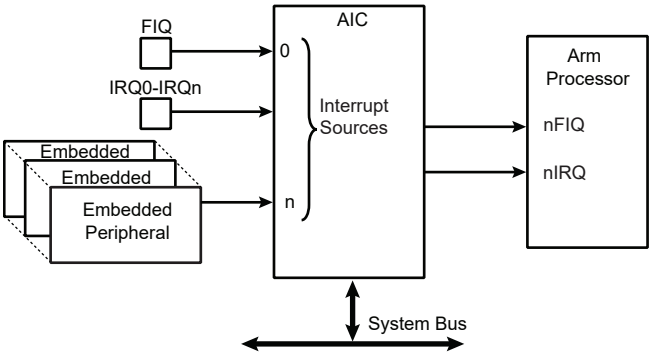
The Advanced Interrupt Controller (AIC) is an 8-level priority, individually maskable, vectored interrupt controller providing handling of up to one hundred and twenty-eight interrupt sources. It is designed to substantially reduce the software and real-time overhead in handling internal and external interrupts.

The AIC drives the nFIQ (fast interrupt request) and the nIRQ (standard interrupt request) inputs of an Arm processor. Inputs of the AIC are either internal peripheral interrupts or external interrupts coming from the product's pins.

The 8-level Priority Controller allows the user to define the priority for each interrupt source, thus permitting higher priority interrupts to be serviced even if a lower priority interrupt is being processed.

Internal interrupt sources can be programmed to be level-sensitive or edge-triggered. External interrupt sources can be programmed to be rising-edge or falling-edge triggered or high-level or low-level sensitive.

The fast-forcing feature redirects any internal or external interrupt source to provide a fast interrupt rather than a normal interrupt.



27.2. Embedded Characteristics

- Controls the Interrupt Lines (nIRQ and nFIQ) of an Arm Processor
- 61 Individually Maskable and Vectored Interrupt Sources
  - Source 0 is reserved for the fast interrupt input (FIQ)
  - Source 1 is reserved for system peripheral interrupts
  - Source 2 to Source 60 control up to 126 embedded peripheral interrupts or external interrupts
  - Programmable edge-triggered or level-sensitive internal sources
  - Programmable rising/falling edge-triggered or high/low level-sensitive external sources
- 8-level Priority Controller
  - Drives the normal interrupt of the processor
  - Handles priority of the interrupt sources 1 to 60
  - Higher priority interrupts can be served during service of lower priority interrupt
- Vectoring
  - Optimizes interrupt service routine branch and execution
  - One 32-bit vector register for all interrupt sources
  - Interrupt vector register reads the corresponding current interrupt vector or the current interrupt number
- Protect Mode
  - Easy debugging by preventing automatic operations when protect models are enabled
- Fast Forcing
  - Permits redirecting any normal interrupt source to the fast interrupt of the processor
- General Interrupt Mask
  - Provides processor synchronization on events without triggering an interrupt
- Register Write Protection

27.6. I/O Line Description

Table 27.1. I/O Line Description

Pin Name	Pin Description	Type
FIQ	Fast Interrupt	Input
IRQ0–IRQn	Interrupt 0–Interrupt n	Input

27.7. Product Dependencies

27.7.1. I/O Lines

The interrupt signals FIQ and IRQ0 to IRQn are normally multiplexed through the PIO controllers. Depending on the features of the PIO controller used in the product, the pins must be programmed in accordance with their assigned interrupt functions. This is not applicable when the PIO controller used in the product is transparent on the input path.

27.7.2. Power Management

The AIC is continuously clocked. The Power Management Controller has no effect on the AIC behavior.

The assertion of the AIC outputs, either nIRQ or nFIQ, wakes up the Arm processor while it is in Idle mode. The General Interrupt Mask feature enables the AIC to wake up the processor without asserting the interrupt line of the processor, thus providing synchronization of the processor on an event.

27.7.3. Interrupt Sources

FIQ always drives Interrupt Source 0.

The System Controller interrupt drives Interrupt Source 1.

The System Controller interrupt is the result of the OR-wiring of the System Controller interrupt lines. When a System Controller interrupt occurs, the service routine must first distinguish the cause of the interrupt. This is performed by reading successively the status registers of the System Controller peripherals.

Interrupt sources 2 to 60 can either be connected to the interrupt outputs of an embedded user peripheral, or to external interrupt lines. The external interrupt lines can be connected either directly or through the PIO Controller.

PIO controllers are considered as user peripherals in the scope of interrupt handling. Accordingly, the PIO controller interrupt lines are connected to interrupt sources 2 to 60.

The peripheral identification defined at the product level corresponds to the interrupt source number (as well as the bit number controlling the clock of the peripheral). Consequently, to simplify the description of the functional operations and the user interface, the interrupt sources are named FIQ, SYS, and PID2 to PID60.

27.8. Functional Description

27.8.1. Interrupt Source Control

27.8.1.1. Interrupt Source Mode

The AIC independently programs each interrupt source. The SRCTYPE field of the Source Mode register (AIC_SMR) selects the interrupt condition of the interrupt source selected by the INTSEL field of the Source Select register (AIC_SSR).

Note: Configuration registers such as AIC_SMR and AIC_SSR return the values corresponding to the interrupt source selected by INTSEL.

© 2026 Microchip Technology Inc. and its subsidiaries

The internal interrupt sources wired on the interrupt outputs of the embedded peripherals can be programmed either in Level-Sensitive mode or in Edge-Triggered mode. The active level of the internal interrupts is not important for the user.

The external interrupt sources can be programmed either in High Level-Sensitive or Low Level-Sensitive modes, or in Rising Edge-Triggered or Negative Edge-Triggered modes.

27.8.1.2. Interrupt Source Enabling

Each interrupt source, including the FIQ in source 0, can be enabled or disabled by using the command registers Interrupt Enable Command register (AIC_IECR) and Interrupt Disable Command register (AIC_IDCR). The interrupt mask of the selected interrupt source can be read in the Interrupt Mask register (AIC_IMR). A disabled interrupt does not affect servicing of other interrupts.

27.8.1.3. Interrupt Clearing and Setting

All interrupt sources programmed to be edge-triggered (including the FIQ in source 0) can be individually set or cleared by writing respectively the Interrupt Set Command register (AIC_ISCR) and Interrupt Clear Command register (AIC_ICCR). Clearing or setting interrupt sources programmed in Level-Sensitive mode has no effect.

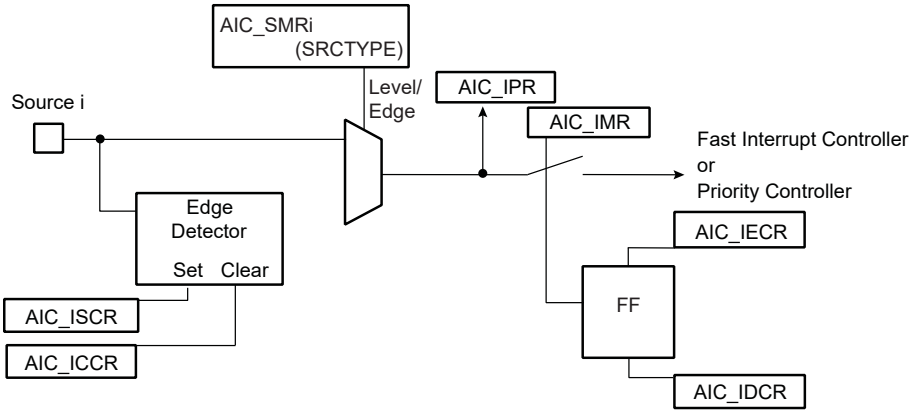
The clear operation is perfunctory, as the software must perform an action to reset the “memorization” circuitry activated when the source is programmed in Edge-Triggered mode. However, the set operation is available for auto-test or software debug purposes. It can also be used to execute an AIC-implementation of a software interrupt.

The AIC features an automatic clear of the current interrupt when AIC_IVR (Interrupt Vector register) is read. Only the interrupt source being detected by the AIC as the current interrupt is affected by this operation. (See the section Priority Controller.) The automatic clear reduces the operations required by the interrupt service routine entry code to read AIC_IVR. Note that the automatic interrupt clear is disabled if the interrupt source has the Fast Forcing feature enabled, as it is considered uniquely as an FIQ source. (For further details, see the section ”Fast Forcing”).

The automatic clear of interrupt source 0 is performed when the FIQ Vector register (AIC_FVR) is read.

27.8.1.4. Interrupt Status

Interrupt Pending registers (AIC_IPR) represent the state of the interrupt lines, whether they are masked or not. AIC_IMR can be used to define the mask of the interrupt lines.



The Interrupt Status register (AIC_ISR) reads the number of the current interrupt (see the section Priority Controller) and the Core Interrupt Status register (AIC_CISR) gives an image of the nIRQ and nFIQ signals driven on the processor.

Each status referred to above can be used to optimize the interrupt handling of the systems.

27.8.1.5.Internal Interrupt Source Input Stage

Figure 27.4. Internal Interrupt Source Input Stage

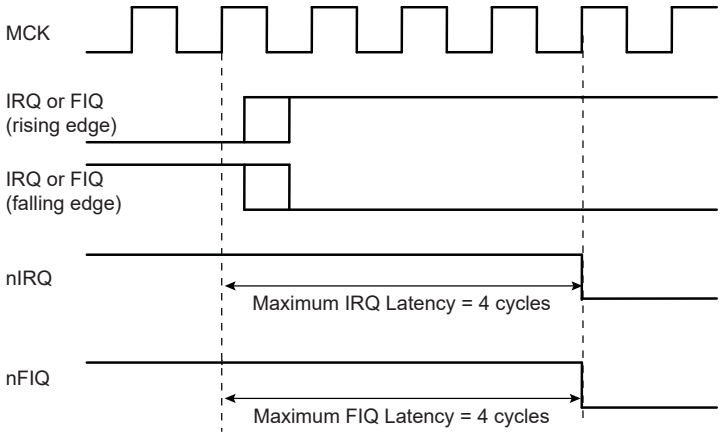
27.8.1.6.External Interrupt Source Input Stage

Figure 27.5. External Interrupt Source Input Stage

27.8.2. Interrupt Latencies

Global interrupt latencies depend on several parameters, including:

- The time the software masks the interrupts
- Occurrence, either at the processor level or at the AIC level
- The execution time of the instruction in progress when the interrupt occurs
- The treatment of higher priority interrupts and the resynchronization of the hardware signals



This section addresses hardware resynchronizations only. It gives details about the latency times between the events on an external interrupt leading to a valid interrupt (edge or level) or the assertion of an internal interrupt source and the assertion of the nIRQ or nFIQ line on the processor. The resynchronization time depends on the programming of the interrupt source and on its type (internal or external). For the standard interrupt, resynchronization times are given assuming there is no higher priority in progress.

The PIO Controller multiplexing has no effect on the interrupt latencies of the external interrupt sources.

27.8.2.4. Internal Interrupt Level Sensitive Source

Figure 27.9. Internal Interrupt Level Sensitive Source

27.8.3. Normal Interrupt

27.8.3.1. Priority Controller

An 8-level priority controller drives the nIRQ line of the processor, depending on the interrupt conditions occurring on the interrupt sources 1 to 60 (except for those programmed in Fast Forcing).

Each interrupt source has a programmable priority level of 7 to 0, which is user-definable by writing AIC_SMR.PRIOR. Level 7 is the highest priority and level 0 the lowest.

As soon as an interrupt condition occurs, as defined by AIC_SMR.SRCTYPE, the nIRQ line is asserted. As a new interrupt condition might have happened on other interrupt sources since the nIRQ has been asserted, the priority controller determines the current interrupt at the time AIC_IVR is read. The read of AIC_IVR is the entry point of the interrupt handling which allows the AIC to consider that the interrupt has been taken into account by the software.

The current priority level is defined as the priority level of the current interrupt.

If several interrupt sources of equal priority are pending and enabled when AIC_IVR is read, the interrupt with the lowest interrupt source number is serviced first.

The nIRQ line can be asserted only if an interrupt condition occurs on an interrupt source with a higher priority. If an interrupt condition happens (or is pending) during the interrupt treatment in progress, it is delayed until the software indicates to the AIC the end of the current service by writing AIC_EOICR (End of Interrupt Command register). The write of AIC_EOICR is the exit point of the interrupt handling.

27.8.3.2. Interrupt Nesting

The priority controller utilizes interrupt nesting in order for the high priority interrupt to be handled during the service of lower priority interrupts. This requires the interrupt service routines of the lower interrupts to re-enable the interrupt at the processor level.

When an interrupt of a higher priority happens during an already occurring interrupt service routine, the nIRQ line is re-asserted. If the interrupt is enabled at the core level, the current execution is interrupted and the new interrupt service routine should read AIC_IVR. At this time, the current interrupt number and its priority level are pushed into an embedded hardware stack, so that they are saved and restored when the higher priority interrupt servicing is finished and AIC_EOICR is written.

The AIC is equipped with an 8-level wide hardware stack in order to support up to eight interrupt nestings to match the eight priority levels.

27.8.3.3. Interrupt Vectoring

The interrupt handler address corresponding to the interrupt source selected by the INTSEL field can be stored in AIC_SVR (Source Vector register). When the processor reads AIC_IVR, the value written into AIC_SVR corresponding to the current interrupt is returned. Optionally, the AIC_IVR

© 2026 Microchip Technology Inc. and its subsidiaries

register can return the current interrupt number instead. This can be defined separately for each interrupt source using the AIC SVR Return Enable Register (AIC_SVRRER) and AIC SVR Return Disable Register (AIC_SVRRDR).

This feature offers a way to branch in one single instruction to the handler corresponding to the current interrupt, as AIC_IVR is mapped at the absolute address 0xFFFFF100 and thus accessible from the Arm interrupt vector at address 0x00000018 through the following instruction:

```
LDR PC,[PC,# -&F20]
```

When the processor executes this instruction, it loads the read value in AIC_IVR in its program counter, thus branching the execution on the correct interrupt handler.

27.8.3.4. Interrupt Handlers

This section gives an overview of the fast interrupt handling sequence when using the AIC. It is assumed that the programmer understands the architecture of the Arm processor, and especially the Processor Interrupt modes and the associated status bits.

It is assumed that:

1. The AIC has been programmed, AIC_SVR registers are loaded with corresponding interrupt service routine addresses and interrupts are enabled.
2. The instruction at the Arm interrupt exception vector address is required to work with the vectoring

   ```
   LDR PC, [PC, # -&F20]
   ```

When nIRQ is asserted, if the bit "I" of CPSR is 0, the sequence is as follows:

1. The CPSR is stored in SPSR_irq, the current value of the Program Counter is loaded in the Interrupt link register (R14_irq) and the Program Counter (R15) is loaded with 0x18. In the following cycle during fetch at address 0x1C, the Arm core adjusts R14_irq, decrementing it by four.
2. The Arm core enters Interrupt mode, if it has not already done so.
3. When the instruction loaded at address 0x18 is executed, the program counter is loaded with the value read in AIC_IVR. Reading AIC_IVR has the following effects:
   - Sets the current interrupt to be the pending and enabled interrupt with the highest priority. The current level is the priority level of the current interrupt.
   - De-asserts the nIRQ line on the processor. Even if vectoring is not used, AIC_IVR must be read in order to de-assert nIRQ.
   - Automatically clears the interrupt, if it has been programmed to be edge-triggered.
   - Pushes the current level and the current interrupt number on to the stack.
   - Returns the value written in AIC_SVR corresponding to the current interrupt.
4. The previous step has the effect of branching to the corresponding interrupt service routine. This should start by saving the link register (R14_irq) and SPSR_IRQ. The link register must be decremented by four when it is saved if it is to be restored directly into the program counter at the end of the interrupt. For example, the instruction `SUB PC, LR, #4` may be used.
5. Further interrupts can then be unmasked by clearing the "I" bit in CPSR, allowing re-assertion of the nIRQ to be taken into account by the core. This can happen if an interrupt with a higher priority than the current interrupt occurs.
6. The interrupt handler can then proceed as required, saving the registers that will be used and restoring them at the end. During this phase, an interrupt of higher priority than the current level will restart the sequence from step 1.
   Note: If the interrupt is programmed to be level-sensitive, the source of the interrupt must be cleared during this phase.

© 2026 Microchip Technology Inc. and its subsidiaries

7. The “I” bit in CPSR must be set in order to mask interrupts before exiting to ensure that the interrupt is completed in an orderly manner.
8. AIC_EOICR must be written in order to indicate to the AIC that the current interrupt is finished. This causes the current level to be popped from the stack, restoring the previous current level if one exists on the stack. If another interrupt is pending, with lower or equal priority than the old current level but with higher priority than the new current level, the nIRQ line is re-asserted, but the interrupt sequence does not immediately start because the “I” bit is set in the core. SPSR_irq is restored. Finally, the saved value of the link register is restored directly into the PC. This has the effect of returning from the interrupt to whatever was being executed before, and of loading the CPSR with the stored SPSR, masking or unmasking the interrupts depending on the state saved in SPSR_irq.
   Note: The “I” bit in SPSR is significant. If it is set, it indicates that the Arm core was on the verge of masking an interrupt when the mask instruction was interrupted. Hence, when SPSR is restored, the mask instruction is completed (interrupt is masked).

27.8.4. Fast Interrupt

27.8.4.1. Fast Interrupt Source

Interrupt source 0 is the only source which can raise a fast interrupt request to the processor except if fast forcing is used. Interrupt source 0 is generally connected to a FIQ pin of the product, either directly or through a PIO Controller.

27.8.4.2. Fast Interrupt Control

The fast interrupt logic of the AIC has no priority controller. The mode of interrupt source 0 is programmed with AIC_SMR and INTSEL = 0; the PRIOR field of this register is not used even if it reads what has been written. AIC_SMR.SRCTYPE enables programming the fast interrupt source to be rising-edge triggered or falling-edge triggered or high-level sensitive or low-level sensitive.

Writing 0x1 in AIC_IECR and AIC_IDCR respectively enables and disables the fast interrupt when INTSEL = 0. Bit 0 of AIC_IMR indicates whether the fast interrupt is enabled or disabled.

27.8.4.3. Fast Interrupt Vectoring

The fast interrupt handler address can be stored through AIC_SVR. The value written into this register when INTSEL = 0 is returned when the processor reads AIC_FVR (FIQ Vector register). This offers a way to branch in one single instruction to the interrupt handler, as AIC_FVR is mapped at the absolute address 0xFFFF F104 and thus accessible from the Arm fast interrupt vector at address 0x0000 001C through the following instruction:

```
LDR PC,[PC,# -&F20]
```

When the processor executes this instruction, it loads the value read in AIC_FVR in its program counter, thus branching the execution on the fast interrupt handler. It also automatically performs the clear of the fast interrupt source if it is programmed in Edge-Triggered mode.

27.8.4.4. Fast Interrupt Handlers

This section gives an overview of the fast interrupt handling sequence when using the AIC. It is assumed that the programmer understands the architecture of the Arm processor, and especially the Processor Interrupt modes and associated status bits.

Assuming that:

1. The AIC has been programmed, AIC_SVR is loaded with the fast interrupt service routine address, and interrupt source 0 is enabled.
2. The Instruction at address 0x1C (FIQ exception vector address) is required to vector the fast interrupt:
   ```
   LDR PC,[PC, # -&F20]
   ```
3. The user does not need nested fast interrupts.

© 2026 Microchip Technology Inc. and its subsidiaries

When nFIQ is asserted, if bit “F” of CPSR is 0, the sequence is:

1. The CPSR is stored in SPSR_fiq, the current value of the program counter is loaded in the FIQ link register (R14_FIQ) and the program counter (R15) is loaded with 0x1C. In the following cycle, during fetch at address 0x20, the Arm core adjusts R14_fiq, decrementing it by four.
2. The Arm core enters FIQ mode.
3. When the instruction loaded at address 0x1C is executed, the program counter is loaded with the value read in AIC_FVR. Reading AIC_FVR has the effect of automatically clearing the fast interrupt, if it has been programmed to be edge-triggered. In this case only, it de-asserts the nFIQ line on the processor.

```
FIQ_Handler_Branch
   mov r14, pc
   bx r0
```

4. The previous step enables branching to the corresponding interrupt service routine. It is not necessary to save the link register R14_fiq and SPSR_fiq if nested fast interrupts are not needed.
5. The Interrupt Handler can then proceed as required. It is not necessary to save registers R8 to R13 because the FIQ mode has its own dedicated registers and registers R8 to R13 are banked. The other registers, R0 to R7, must be saved before being used, and restored at the end (before the next step).
   Note: If the fast interrupt is programmed to be level-sensitive, the source of the interrupt must be cleared during this phase in order to de-assert interrupt source 0.
6. Finally, Link register R14_fiq is restored into the PC after decrementing it by four (with instruction `SUB PC, LR, #4` for example). This has the effect of returning from the interrupt to whatever was being executed before, loading the CPSR with the SPSR and masking or unmasking the fast interrupt depending on the state saved in the SPSR.
   Note: The “F” bit in SPSR is significant. If it is set, it indicates that the Arm core was just about to mask FIQ interrupts when the mask instruction was interrupted. Hence, when the SPSR is restored, the interrupted instruction is completed (FIQ is masked).

Another way to handle the fast interrupt is to map the interrupt service routine at the address of the Arm vector 0x1C. This method does not use vectoring, so that reading AIC_FVR must be performed at the very beginning of the handler operation. However, this method saves the execution of a branch instruction.

27.8.4.5. Fast Forcing

The Fast Forcing feature of the advanced interrupt controller provides redirection of any normal Interrupt source on the fast interrupt controller.

Fast Forcing is enabled or disabled by writing to the Fast Forcing Enable register (AIC_FFER) and the Fast Forcing Disable register (AIC_FFDR). Writing to these registers results in an update of the Fast Forcing Status register (AIC_FFSR) that controls the feature for each internal or external interrupt source.

When Fast Forcing is disabled, the interrupt sources are handled as described in the previous sections.

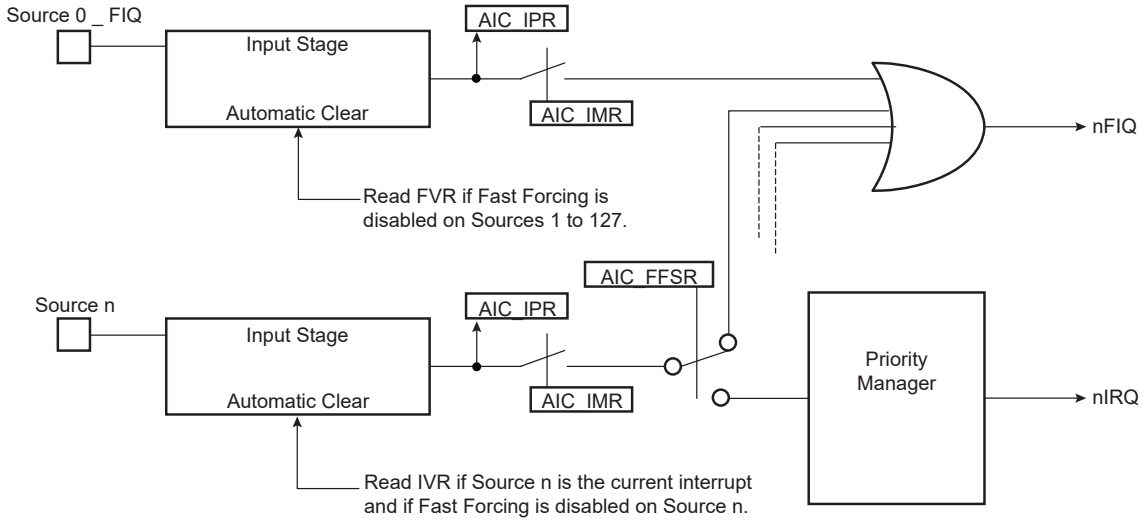
When Fast Forcing is enabled, the edge/level programming and, in certain cases, edge detection of the interrupt source is still active but the source cannot trigger a normal interrupt to the processor and is not seen by the priority handler.

If the interrupt source is programmed in Level-Sensitive mode and an active level is sampled, Fast Forcing results in the assertion of the nFIQ line to the core.

If the interrupt source is programmed in Edge-Triggered mode and an active edge is detected, Fast Forcing results in the assertion of the nFIQ line to the core.

The Fast Forcing feature does not affect the Source 0 pending bit in AIC_IPR.

© 2026 Microchip Technology Inc. and its subsidiaries



The FIQ Vector register (AIC_FVR) reads the contents of the Source Vector register (AIC_SVR), whatever the source of the fast interrupt may be. The read of the FVR does not clear Source 0 when the fast forcing feature is used and the interrupt source should be cleared by writing to AIC_ICCR.

All enabled and pending interrupt sources that have the fast forcing feature enabled and that are programmed in Edge-Triggered mode must be cleared by writing to the Interrupt Clear Command register. In doing so, they are cleared independently and thus lost interrupts are prevented.

The read of AIC_IVR does not clear the source that has the fast forcing feature enabled.

Source 0, reserved to the fast interrupt, continues operating normally and becomes one of the Fast Interrupt sources.

Figure 27.10. Fast Forcing

27.8.5. Protect Mode

The Protect mode is used to read the Interrupt Vector register without performing the associated automatic operations. This is necessary when working with a debug system. When a debugger, working either with a Debug Monitor or the Arm processor's ICE, stops the applications and updates the opened windows, it might read the AIC User Interface and thus the IVR. This has adverse consequences:

- If an enabled interrupt with a higher priority than the current one is pending, it is stacked.
- If there is no enabled pending interrupt, the spurious vector is returned.

In either case, an End of Interrupt command is necessary to acknowledge and restore the context of the AIC. This operation is generally not performed by the debug system, as the debug system would become strongly intrusive and cause the application to enter an undesired state.

This is avoided by using the Protect mode. Writing PROT in the Debug Control register (AIC_DCR) at 0x1 enables the Protect mode.

When the Protect mode is enabled, the AIC performs interrupt stacking only when a write access is performed on AIC_IVR. Therefore, the Interrupt Service Routines must write (arbitrary data) to AIC_IVR just after reading it. The new context of the AIC, including the value of AIC_ISR, is updated with the current interrupt only when AIC_IVR is written.

An AIC_IVR read on its own (e.g., by a debugger) modifies neither the AIC context nor AIC_ISR. Extra AIC_IVR reads perform the same operations. However, it is recommended to not stop the processor between the read and the write of AIC_IVR of the interrupt service routine to make sure the debugger does not modify the AIC context.

© 2026 Microchip Technology Inc. and its subsidiaries

To summarize, in normal operating mode, the read of AIC_IVR performs the following operations within the AIC:

1. Calculates active interrupt (higher than current or spurious).
2. Determines and returns the vector of the active interrupt.
3. Memorizes the interrupt.
4. Pushes the current priority level onto the internal stack.
5. Acknowledges the interrupt.

However, while the Protect mode is activated, only operations 1 to 3 are performed when AIC_IVR is read. Operations 4 and 5 are only performed by the AIC when AIC_IVR is written.

Software that has been written and debugged using the Protect mode runs correctly in normal mode without modification. However, in normal mode, the AIC_IVR write has no effect and can be removed to optimize the code.

27.8.6. Spurious Interrupt

The AIC features a protection against spurious interrupts. A spurious interrupt is defined as being the assertion of an interrupt source long enough for the AIC to assert the nIRQ, but no longer present when AIC_IVR is read. This is most prone to occur when:

- An external interrupt source is programmed in Level-Sensitive mode and an active level occurs for only a short time.
- An internal interrupt source is programmed in level-sensitive and the output signal of the corresponding embedded peripheral is activated for a short time (as is the case for the watchdog).
- An interrupt occurs just a few cycles before the software begins to mask it, thus resulting in a pulse on the interrupt source.

The AIC detects a spurious interrupt at the time AIC_IVR is read while no enabled interrupt source is pending. When this happens, the AIC returns the value stored by the programmer in the Spurious Vector register (AIC_SPU). The programmer must store the address of a spurious interrupt handler in AIC_SPU as part of the application, to enable an as fast as possible return to the normal execution flow. This handler writes in AIC_EOICR and performs a return from interrupt.

27.8.7. General Interrupt Mask

The AIC features a General Interrupt Mask bit (AIC_DCR.GMSK) to prevent interrupts from reaching the processor. Both the nIRQ and the nFIQ lines are driven to their inactive state if AIC_DCR.GMSK is set. However, this mask does not prevent waking up the processor if it has entered Idle mode. This function facilitates synchronizing the processor on a next event and, as soon as the event occurs, performs subsequent operations without having to handle an interrupt. It is strongly recommended to use this mask with caution.

27.8.8. Register Write Protection

To prevent any single software error from corrupting AIC behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the AIC Write Protection Mode Register (AIC_WPMR).

If a write access to a write-protected register is detected, the WPVS flag in the AIC Write Protection Status Register (AIC_WPSR) is set and the field WPVSRC indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading AIC_WPSR.

The following registers can be write-protected:

Reset		0	0	0	0	0	0	0

Bits 6:0 – INTSEL[6:0] Interrupt Line Selection
0–60 = Selects the interrupt line to handle.
See the section Interrupt Source Mode.

© 2026 Microchip Technology Inc. and its subsidiaries

27.9.2. AIC Source Mode Register

Name: AIC_SMR
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the AIC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Access								
Reset								

Bit	7	6	5	4	3	2	1	0
		SRCTYPE[1:0]				PRIOR[2:0]		
Access		R/W	R/W			R/W	R/W	R/W
Reset		0	0			0	0	0

Bits 6:5 – SRCTYPE[1:0] Interrupt Source Type
The active level or edge is not programmable for the internal interrupt source selected by INTSEL.

Value	Name	Description
0	INT_LEVEL_SENSITIVE	High-level sensitive for internal source. Low-level sensitive for external source.
1	EXT_NEGATIVE_EDGE	Negative-edge triggered for external source.
2	EXT_HIGH_LEVEL	High-level sensitive for internal source. High-level sensitive for external source.
3	EXT_POSITIVE_EDGE	Positive-edge triggered for external source.

Bits 2:0 – PRIOR[2:0] Priority Level
Programs the priority level of the source selected by INTSEL except FIQ source (source 0).
The priority level can be between 0 (lowest) and 7 (highest).
The priority level is not used for the FIQ.

© 2026 Microchip Technology Inc. and its subsidiaries

27.9.3. AIC Source Vector Register

Name: AIC_SVR
Offset: 0x08
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the AIC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	VECTOR[31:24]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	VECTOR[23:16]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	VECTOR[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Reset	0	0	0	0	0	0	0	0

Bits 31:0 – VECTOR[31:0] Source Vector
The user may store in this register the address of the corresponding handler for the interrupt source selected by INTSEL.

© 2026 Microchip Technology Inc. and its subsidiaries

27.9.4. AIC Interrupt Vector Register

Name: AIC_IVR
Offset: 0x10
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	IRQV[31:24]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	IRQV[23:16]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	IRQV[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	IRQV[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – IRQV[31:0] Interrupt Vector Register
Contains the vector programmed by the user in AIC_SVR or the interrupt index corresponding to the current interrupt. (See the sections AIC_SVRRER, AIC_SVRRDR and AIX_SVRRSR.)
AIC_SVR is indexed using the current interrupt number when AIC_IVR is read.
When there is no current interrupt, AIC_IVR reads the value stored in AIC_SPU.

© 2026 Microchip Technology Inc. and its subsidiaries

27.9.5. AIC FIQ Vector Register

Name: AIC_FVR
Offset: 0x14
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	FIQV[31:24]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

	PID15	PID14	PID13	PID12	PID11	PID10	PID9	PID8
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	PID7	PID6	PID5	PID4	PID3	PID2	SYS	FIQ
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31 – PIDx Interrupt Pending

PID2...PID31 refer to the identifiers as defined in the Peripheral Identifiers section.

Value	Description
0	The corresponding interrupt is not pending.
1	The corresponding interrupt is pending.

Bit 1 – SYS Interrupt Pending

Value	Description
0	The corresponding interrupt is not pending.
1	The corresponding interrupt is pending.

Bit 0 – FIQ Interrupt Pending

Value	Description
0	The corresponding interrupt is not pending.
1	The corresponding interrupt is pending.

28. Boot Sequence Controller (BSC)

28.1. Description

The System Controller embeds a Boot Sequence Controller (BSC). The boot sequence is programmable through the Boot Sequence Controller Configuration register (BSC_CR).

The BSC_CR is powered by VDDBU. Any modification of the register value is stored and applied after the next reset. The register defaults to the factory value in case of battery removal.

The BSC_CR is programmable with user programs or SAM-BA and is key-protected.

28.2. Embedded Characteristics

- Boot Sequence Settings
- VDDBU-powered Register

28.3. Product Dependencies

Refer to the “Boot Strategies” section.

© 2026 Microchip Technology Inc. and its subsidiaries

28.4. Register Summary

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0

Value	Name	Description
0x6683	PASSWD	Writing any other value in this field aborts the write operation of the BOOT field. Always reads as 0.

Bits 2:0 – BOOT[2:0] Boot Media Sequence
This value is defined in the “Boot Strategies” section. It is only written if WPKEY carries the valid value.

© 2026 Microchip Technology Inc. and its subsidiaries

29. General Purpose Backup Registers (GPBR)

29.1. Description

The System Controller embeds 256 bits of General Purpose Backup registers organized as 8 32-bit registers.

It is possible to generate an immediate clear of the content of General Purpose Backup registers 0 to 3 if a tamper event is detected on WKUP1 to WKUP8 pins. These pins are internally routed through the VDDCORE area, thus tamper events can be generated only when the VDDCORE is powered. These pins are also used for fast wake-up in Power Management Controller (PMC). Thus, if some WKUP pins are not enabled for fast wake-up in PMC, they can be enabled for tamper event detection. The immediate clear of the GPBR is enabled if RSTC_MR.ENGCLR=1.

The immediate clear on tamper detection can be extended to all General Purpose Backup registers by writing to '1' GPBR_FCLR.FCLR.

If an event has been detected on WKUP pins enabled for event detection in RTC, it is not possible to write to the General Purpose Backup registers (SYS_GPBRx) while the event has not been cleared.

SYS_GPBR0 to SYS_GPBR7 can be individually (each 32-bit part-select) read- and write-protected by configuring GPBR_MR. This register is write-once, which means that once it has been configured, the read or write protection is available until the loss of VDDBU.

29.2. Embedded Characteristics

- 256 bits of General Purpose Backup Registers
- Immediate Clear on WKUP Event
- Read and Write Protection for SYS_GPBR0 to SYS_GPBR7

29.3.1. GPBR Mode Register

Name: GPBR_MR
Offset: 0x0
Reset: 0x00000000
Property: Read/Write-Once

This register is write-once. All bits are cleared at first power-up and on each loss of VDDBU.

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

29.3.2. GPBR Full Clear Register

Name: GPBR_FCLR
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Bit	7	6	5	4	3	2	1	0
								FCLR
Access								R/W
Reset								0

Bit 0 – FCLR Full Clear Enable
GPBR full clear is only possible if the system is not in Backup mode. In Backup mode, FCLR has no effect.

Value	Description
0	SYS_GPBR0 to SYS_GPBR3 are immediately cleared in case of fast wake-up pin tamper event.
1	All SYS_GPBRx are immediately cleared in case of fast wake-up pin tamper event.

© 2026 Microchip Technology Inc. and its subsidiaries

29.3.3. General Purpose Backup Register x [x=0..7]

Name: SYS_GPBRx
Offset: 0x08 + x*0x04 [x=0..7]
Reset: 0x00000000
Property: R/W

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

These registers are reset at first power-up and on each loss of VDDBU.

If an event has been detected on WKUP pins enabled for tamper event detection in the RTC, it is not possible to write to SYS_GPBRx as long as the event has not been cleared.

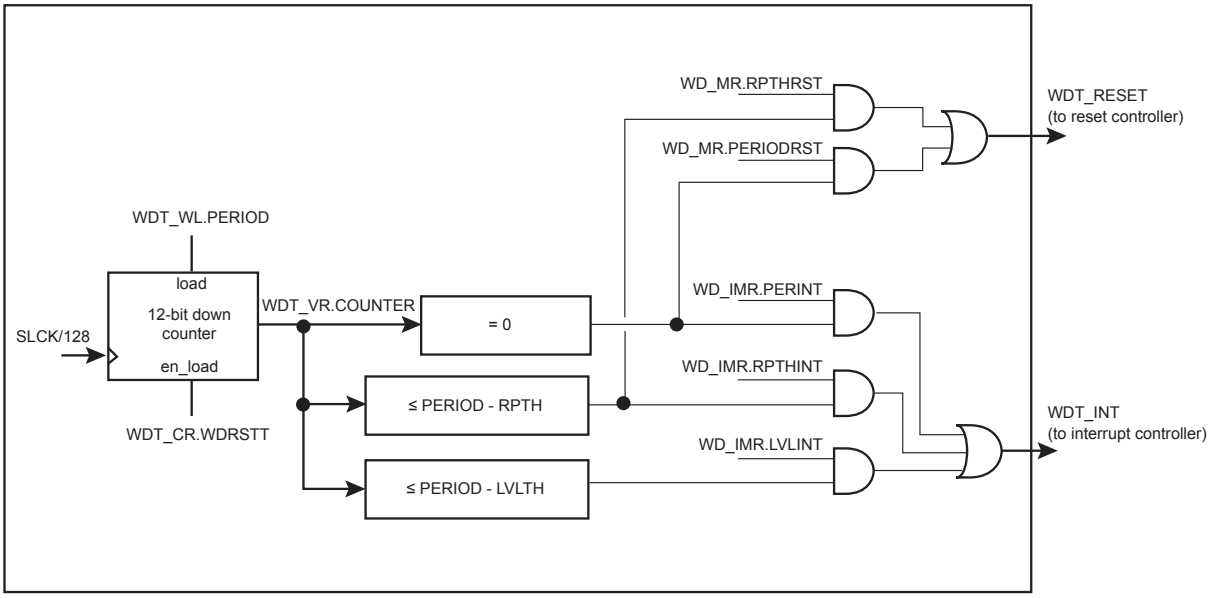
30. Watchdog Timer (WDT)

30.1. Description



The Watchdog Timer (WDT) is used to prevent system lockup if the software becomes trapped in a deadlock. It features one 12-bit down counter that allows a watchdog period of up to 16 seconds (slow clock around 32 kHz). The WDT can generate a general reset or a processor reset only. In addition, it can be stopped while the processor is in Debug mode or Sleep mode (Idle mode).

30.2. Embedded Characteristics

- 12-bit Key-protected Programmable Counter
- Watchdog Clock is Independent from Processor Clock
- Provides Reset or Interrupt Signals to the System
- Counter May Be Stopped while the Processor is in Debug State or in Idle Mode

30.3. Block Diagram

Figure 30.1. WDT Block Diagram

30.4. Functional Description

The WDT is used to prevent system lockup if the software becomes trapped in a deadlock. It is supplied with VDDCORE. It restarts with initial values on processor reset.

The WDT is built around a 12-bit down counter loaded with the value defined in field PERIOD of the Window Level Register (WDT_WLR). WDT uses slow clock divided by 128 to establish the maximum watchdog period to 16 seconds (with a typical slow clock of 32.768 kHz).

The following parameters can be configured:

- Watchdog event period: a watchdog event occurs when the 12-bit down counter reaches 0, and leads to either an interrupt (if bit PERINT in the Interrupt Mask register (WDT_IMR) is high) or a reset (if bit PERIODRST in the Mode register (WDT_MR) is high).

© 2026 Microchip Technology Inc. and its subsidiaries

- Minimum restart period: if the restart command is performed before this period, WDT creates a repeat violation. A repeat violation leads to either an interrupt (if WDT_IMR.RPTHINT = 1) or a reset (if WDT_MR.RPTHRST = 1).
- Maximum period before single interrupt event: if WDT_IMR.LVLINT = 1, a single interrupt is generated (no reset). The WDT_ILR.LVLTH value must be lower than WDT_WLR.PERIOD.

After a processor reset, the value of PERIOD is 0xFFF, corresponding to the maximum value of the counter with the external reset generation enabled (bit PERIODRST at 1 after a backup reset). This means that the WDT is running at reset, i.e., at powerup. The user can either disable the WDT by setting bit WDT_MR.WDDIS to '1' or reprogram the WDT to meet the maximum WDT period the application requires.

If the WDT is restarted by writing into the corresponding Control register (WDT_CR), the corresponding WDT_MR must not be programmed during a period of time of three slow clock periods following the WDT_CR write access. In any case, programming a new value in WDT_MR automatically initiates a restart instruction.

WDT_MR, WDT_WLR and WDT_ILR (Interrupt Level register) can be written until a WDT_CR.LOCKMR command is issued in the corresponding WDT_CR. Only a peripheral reset can configure the bit LOCKMR to 0.

When the bit WDT_CR.LOCKMR = 0, writing WDT_WLR reloads the corresponding WDT with the newly programmed mode parameters.

In normal operation, the user reloads the WDT at regular intervals before the timer underflow occurs, by setting bit WDT_CR.WDRSTT. The WDT counter is then immediately reloaded from PERIOD and restarted, and the slow clock 128 divider is reset and restarted.

Writing WDR_CR without the correct hard-coded key has no effect (see Watchdog Timer Control Register).

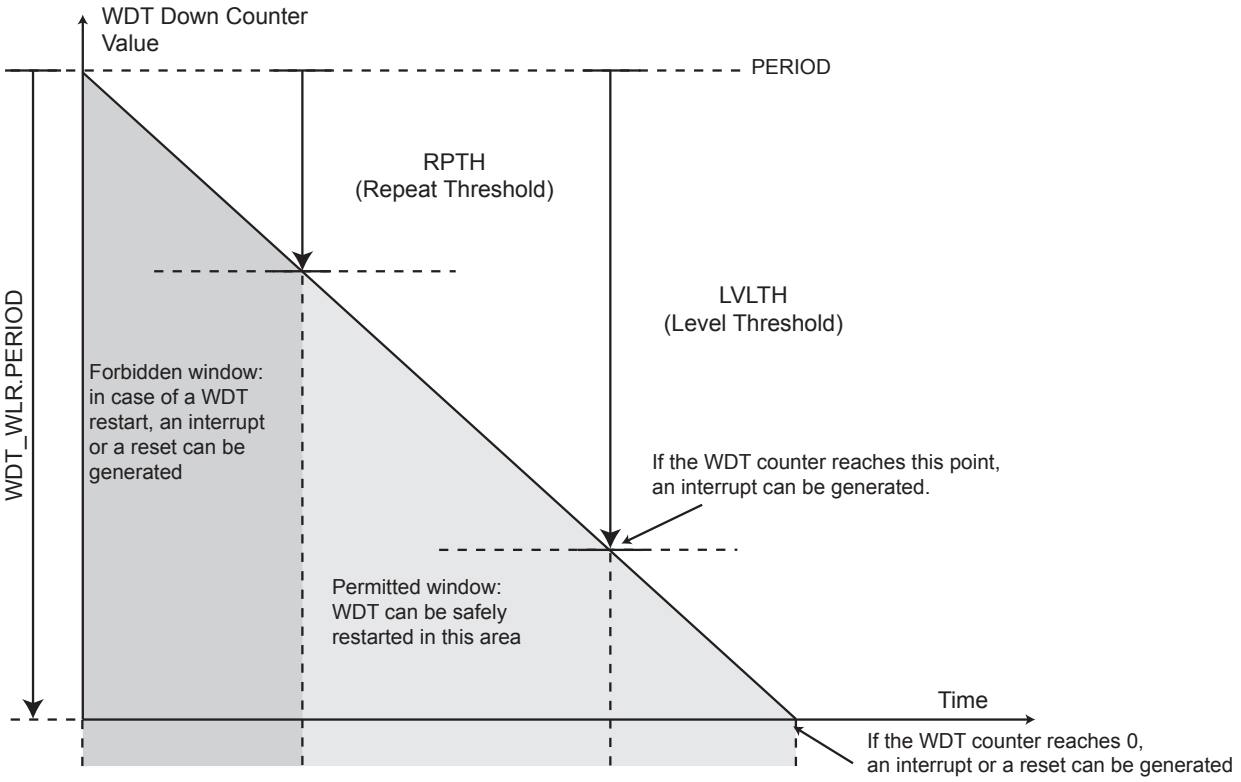
A repeat threshold can be defined for each watchdog in order to protect against dead-locks that would repeatedly restart the watchdog. WDT_WLR.RPTH defines the minimum number of cycles to wait after a watchdog restart before the WDT can be started again. If a watchdog restart occurs before this limit is reached, a repeat threshold failure is asserted and the RPTHINT bit in the Interrupt Status register (WDT_ISR) is set to one.

If WDT_IMR.RPTHINT is high and a repeat threshold violation occurs in the WDT, an interrupt is generated.

If WDT_MR.RPTHRST is high and a repeat threshold violation occurs in the WDT, a watchdog reset is generated.

WDT reload must occur while the WDT counter is within a window between 0 and (PERIOD–RPTH). PERIOD and RPTH are defined in WDT_WLR.

Note that this feature can be disabled by programming a null RPTH value. In such configuration, restarting the WDT is permitted in the whole range [0 up to PERIOD] and does not generate an error. This is the default configuration on reset (RPTH is null).



If a reset is generated or if WDT_SR is read, the status bits are reset and the interrupt is cleared.

Writing WDT_MR reloads and restarts the down counter.

While the processor is in debug state or in Sleep mode, the counter may be stopped depending on the value programmed for the bits WDIDLEHLT and WDDBGHLT in WDT_MR.

30.5.1. Watchdog Timer Control Register

Name: WDT_CR
Offset: 0x00
Reset: –
Property: Write-only

The WDT_CR register values must not be modified within three slow clock periods following a restart of the WDT performed by a write access in WDT_CR. Any modification will cause the WDT to trigger an end of period earlier than expected.

Bit	31	30	29	28	27	26	25	24

Bits 31:24 – KEY[7:0] Password

Value	Name	Description
0xA5	PASSWD	Writing any other value in this field aborts the write operation.

Bit 4 – LOCKMR Lock Mode Register Write Access

Value	Description
0	No effect.
1	Locks the configuration registers if KEY is written to 0xA5. Write accesses to WDT_MR, WDT_WLR and WDT_ILR have no effect.

Bit 0 – WDRSTT Watchdog Restart

Value	Description
0	No effect.
1	Restarts the WDT if KEY is written to 0xA5.

© 2026 Microchip Technology Inc. and its subsidiaries

30.5.2. Watchdog Timer Mode Register

Name: WDT_MR
Offset: 0x04
Reset: 0x00000030
Property: Read/Write

Write access to this register has no effect if the LOCKMR command is issued in WDT_CR (unlocked on hardware reset).

The WDT_MR register values must not be modified within three slow clock periods following a restart of the WDT performed by a write access in WDT_CR. Any modification will cause the WDT to trigger an end of period earlier than expected.

Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
	COUNTER[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 11:0 – COUNTER[11:0] Watchdog Down Counter Value

Shows the current value of the WDT down counter for debug operation.
Due to the asynchronous operation of the WDT with respect to the rest of the chip, to be certain that the value read in this register is valid and stable, it is necessary to read the register twice. If the data is the same both times, then it is valid. Therefore, a minimum of two and a maximum of three accesses are required.

© 2026 Microchip Technology Inc. and its subsidiaries

30.5.4. Watchdog Timer Window Level Register

Name: WDT_WLR
Offset: 0x0C
Reset: 0x00000FFF
Property: Read/Write

Bit	31	30	29	28	27	26	25	24

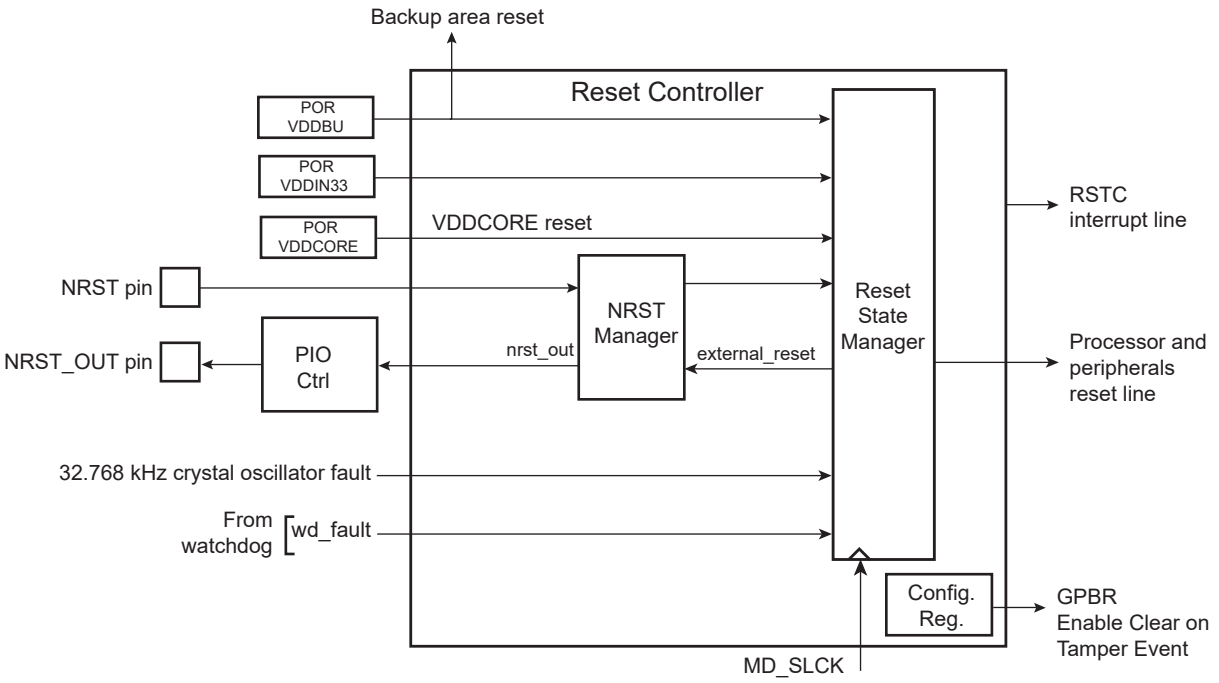
31. Reset Controller (RSTC)

31.1. Description

The Reset Controller (RSTC) handles all the resets of the system without any external components. It reports which reset occurred last.

The RSTC is driven by Power-on Reset (POR) cells, software, an external reset pin, and peripheral events.



The RSTC drives simultaneously the External reset and the Peripheral and Processor resets.

31.2. Embedded Characteristics

- Driven by Embedded Power-on Reset, Software, External Reset Pin and Peripheral Events
- Management of All System Resets, Including
  - External devices through an I/O multiplexed output reset pin
  - Processor
  - Peripheral set
- Reset Source Status
  - Status of the last reset
  - Either VDDCORE, VDDIN33 and VDDBU POR reset, Software reset, User reset, Watchdog reset, 32.768 kHz Crystal Oscillator Failure Detection reset

31.3. Block Diagram

Figure 31.1. RSTC Block Diagram

© 2026 Microchip Technology Inc. and its subsidiaries

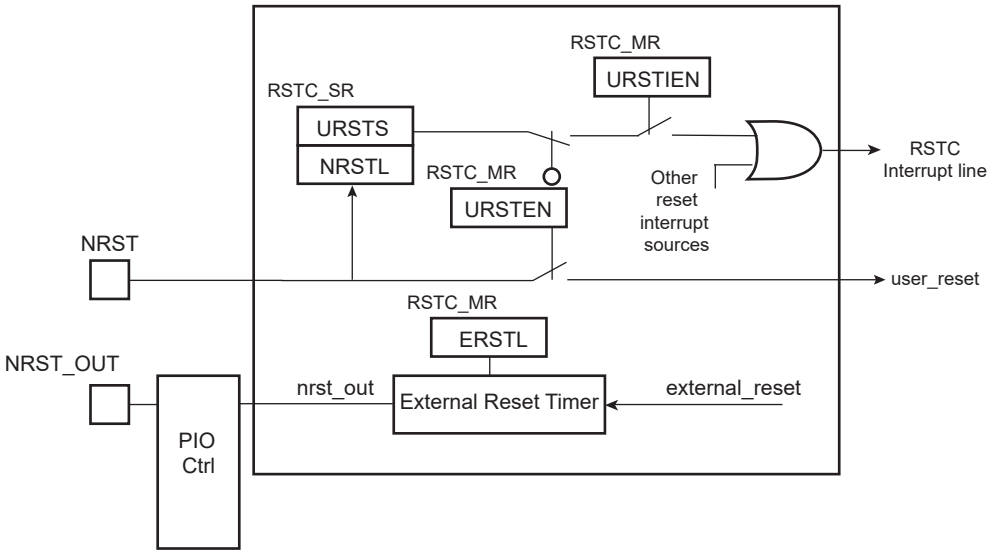
31.4. Functional Description

The RSTC is made up of an NRST manager and a reset state manager. The RSTC clock is MD_SLCK (monitoring domain slow clock). The RSTC generates the following reset signals:

- Processor reset line (also resets the Watchdog Timer)
- Entire set of embedded peripherals reset line
- NRST_OUT pin

Note: Processor and peripheral reset lines are driven in the same way.

These internal reset signals are asserted by the RSTC, either on events generated by peripherals, events on NRST pin, or on software action. The reset state manager controls the generation of reset signals and drives the NRST_OUT pin when required.



The NRST manager asserts the NRST_OUT pin during a programmable time, thus controlling external device resets.

The Mode register (RSTC_MR), used to configure the RSTC, is powered by VDDBU.

31.4.1. NRST Manager

The NRST manager samples the NRST pin and drives the NRST_OUT pin low when required by the reset state manager. See the following figure.

Figure 31.2. NRST Pin Management

31.4.1.1. NRST Signal or Interrupt

The NRST manager handles the NRST input line asynchronously if RSTC_MR.URSTASYNC =1. When the NRST input is low, a user reset is immediately reported to the Reset State manager and the internal reset signals are asserted even if there is a clock failure on MD_SLCK (safe reset).

The NRST manager handles the NRST input line synchronously if RSTC_MR.URSTASYNC=0. When the line is low, it is first resynchronized on slow clock before it is reported to the Reset State manager. In both cases, when the NRST goes from low to high, the internal reset is synchronized with the monitoring slow clock to provide a safe internal de-assertion of reset (if enabled).

If RSTC_MR.URSTEN=0, the assertion of the NRST input pin does not trigger a VDDCORE domain reset.

The level of the pin NRST is reported in NRSTL of the Status register (RSTC_SR).

As soon as the pin NRST is asserted (low level), RSTC_SR.URSTS=1. This bit is cleared on read.

© 2026 Microchip Technology Inc. and its subsidiaries

If RSTC_MR.URSTIEN=1, the assertion of NRST pin triggers an interrupt rather than a VDDCORE reset.

31.4.1.2. NRST_OUT External Reset Control

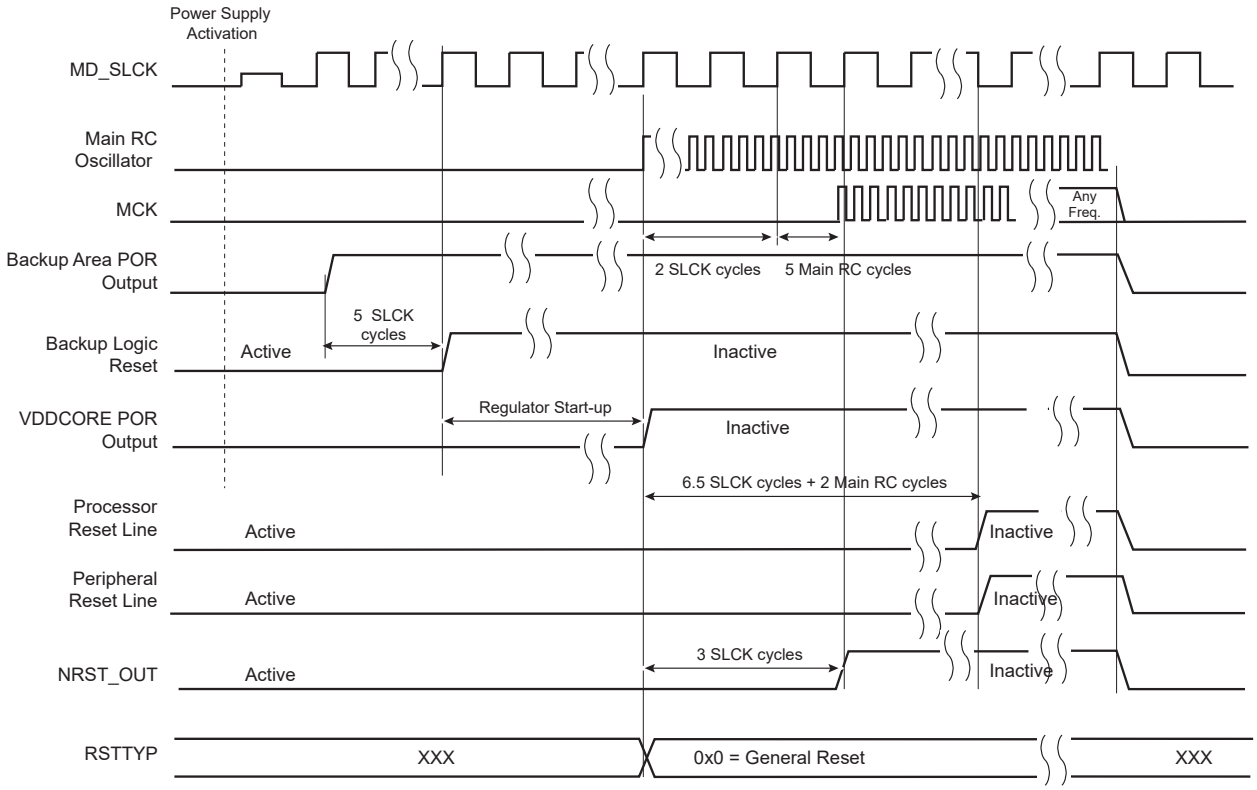
The RSTC can be configured to assert the external reset line (NRST_OUT). The NRST_OUT pin is driven low for a time programmed by RSTC_MR.ERSTL. This assertion duration lasts $2^{(ERSTL+1)}$ MD_SLCK cycles. This assertion duration time is in the range of 60 µs to 2 seconds. If ERSTL=0, a two slow clock period duration is generated on the NRST_OUT pin.

This feature allows the NRST_OUT line to be compliant with any external devices connected on the system reset (i.e., when external devices require a longer start-up time than the processor system).

31.4.2. Reset States

The reset state manager handles the different reset sources and generates the internal reset signals. It reports the reset status in RSTC_SR.RSTTYP. RSTC_SR.RSTTYP is updated when the Processor reset is released.

If more than one reset event occurred since the last read of RST_SR, the field RSTTYP reports the first reset that occurred.



31.4.2.1. General Reset

A general reset occurs when a VDDBU Power-on reset is detected. The internal VDDCORE reset signal is asserted when a general reset occurs. All the reset signals are released and RSTC_SR.RSTTYP reports a general reset.

The NRST_OUT line rises two cycles after the VDDCORE reset line, as ERSTL defaults at value 0x0.

The following figure shows how the general reset affects the reset signals.

Figure 31.3. General Reset Timing Diagram

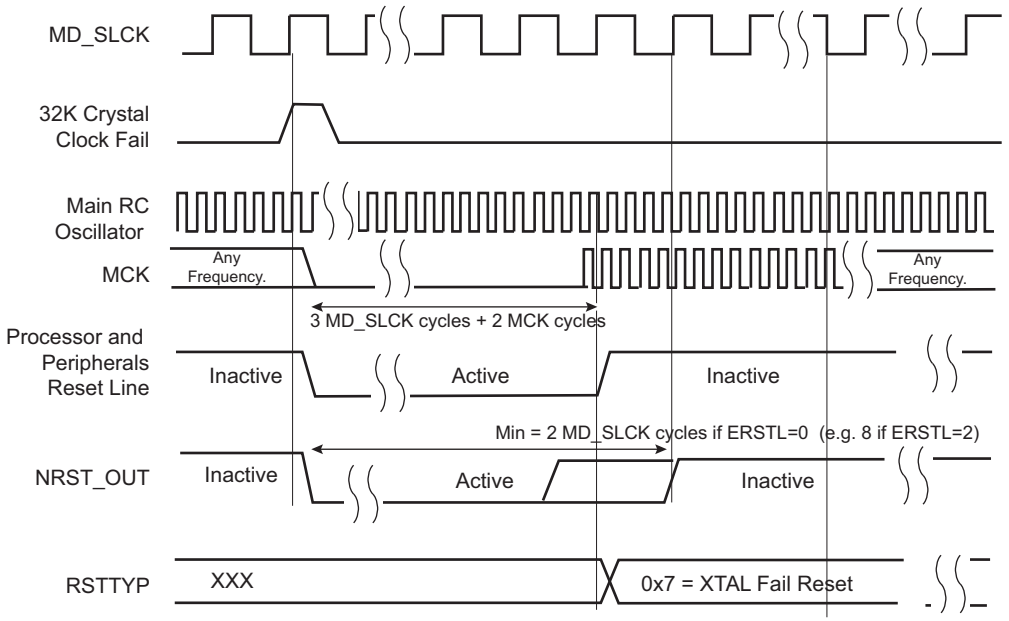
© 2026 Microchip Technology Inc. and its subsidiaries

31.4.2.2.Backup Exit Reset

A Backup reset occurs when the chip exits from Backup mode. While exiting Backup mode, the VDDCORE reset signal is de-asserted.

RSTC_SR.RSTTYP is updated to report a Backup reset.

31.4.2.3.32.768 kHz Crystal Oscillator Failure Detection Reset



The 32.768 kHz Crystal Oscillator Failure Detection reset is done when the 32.768 kHz crystal oscillator frequency monitoring circuitry in the PMC detects a failure and RSTC_MR.SCKSW is written to '1'. This reset lasts three slow clock cycles.

When RSTC_MR.SCKSW is written to ‘0’, the 32.768 kHz crystal oscillator fault has no impact on the RSTC.

During the 32.768 kHz Crystal Oscillator Failure Detection reset, the Processor reset and the Peripheral reset are asserted. The NRST_OUT line is also asserted, depending on the value of RSTC_MR.ERSTL.

When the 32.768 kHz crystal oscillator failure generates a VDDCORE reset, PMC_SR.XT32KERR is automatically cleared by the Peripheral and Processor resets.

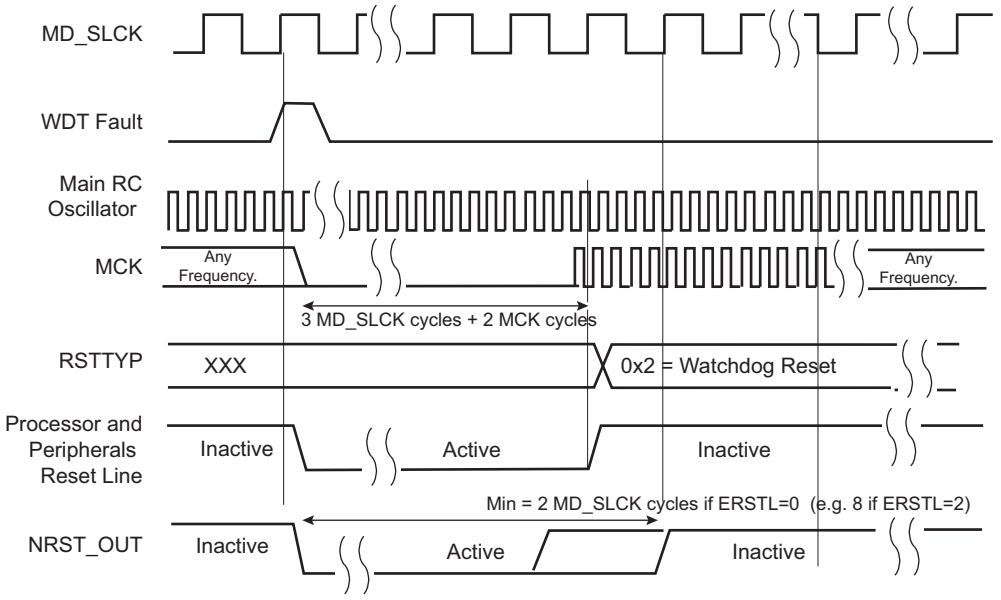
Figure 31.4. 32.768 kHz Crystal Oscillator Failure Detection Reset Timing Diagram

31.4.2.4.Watchdog Reset

The Watchdog reset is entered when a watchdog fault occurs. This reset lasts three MD_SLCK cycles.

When in Watchdog reset, the Processor reset and the Peripheral reset are asserted. The NRST_OUT line is also asserted, depending on the value of RSTC_MR.ERSTL. However, the resulting low level on NRST_OUT does not result in a User reset state.

The WDT is reset by the Processor reset signal. As the watchdog fault always causes a Processor reset if WDT_MR.WDRSTEN is written to ‘1’, the WDT is always reset after a Watchdog reset, and the Watchdog is enabled by default and with a period set to a maximum.



When WDT_MR.WDRSTEN is written to ‘0’, the watchdog fault has no impact on the RSTC.

After a watchdog overflow occurs, the report on the RSTC_SR.RSTTYP may differ (either WDT_RST or USER_RST) depending on the external components driving the NRST pin. For example, if the

© 2026 Microchip Technology Inc. and its subsidiaries

NRST line is driven through a resistor and a capacitor (NRST pin debouncer), the reported value is USER_RST if the low-to-high transition is greater than one MD_SLCK cycle.

Figure 31.5. Watchdog Reset Timing Diagram

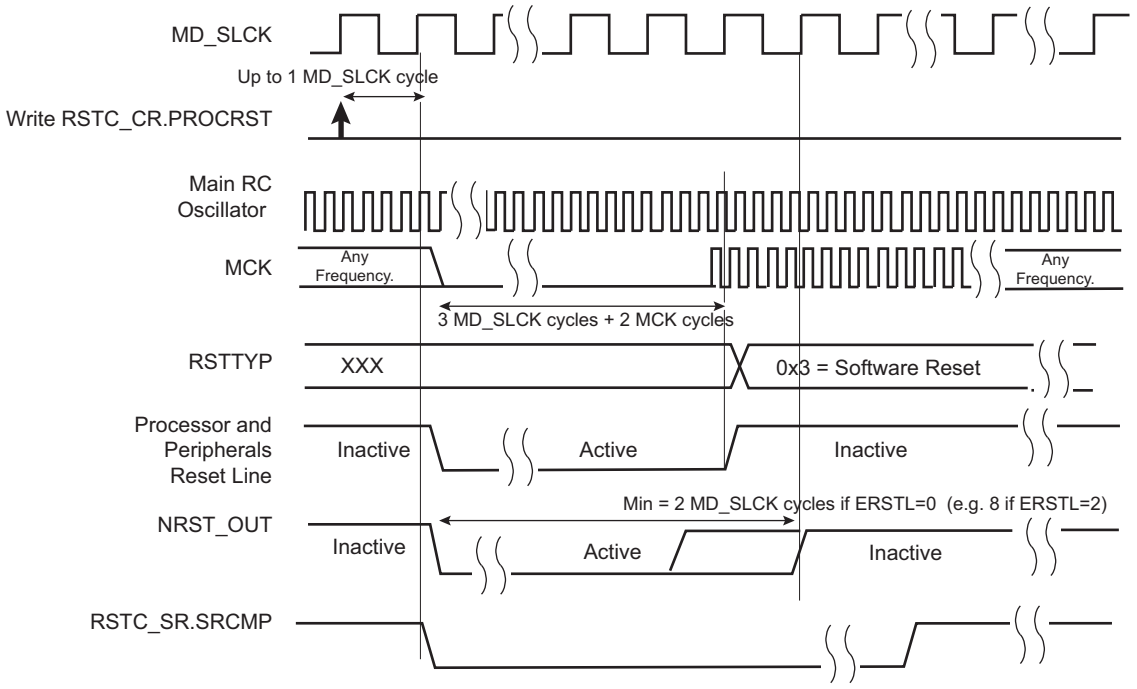
31.4.2.5.Software Reset

The RSTC offers commands to assert the different reset signals. These commands are performed by writing the Control register (RSTC_CR) with the following bits at '1':

- RSTC_CR.PROCRST: Writing a '1' to PROCRST resets the processor and all the embedded peripherals, including the memory system and, in particular, the Remap Command.
- RSTC_CR.EXTRST: Writing a '1' to EXTRST asserts low the NRST_OUT pin during a time defined by the field RSTC_MR.ERSTL.

The Software reset is entered if at least one of these bits is written to '1' by the software. All these commands can be performed independently or simultaneously. The Software reset lasts three MD_SLCK cycles.

The internal reset signals are asserted as soon as the register write is performed. They are released when the Software reset has ended, i.e., synchronously to MD_SLCK.



If EXTRST is written to '1', the NRST_OUT pin is asserted depending on the configuration of RSTC_MR.ERSTL. However, the resulting falling edge on NRST_OUT does not lead to a User reset.

If and only if the RSTC_CR.PROCRST is written to '1', the RSTC reports the software status in field RSTC_SR.RSTTYP. Other software resets are not reported in RSTTYP.

As soon as a software operation is detected, RSTC_SR.SRCMP is written to '1'. SRCMP is cleared at the end of the Software reset. No other Software reset can be performed while SRCMP='1', and writing any value in the RSTC_CR has no effect.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 31.6. Software Reset Timing Diagram (PROCRST)

31.4.2.6. User Reset

The User reset is entered when a low level is detected on the NRST pin and RSTC_MR.URSTEN =1. If URSTASYNC=1, a falling edge of the NRST input signal immediately asserts internal reset lines. If URSTASYNC=0, the NRST input signal is resynchronized and internal reset lines are asserted once a falling edge has been detected on the resynchronized NRST input signal.

The Processor reset and the Peripheral reset are asserted.

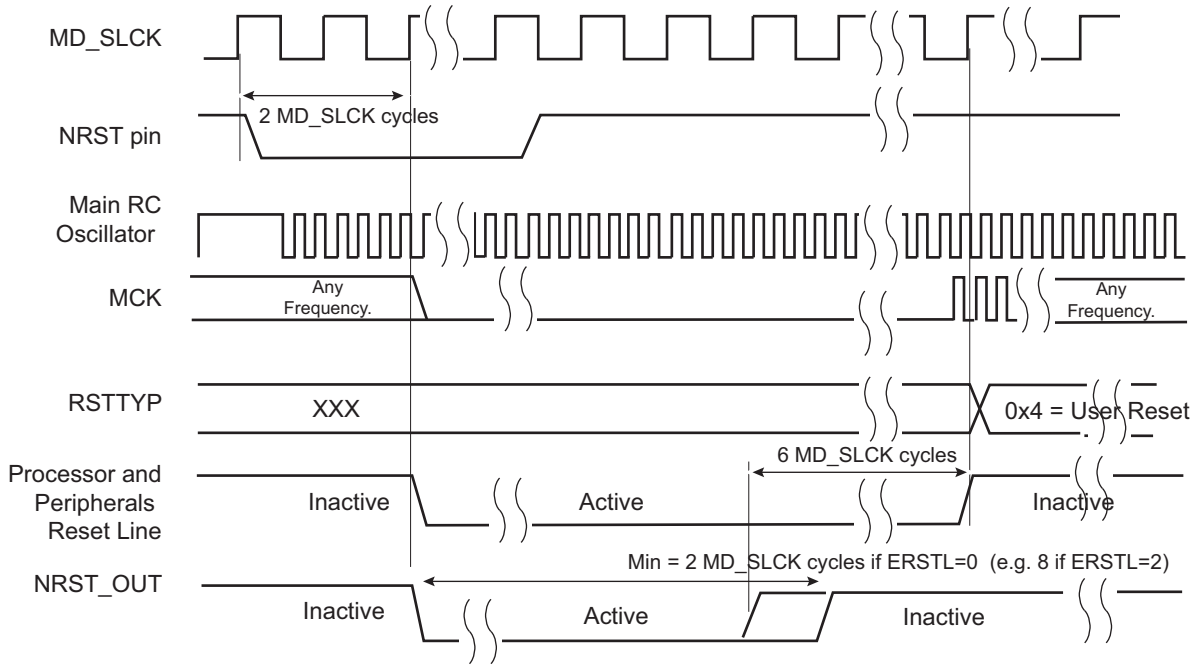
The User reset is released when NRST rises, after a two-cycle resynchronization time and a 2-cycle processor start-up. The processor clock is re-enabled as soon as NRST is confirmed high.

When the Processor reset signal is released, RSTC_SR.RSTTYP is loaded with the value 0x4, indicating a User reset.

The NRST manager ensures that the NRST_OUT line is asserted as programmed in the field ERSTL. However, if NRST is driven low externally, the internal reset lines remain asserted until NRST rises.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 31.7. User Reset State (URSTASYNC = '0')



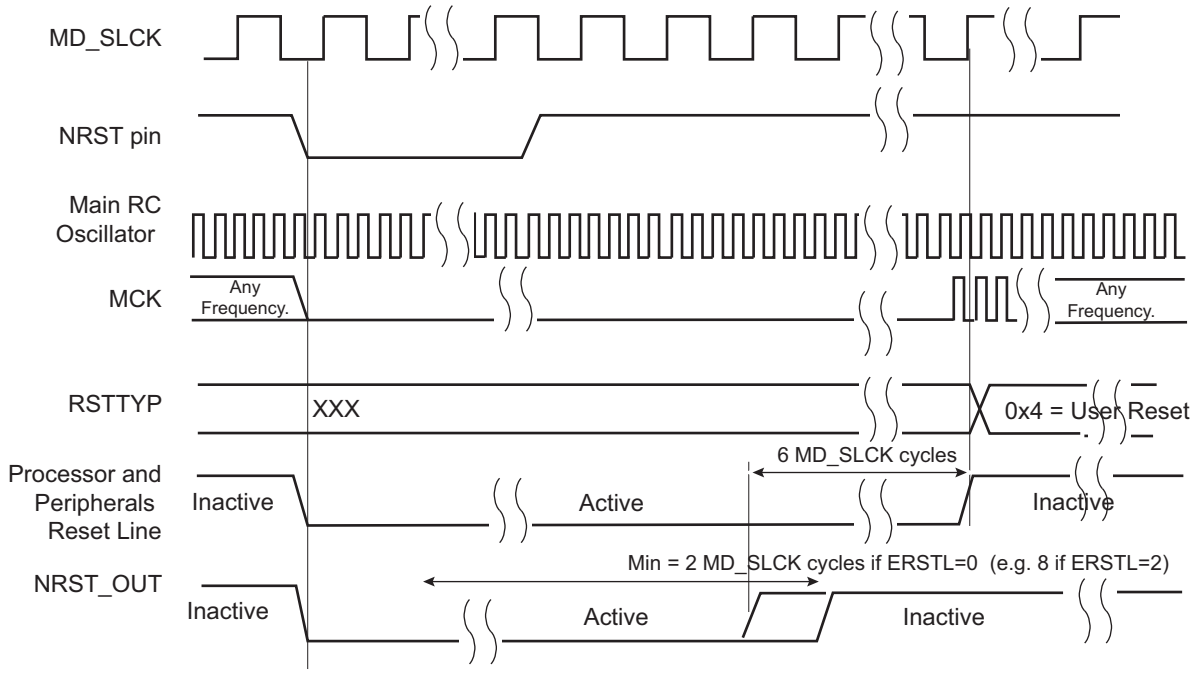


Figure 31.8. User Reset State (URSTASYNC = '1')

31.4.3. Reset State Priorities

The reset state manager manages the priorities among the different reset sources. The resets are listed in order of priority as follows:

1. General reset
2. Backup reset
3. 32.768 kHz Crystal Failure Detection reset

© 2026 Microchip Technology Inc. and its subsidiaries

4. Watchdog reset
5. Software reset
6. User reset

Specific cases are listed below:

- When in User reset:
  - A watchdog event is impossible because the WDT is being reset by the Processor reset signal.
  - A Software reset is impossible, since the Processor reset is being activated.
- When in Software reset:
  - A watchdog event has priority over the current state.
  - The NRST has no effect.
- When in Watchdog reset:
  - The Processor reset is active and so a Software reset cannot be programmed.
  - A User reset cannot be entered.

31.5.1. RSTC Control Register

Name: RSTC_CR
Offset: 0x00
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
	KEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
					EXTRST			PROCRST
Access					W			W
Reset					–			–

Bits 31:24 – KEY[7:0] System Reset Key

Value	Name	Description
0xA5	PASSWD	Writing any other value in this field aborts the write operation.

Bit 3 – EXTRST External Reset

Value	Description
0	No effect.
1	If KEY = 0xA5, asserts the NRST_OUT pin.

Bit 0 – PROCRST Processor Reset

Value	Description
0	No effect.
1	If KEY = 0xA5, resets the processor and all the embedded peripherals.

© 2026 Microchip Technology Inc. and its subsidiaries

31.5.2. RSTC Status Register

Name: RSTC_SR
Offset: 0x04
Reset: 0x00000001
Property: Read-only

The reset value assumes that a general reset has been performed, subject to change if other types of reset are generated.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access							R	R
Reset							0	0

Bit	15	14	13	12	11	10	9	8
Access						R	R	R
Reset						0	0	0

Bit	7	6	5	4	3	2	1	0
Access								R
Reset								1

Bit 17 – SRCMP Software Reset Command in Progress
When set, indicates that a software reset command is in progress and that no further software reset should be performed until the end of the current one. This bit is automatically cleared at the end of the current software reset.

Value	Description
0	No software command is being performed by the RSTC. The RSTC is ready for a software command.
1	A software reset command is being performed by the RSTC. The RSTC is busy.

Bit 16 – NRSTL NRST Pin Level
Registers the NRST pin level sampled on each MCK rising edge.

Bits 10:8 – RSTTYP[2:0] Reset Type
Reports the cause of the last processor reset. Reading RSTC_SR does not reset this field.

Value	Name	Description
0	GENERAL_RST	First power-up reset
1	BACKUP_RST	Return from Backup mode
2	WDT_RST	Watchdog fault occurred
3	SOFT_RST	Processor reset required by the software
4	USER_RST	NRST pin detected low
5	–	Reserved
6	–	Reserved
7	SLCK_XTAL_RST	32.768 kHz crystal failure detection fault occurred

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 0 – URSTS User Reset Status

A high-to-low transition of the NRST pin sets URSTS. This transition is also detected on the MCK rising edge. If the user reset is disabled (RSTC_MR.URSTEN = 0) and if the interrupt is enabled by RSTC_MR.URSTIEN, URSTS triggers an interrupt. Reading RSTC_SR resets URSTS and clears the interrupt.

Value	Description
0	No high-to-low edge on NRST happened since the last read of RSTC_SR.
1	At least one high-to-low transition of NRST has been detected since the last read of RSTC_SR.

© 2026 Microchip Technology Inc. and its subsidiaries

31.5.3. RSTC Mode Register

Name: RSTC_MR
Offset: 0x08
Reset: 0x00000001
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode Register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
	KEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	0	0	0	0

Bit	23	22	21	20	19	18	17	16
				ENGCLR				
Access				R/W				
Reset				0				

Bit	15	14	13	12	11	10	9	8
					ERSTL[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
				URSTIEN		URSTASYNC	SCKSW	URSTEN
Access				R/W		R/W	R/W	R/W
Reset				0		0	0	1

Bits 31:24 – KEY[7:0] Write Access Password

Value	Name	Description
0xA5	PASSWD	Writing any other value in this field aborts the write operation. Always reads as 0.

Bit 20 – ENGCLR Enable GPBR Clear on Tamper Event

Value	Description
0	Disables the GPBR immediate clear on tamper detection event.
1	Enables the GPBR immediate clear on tamper detection event

Bits 11:8 – ERSTL[3:0] External Reset Length

This field defines the external reset length. The external reset pin RST_OUT is asserted during a time of $2^{(ERSTL+1)}$ MD_SLCK cycles. This allows assertion duration to be programmed between 60 µs and 2 seconds. Note that synchronization cycles must also be considered when calculating the actual reset length as previously described.

Bit 4 – URSTIEN User Reset Interrupt Enable

Value	Description
0	RSTC_SR.URSTS at ‘1’ has no effect on the RSTC interrupt line.
1	RSTC_SR.URSTS at ‘1’ asserts the RSTC interrupt line if URSTEN = 0.

Bit 2 – URSTASYNC User Reset Asynchronous Control

See NRST Signal or Interrupt for important information on the use of URSTASYNC.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	The NRST input signal is managed synchronously.
1	The NRST input signal is managed asynchronously. **Note:** This mode cannot be selected if the external bus interface drives an SDR/DDR memory device and another memory on the same bus.

Bit 1 – SCKSW Slow Clock Switching

Value	Description
0	The detection of a 32.768 kHz crystal failure has no effect.
1	The detection of a 32.768 kHz crystal failure resets the logic supplied by VDDCORE.

Bit 0 – URSTEN User Reset Enable

Value	Description
0	The detection of a low level on the NRST pin does not generate a user reset.
1	The detection of a low level on the NRST pin triggers a user reset.

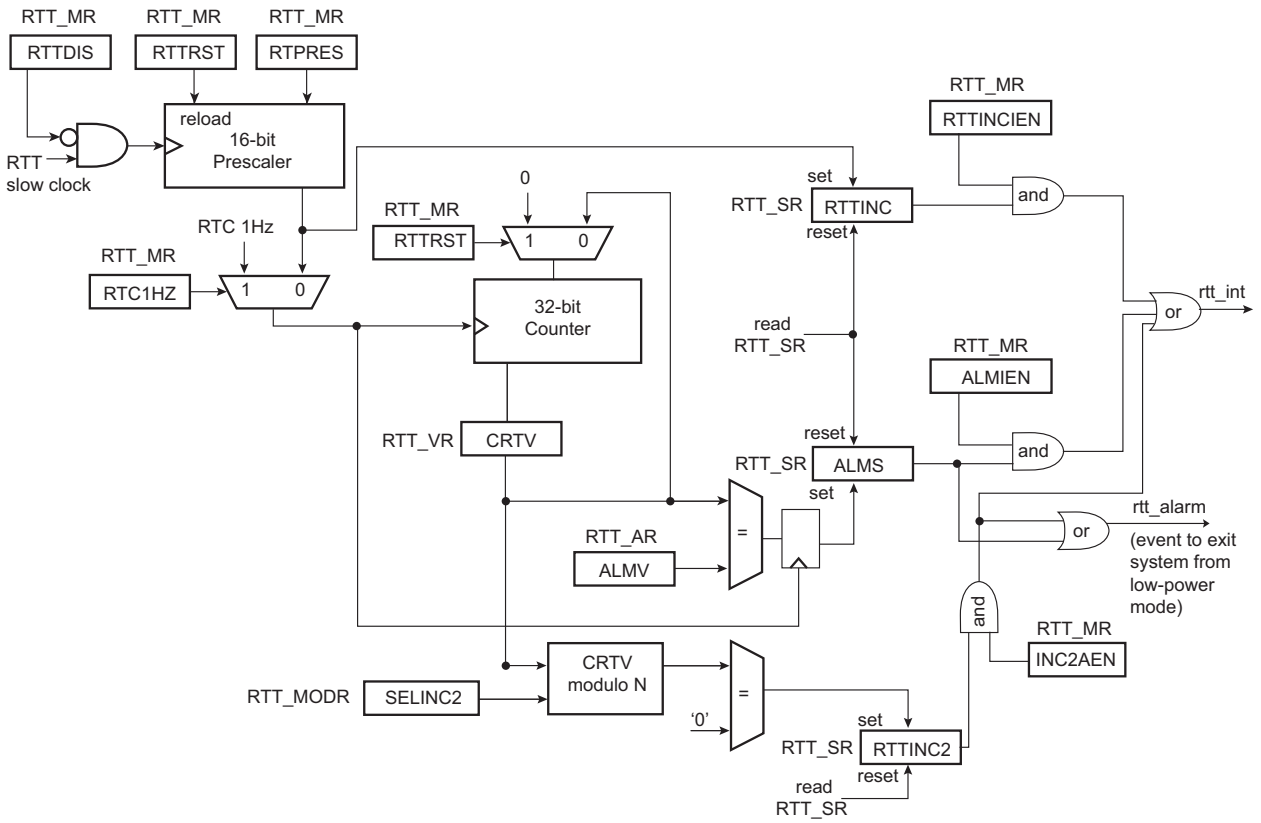
© 2026 Microchip Technology Inc. and its subsidiaries

32. Real-Time Timer (RTT)

32.1. Description

The Real-Time Timer (RTT) is built around a 32-bit counter used to count roll-over events of the programmable 16-bit prescaler driven from the 32-kHz slow clock source. It generates a periodic interrupt and/or triggers an alarm on a programmed value.

The RTT can also be configured to be driven by the 1Hz RTC signal, thus taking advantage of a calibrated 1Hz clock.



The slow clock source can be fully disabled to reduce power consumption when only an elapsed seconds count is required.

32.2. Embedded Characteristics

- 32-bit Free-running Counter on Prescaled Slow Clock or RTC Calibrated 1Hz Clock
- 16-bit Configurable Prescaler
- Interrupt on Alarm or Counter Increment
- Programmable Event

32.3. Block Diagram

Figure 32.1. RTT Block Diagram

32.4. Functional Description

The programmable 16-bit prescaler value can be configured through the RTPRES field in the RTT Mode register (RTT_MR).

© 2026 Microchip Technology Inc. and its subsidiaries

Configuring RTPRES to 0x8000 (default value) corresponds to feeding the real-time counter with a 1Hz signal (if the slow clock is 32.768 kHz). The 32-bit counter can count up to 2^{32} seconds, corresponding to more than 136 years, then roll over to 0. Bit RTTINC in the RTT Status register (RTT_SR) is set each time there is a prescaler roll-over (see the figure below).

The real-time 32-bit counter can also be supplied by the 1Hz RTC clock. This mode is applicable when the RTC 1Hz is calibrated (RTC_MR.CORRECTION ≠ 0) in order to ensure the synchronism between RTC and RTT counters.

Setting RTT_MR.RTC1HZ drives the 32-bit RTT counter from the 1Hz RTC clock. In this mode, RTPRES has no effect on the 32-bit counter.

The prescaler roll-over generates an increment of the RTT counter if RTC1HZ = 0. Otherwise, if RTC1HZ = 1, the RTT counter is incremented every second. RTTINC is set independently from the 32-bit counter increment.

The RTT can also be used as a free-running timer with a lower time-base. The best accuracy is achieved by writing RTT_MR.RTPRES to 3.

Programming RTPRES to 1 or 2 is forbidden.

The CRTV field can be read at any time in the RTT Value register (RTT_VR). As this value can be updated asynchronously with the peripheral bus clock, CRTV must be read twice at the same value to read a correct value.

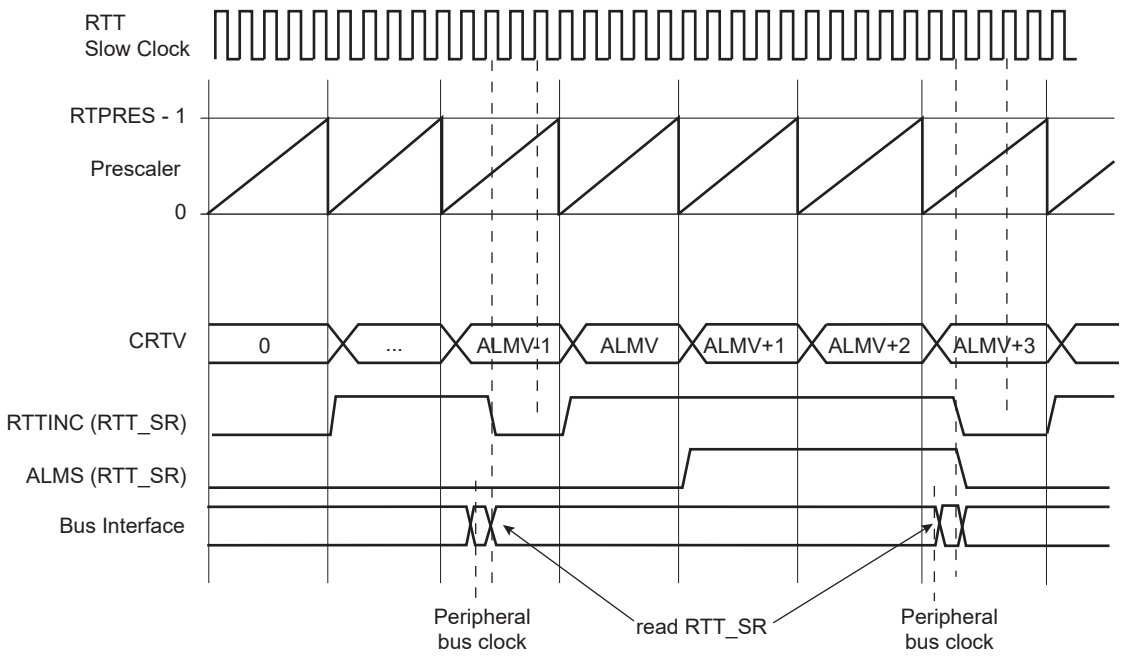
The current value of the counter is compared with the value written in the RTT Alarm register (RTT_AR). If the counter value matches the alarm, the ALMS bit in the RTT_SR is set. The RTT_AR is set to its maximum value (0xFFFFFFFF) after a reset.

ALMS is always a source of the RTT alarm signal that may be used to exit the system from low power modes (see the RTT Block Diagram above).

The alarm interrupt must be disabled (RTT_MR.ALMIEN must be cleared) when writing a new value to RTT_AR.ALMV.

RTT_SR.RTTINC can be used to start a periodic interrupt. The period is one second when RTT_MR.RTPRES = 0x8000 and the slow clock = 32.768 kHz.

RTT_MR.RTTINCIEN must be cleared prior to writing a new value in RTT_MR. RTPRES.



Reading RTT_SR automatically clears RTT_SR.RTTINC and RTT_SR.ALMS.

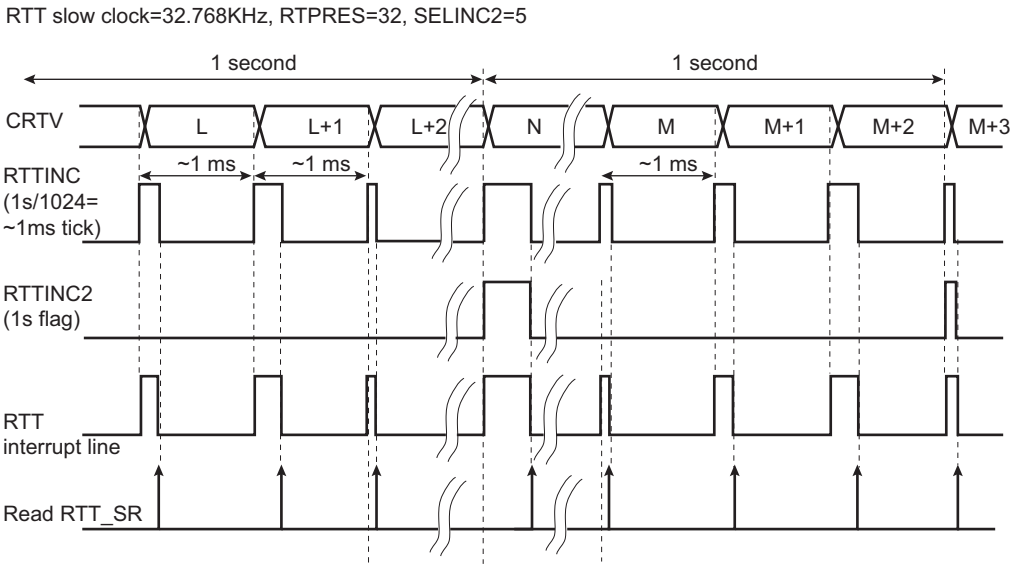
Writing RTT_MR.RTTRST immediately reloads and restarts the clock divider with the new programmed value. This also resets the 32-bit counter.

When not used, the RTT can be disabled in order to suppress dynamic power consumption in this module. This can be achieved by setting RTT_MR.RTTDIS.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 32.2. RTT Counting

The RTTINC2 flag is set when the number of prescaler roll-overs programmed through the SELINC2 field in the RTT Modulo Selection register (RTT_MODR) has been reached since the last read of RTT_SR.



For example, it is possible to generate two sources of interrupt of different periods with flags RTTINC and RTTINC2. If the RTT slow clock frequency is 32.768 kHz and RTPRES=32, the RTTINC flag rises 1024 times per second (less than 1 ms period). If the field SELINC2=5, the RTTINC2 flag rises once per second.

If RTTINC is defined as the unique source of interrupt (RTTINCEN=1, ALMIEN=0 and INC2AEN=0 in RTT_MR), the value read in RTT_SR by the interrupt handler determines if the current interrupt event corresponds to a 1-second event (RTT_SR[2:1]=3) or to a 1-millisecond event (RTT_SR[2:1]=1). See the figure below.

If the bit INC2AEN=1, RTTINC2 flag is also a source for the RTT alarm signal. See RTT Block Diagram.

Reset	0	0	0	0	0	0	0	0

Bit 24 – RTC1HZ Real-Time Clock 1Hz Clock Selection

Value	Description
0	The RTT 32-bit counter is driven by the 16-bit prescaler roll-over events.
1	The RTT 32-bit counter is driven by the 1Hz RTC clock.

Bit 21 – INC2AEN RTTINC2 Alarm and Interrupt Enable

Value	Description
0	The RTTINC2 flag is not a source of the RTT alarm signal nor a source of interrupt.
1	The RTTINC2 flag is a source of the RTT alarm signal and a source of interrupt.

Bit 20 – RTTDIS Real-Time Timer Disable

Value	Description
0	The RTT is enabled.
1	The RTT is disabled (no dynamic power consumption).

Bit 18 – RTTRST Real-Time Timer Restart

Value	Description
0	No effect.
1	Reloads and restarts the clock divider with the new programmed value. This also resets the 32-bit counter.

Bit 17 – RTTINCIEN Real-Time Timer Increment Interrupt Enable

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	The RTT_SR.RTTINC bit has no effect on interrupt.
1	The RTT_SR.RTTINC bit asserts interrupt.

Bit 16 – ALMIEN Alarm Interrupt Enable

Value	Description
0	The RTT_SR.ALMS bit has no effect on interrupt.
1	The RTT_SR.ALMS bit asserts interrupt.

Bits 15:0 – RTPRES[15:0] Real-Time Timer Prescaler Value

Defines the number of RTT slow clock periods required to increment the Real-Time Timer. The RTTINCIEN bit must be cleared prior to writing a new RTPRES value.
RTPRES is defined as follows:

- RTPRES = 0: The prescaler period is equal to 2^{16} * slow clock periods.
- RTPRES = 1 or 2: forbidden.
- RTPRES ≠ 0, 1 or 2: The prescaler period is equal to RTPRES * slow clock periods.

© 2026 Microchip Technology Inc. and its subsidiaries

32.5.2. Real-Time Timer Alarm Register

Name: RTT_AR
Offset: 0x04
Reset: 0xFFFFFFFF
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
	ALMV[31:24]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1

Bit	23	22	21	20	19	18	17	16
	ALMV[23:16]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1

Bit	15	14	13	12	11	10	9	8
	ALMV[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1

Bit	7	6	5	4	3	2	1	0

						RTTINC2	RTTINC	ALMS
Access						R	R	R
Reset						0	0	0

Bit 2 – RTTINC2 Predefined Number of Prescaler Roll-Overs Status (cleared on read)

Value	Description
0	SELINC2 = 0 or the number of prescaler roll-overs programmed through the SELINC2 field in RTT_MODR has not been reached since the last read of RTT_SR.
1	The number of prescaler roll-overs programmed through the SELINC2 field has been reached since the last read of RTT_SR.

Bit 1 – RTTINC Prescaler Roll-Over Status (cleared on read)

Value	Description
0	No prescaler roll-over occurred since the last read of RTT_SR.
1	Prescaler roll-over occurred since the last read of RTT_SR.

Bit 0 – ALMS Real-Time Alarm Status (cleared on read)

Value	Description
0	The real-time alarm has not occurred since the last read of RTT_SR.
1	The real-time alarm occurred since the last read of RTT_SR.

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						SELINC2[2:0]		
Access						R/W	R/W	R/W
Reset						0	0	0

Bits 2:0 – SELINC2[2:0] Selection of the 32-bit Counter Modulo to generate RTTINC2 Flag

Value	Name	Description
0	NO_RTTINC2	The RTTINC2 flag never rises.
1	MOD64	The RTTINC2 flag is set when CRTV modulo 64 equals 0.
2	MOD128	The RTTINC2 flag is set when CRTV modulo 128 equals 0.
3	MOD256	The RTTINC2 flag is set when CRTV modulo 256 equals 0.
4	MOD512	The RTTINC2 flag is set when CRTV modulo 512 equals 0.
5	MOD1024	The RTTINC2 flag is set when CRTV modulo 1024 equals 0. Example: If RTPRES=32 then RTTINC2 flag rises once per second if the slow clock is 32.768 kHz.
6	MOD2048	The RTTINC2 flag is set when CRTV modulo 2048 equals 0.
7	MOD4096	The RTTINC2 flag is set when CRTV modulo 4096 equals 0.

32.5.6. Real-Time Timer Timestamp Register

Name: RTT_TSR
Offset: 0x14
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	TS_OVF	TSTAMP[30:24]						
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	TSTAMP[23:16]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	TSTAMP[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	TSTAMP[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit 31 – TS_OVF Timestamp Overflow

Value	Description
0	RTT_ST.RTTINC2 was set but no new event occurred since the last read of RTT_SR.
1	RTT_ST.RTTINC2 was set and a second event occurred. To avoid any overflow, clear RTTINC2 by reading RTT_SR.

Bits 30:0 – TSTAMP[30:0] Real-Time Timer Value Timestamp
Each time an event triggers the flag RTT_SR.RTTINC2, RTT_VR.CRTV is copied into RTT_TSR.TSTAMP. The field TSTAMP remains stable until the next RTTINC2 event and can be used for event timestamping.

33. Real-Time Clock (RTC)

33.1. Description

The Real-Time Clock (RTC) peripheral is designed for very low power consumption. For optimal functionality, the RTC requires an accurate external 32.768 kHz clock, which can be provided by a crystal oscillator.

It combines a complete time-of-day clock with alarm and a Gregorian calendar, complemented by a programmable periodic interrupt. The alarm and calendar registers are accessed by a 32-bit data bus.

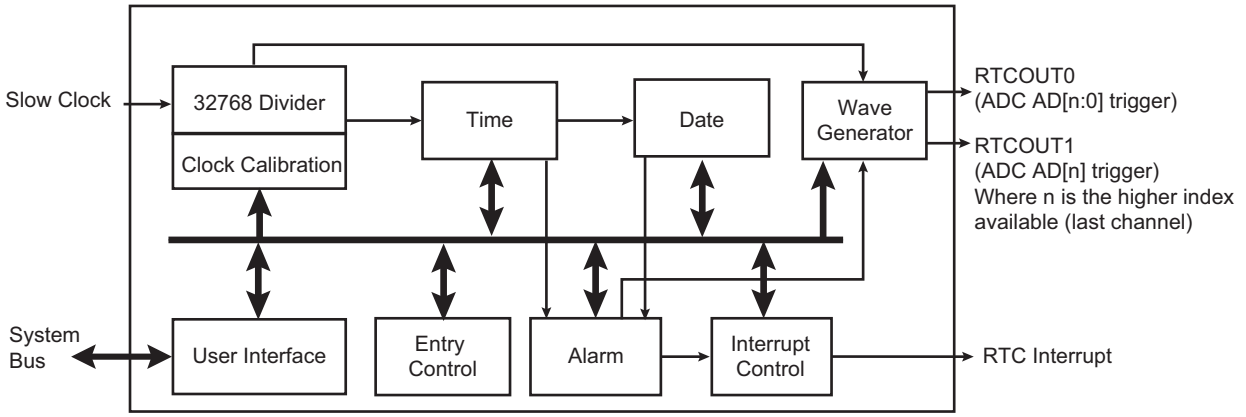
The RTC can also be configured for the UTC time format.

The time and calendar values are coded in binary-coded decimal (BCD) format. The time format can be 24-hour mode or 12-hour mode with an AM/PM indicator.

Updating time and calendar fields and configuring the alarm fields are performed by a parallel capture on the 32-bit data bus. An entry control is performed to avoid loading registers with incompatible BCD format data or with an incompatible date according to the current month/year/century.

A clock divider calibration circuitry can be used to compensate for crystal oscillator frequency variations.

Timestamping capability reports the first and last occurrences of tamper events.



33.2. Embedded Characteristics

- Full Asynchronous Design for Ultra Low-Power Consumption
- Gregorian and UTC Modes Supported
- Programmable Periodic Interrupt
- Safety/Security Features:
  - Valid time and date programming check
  - On-the-fly time and date validity check
- Counters Calibration Circuitry to Compensate for Crystal Oscillator Variations
- Waveform Generation for Trigger Event
- Tamper Control Registers and Detection Logic
- Tamper Timestamping Registers
- Register Write Protection

© 2026 Microchip Technology Inc. and its subsidiaries

33.3. Block Diagram

Figure 33.1. RTC Block Diagram

33.4. Product Dependencies

33.4.1. Power Management

The Real-Time Clock is continuously clocked at 32.768 kHz. The Power Management Controller (PMC) has no effect on RTC behavior.

33.4.2. Interrupt

Within the System Controller, the RTC interrupt is OR-wired with all the other module interrupts.

Only one System Controller interrupt line is connected on one of the internal sources of the interrupt controller.

RTC interrupt requires the interrupt controller to be programmed first.

When a System Controller interrupt occurs, the service routine must first determine the cause of the interrupt. This is done by reading each status register of the System Controller peripherals successively.

33.5. Functional Description

The RTC provides a full binary-coded decimal (BCD) clock that includes century (19/20), year (with leap years), month, date, day, hours, minutes and seconds reported in RTC Time Register (RTC_TIMR) and RTC Calendar Register (RTC_CALR).

The RTC can operate in UTC mode, giving the number of seconds elapsed since a reference time defined by the user (the UTC standard—ISO 8601—reference time is the 30th of June 1972). In this mode, the timefield is 32 bits wide and coded in hexadecimal format.

The valid year range is up to 2099 in Gregorian mode.

The RTC can operate in 24-hour mode or in 12-hour mode with an AM/PM indicator.

Corrections for leap years are included (all years divisible by 4 being leap years except 1900). This is correct up to the year 2099.

The RTC can generate events to trigger ADC measurements.

33.5.1. Reference Clock

The reference clock is the slow clock. It can be driven externally by a 32.768 kHz crystal, or internally.

© 2026 Microchip Technology Inc. and its subsidiaries

33.5.2. Timing

In Gregorian mode, the RTC is updated in real time at one-second intervals in Normal mode for the counters of seconds, at one-minute intervals for the counter of minutes and so on.

In UTC mode, the RTC is updated in real-time at one-second intervals (32-bit UTC counter default configuration).

Due to the asynchronous operation of the RTC with respect to the rest of the chip, to ensure that the value read in the RTC registers (century, year, month, date, day, hours, minutes, seconds) are valid and stable, it is necessary to read these registers twice. If the data is the same both times, then it is valid. Therefore, a minimum of two and a maximum of three accesses are required.

33.5.3. Alarm

In Gregorian mode, the RTC has five programmable fields: month, date, hours, minutes and seconds.

Each of these fields can be enabled or disabled to match the alarm condition:

- If all the fields are enabled, an alarm flag is generated (the corresponding flag is asserted and an interrupt generated if enabled) at a given month, date, hour/minute/second.
- If only the “seconds” field is enabled, then an alarm is generated every minute.

Depending on the fields that are enabled in the RTC Calendar Alarm register (RTC_CALALR) and the RTC Time Alarm register(RTC_TIMALR), a large number of possibilities are available to the user ranging from minutes to 365/366 days.

Note: To change one of the RTC_TIMALR.SEC, MIN, HOUR and/or RTC_CALALR.DATE, MONTH fields, it is recommended to disable the field before changing the value and then re-enable it after the change has been made. This requires up to three accesses to the RTC_TIMALR or RTC_CALALR. The first access clears the enable corresponding to the field to change (RTC_TIMALR.SECEN, MINEN, HOUREN and/or RTC_CALALR.DATEEN, MTHEN). If the field is already cleared, this access is not required. The second access performs the change of the value (RTC_TIMALR.SEC, MIN, HOUR and/or RTC_CALALR.DATE, MONTH). The third access is required to re-enable the field by writing 1 in RTC_TIMALR.SECEN, MINEN, HOUREN and/or RTC_CALALR.DATEEN, MTHEN.

In UTC mode, RTC_TIMALR must be configured to set the UTC alarm value and bit 0 in RTC_CALALR must be used to enable or disable the UTC alarm. If the UTC alarm is enabled, the alarm is generated once the UTC time matches the programmed UTC_TIME alarm field.

To change the UTC_TIME alarm field, proceed as follows:

1. Disable the UTC alarm by clearing RTC_CALALR.UTCEN if it is not already cleared.
2. Change the RTC_TIMALR.UTC_TIME alarm value.
3. Re-enable the UTC alarm by setting RTC_CALALR.UTCEN.

33.5.4. Error Checking when Programming

Verification on user interface data is performed when accessing the century, year, month, date, day, hours, minutes, seconds and alarms. A check is performed on illegal BCD entries such as illegal date of the month with regard to the year and century configured.

If one of the time fields is not correct, the data is not loaded into the register/counter and a flag is set in the validity register. The user can not reset this flag. It is reset as soon as an acceptable value is programmed. This avoids any further side effects in the hardware. The same procedure is followed for the alarm.

The following checks are performed:

1. Century (check if it is in range 19–20)
2. Year (BCD entry check)

© 2026 Microchip Technology Inc. and its subsidiaries

3. Date (check range 01–31)
4. Month (check if it is in BCD range 01–12, check validity regarding “date”)
5. Day (check range 1–7)
6. Hour (BCD checks: in 24-hour mode, check range 00–23 and check that AM/PM flag is not set if RTC is set in 24-hour mode; in 12-hour mode check range 01–12)
7. Minute (check BCD and range 00–59)
8. Second (check BCD and range 00–59)

Notes:

1. If the 12-hour mode is selected by means of the Mode register (RTC_MR), a 12-hour value can be programmed and the returned value on RTC_TIMR will be the corresponding 24-hour value. The entry control checks the value of the AM/PM indicator (bit 22 of RTC_TIMR) to determine the range to be checked.
2. In UTC mode, no check is performed on the entries. The RTC does not report any failure.

33.5.5. RTC Internal Free-Running Counter Error Checking

To improve the reliability and security of the RTC, a permanent check is performed on the internal free-running counters to report non-BCD or invalid date/time values.

An error is reported by RTC_SR.TDERR if an incorrect value has been detected. The flag can be cleared by setting the RTC_SCCR.TDERRCLR.

In all cases, RTC_SR.TDERR is set again if the source of the error has not been cleared before clearing RTC_SR.TDERR. The clearing of the source of such error can be done by reprogramming a correct value on RTC_CALR and/or RTC_TIMR.

The RTC internal free-running counters may automatically clear the source of RTC_SR.TDERR due to their roll-over (i.e., every 10 seconds for SECONDS[3:0] in RTC_TIMR). In this case, RTC_SR.TDERR is held high until a clear command is asserted by writing a 1 in RTC_SCCR.TDERRCLR.

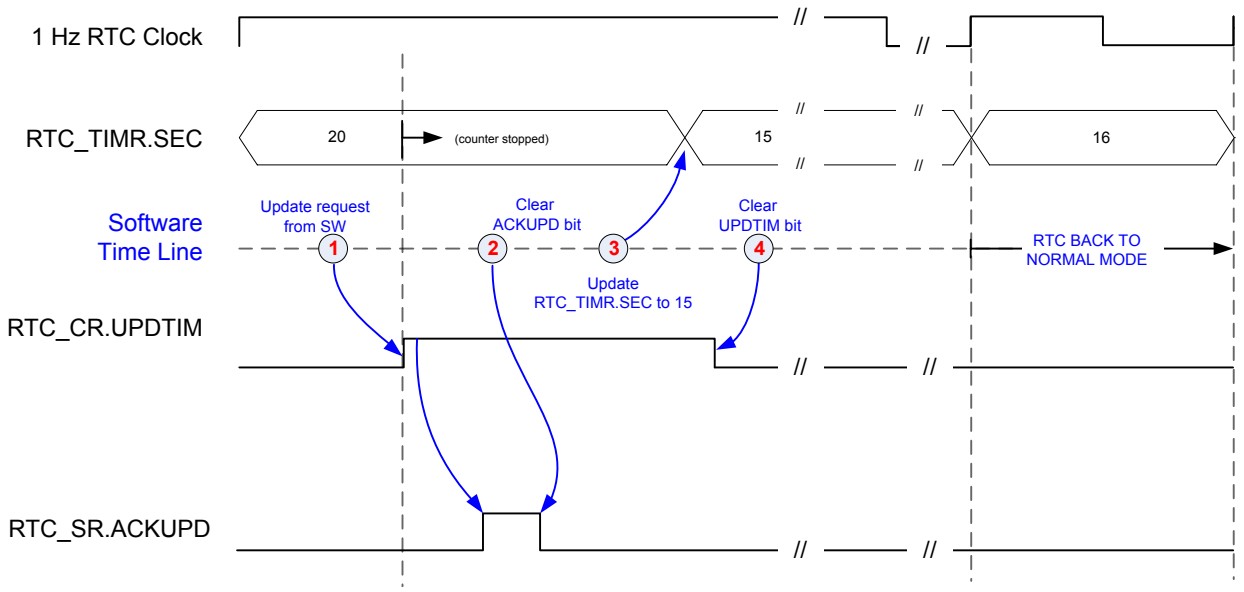
33.5.6. Updating Time/Calendar

33.5.6.1. Calendar Mode

To update time and date, the RTC must be stopped by setting the corresponding field in the Control register (RTC_CR). RTC_CR.UPDTIM must be set to update time fields (hour, minute, second) and RTC_CR.UPDCAL must be set to update calendar fields (century, year, month, date, day).

RTC_SR.ACKUPD must then be read to 1 by either polling RTC_SR or by enabling the acknowledge update interrupt by writing RTC_IER.ACKUPD to ‘1’. Once RTC_SR.ACKUPD is read to 1, it is mandatory to clear this flag by writing a 1 in RTC_SCCR.ACKCLR, after which the user can write to the Time register (RTC_TIMR), the Calendar register (RTC_CALR), or both.

Once the update is finished, the user must write a ‘0’ in RTC_CR.UPDTIM and/or RTC_CR.UPDCAL.



The timing sequence of the time/calendar update is described in the figure below.

When entering the Programming mode of the calendar fields, the time fields remain enabled. When entering the Programming mode of the time fields, both the time and the calendar fields are stopped. This is due to the location of the calendar logical circuitry (downstream for low-power considerations).

In successive update operations, the user must first check that RTC_CR.UPDTIM and RTC_CR.UPDCAL read 0 before writing these bits to ‘1’.

Figure 33.2. Time/Calendar Update Timing Diagram

© 2026 Microchip Technology Inc. and its subsidiaries

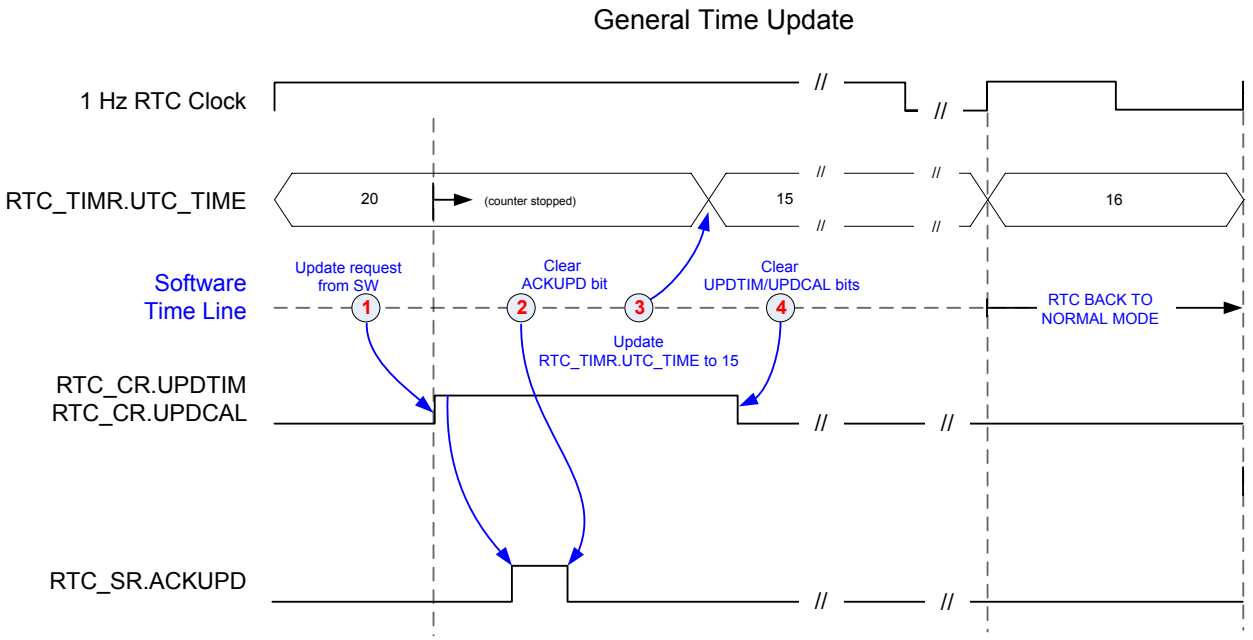
Figure 33.3. Calendar Mode Update Sequence

© 2026 Microchip Technology Inc. and its subsidiaries

33.5.6.2.UTC Mode

RTC_MR.HRMOD must be set to 0 prior to using the UTC mode.

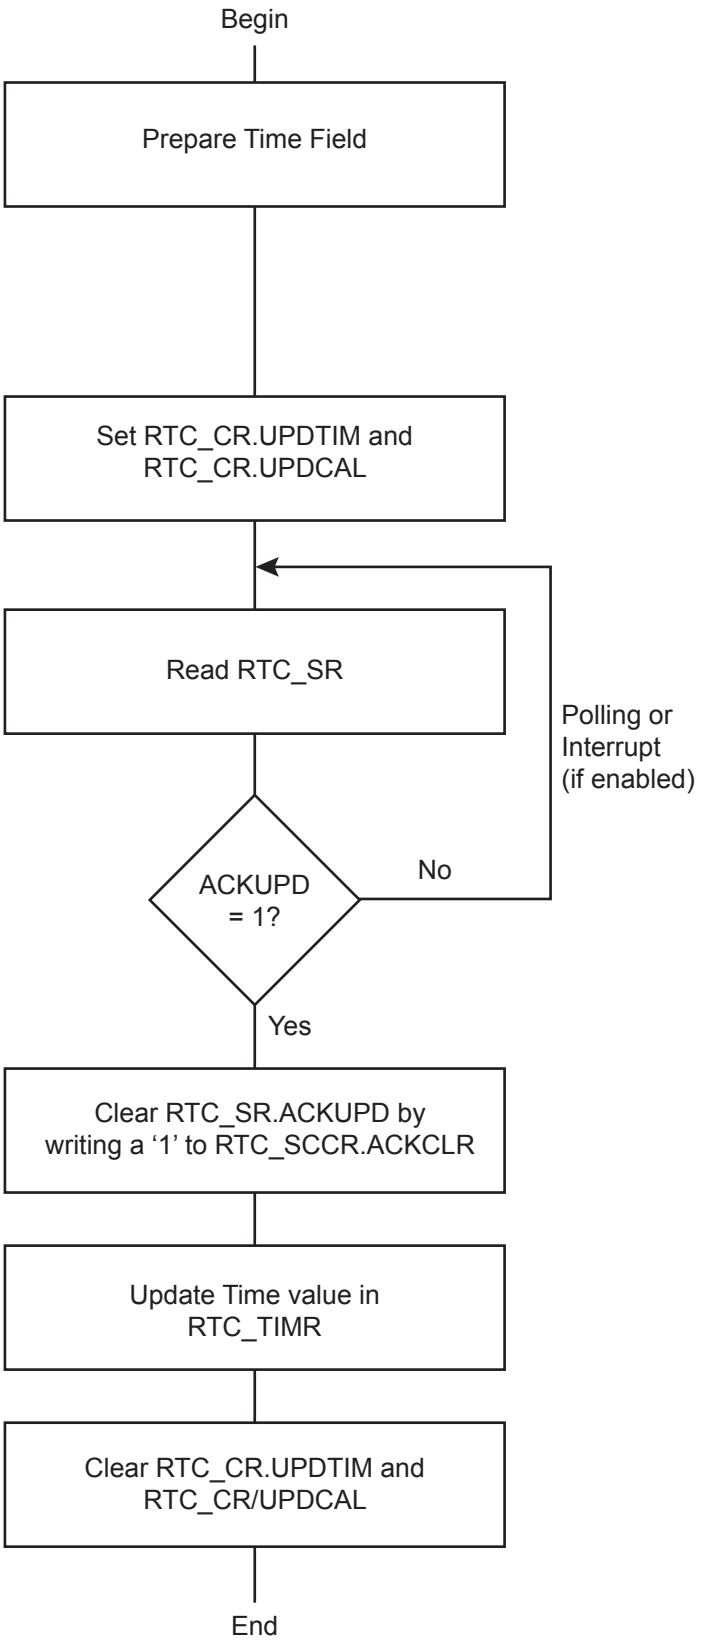
To update the UTC time, the RTC must be stopped by writing a 1 in RTC_CR.UPDTIM and RTC_CR.UPDCAL.



RTC_SR.ACKUPD must then be read to 1 by either polling RTC_SR or by enabling the acknowledge update interrupt by writing a 1 in RTC_IER.ACKUP. Once RTC_SR.ACKUPD is read to 1, it is mandatory to clear this flag by writing a 1 in RTC_SCCR.ACKCLR, after which the user can write to RTC_TIMR.

Once the update is finished, the user must write a 0 in RTC_CR.UPDTIM and a 0 in RTC_CR.UPCAL.

In successive update operations, the user must first check that RTC_CR.UPDTIM and RTC_CR.UPDCAL read 0 before writing a 1 in these bits.



The timing sequence of the UTC time update is described in the figure below.

Figure 33.4. UTC Time Update Timing Diagram

© 2026 Microchip Technology Inc. and its subsidiaries

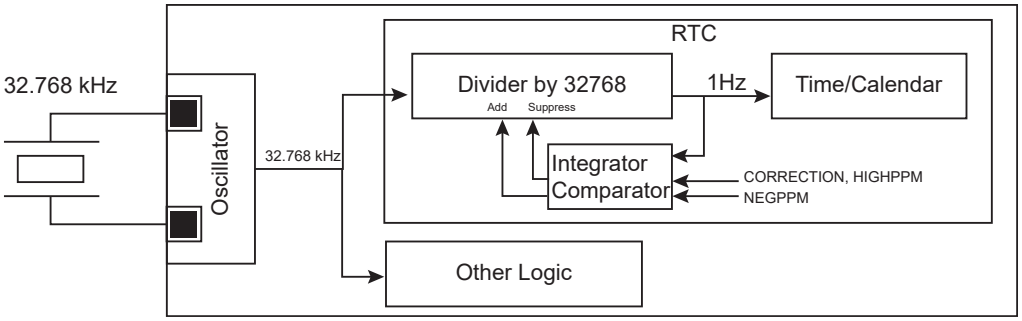
33.5.7. RTC Accurate Clock Calibration

The crystal oscillator that drives the RTC may not be as accurate as expected mainly due to temperature variation. The RTC is equipped with circuitry able to correct slow clock crystal drift.

To compensate for possible temperature variations over time, this accurate clock calibration circuitry can be programmed on-the-fly and also programmed during application manufacturing, in order to correct the crystal frequency accuracy at room temperature (20–25°C). The typical clock drift range at room temperature is ±20 ppm.

In the device operating temperature range, the 32.768 kHz crystal oscillator clock inaccuracy can be up to -200 ppm.

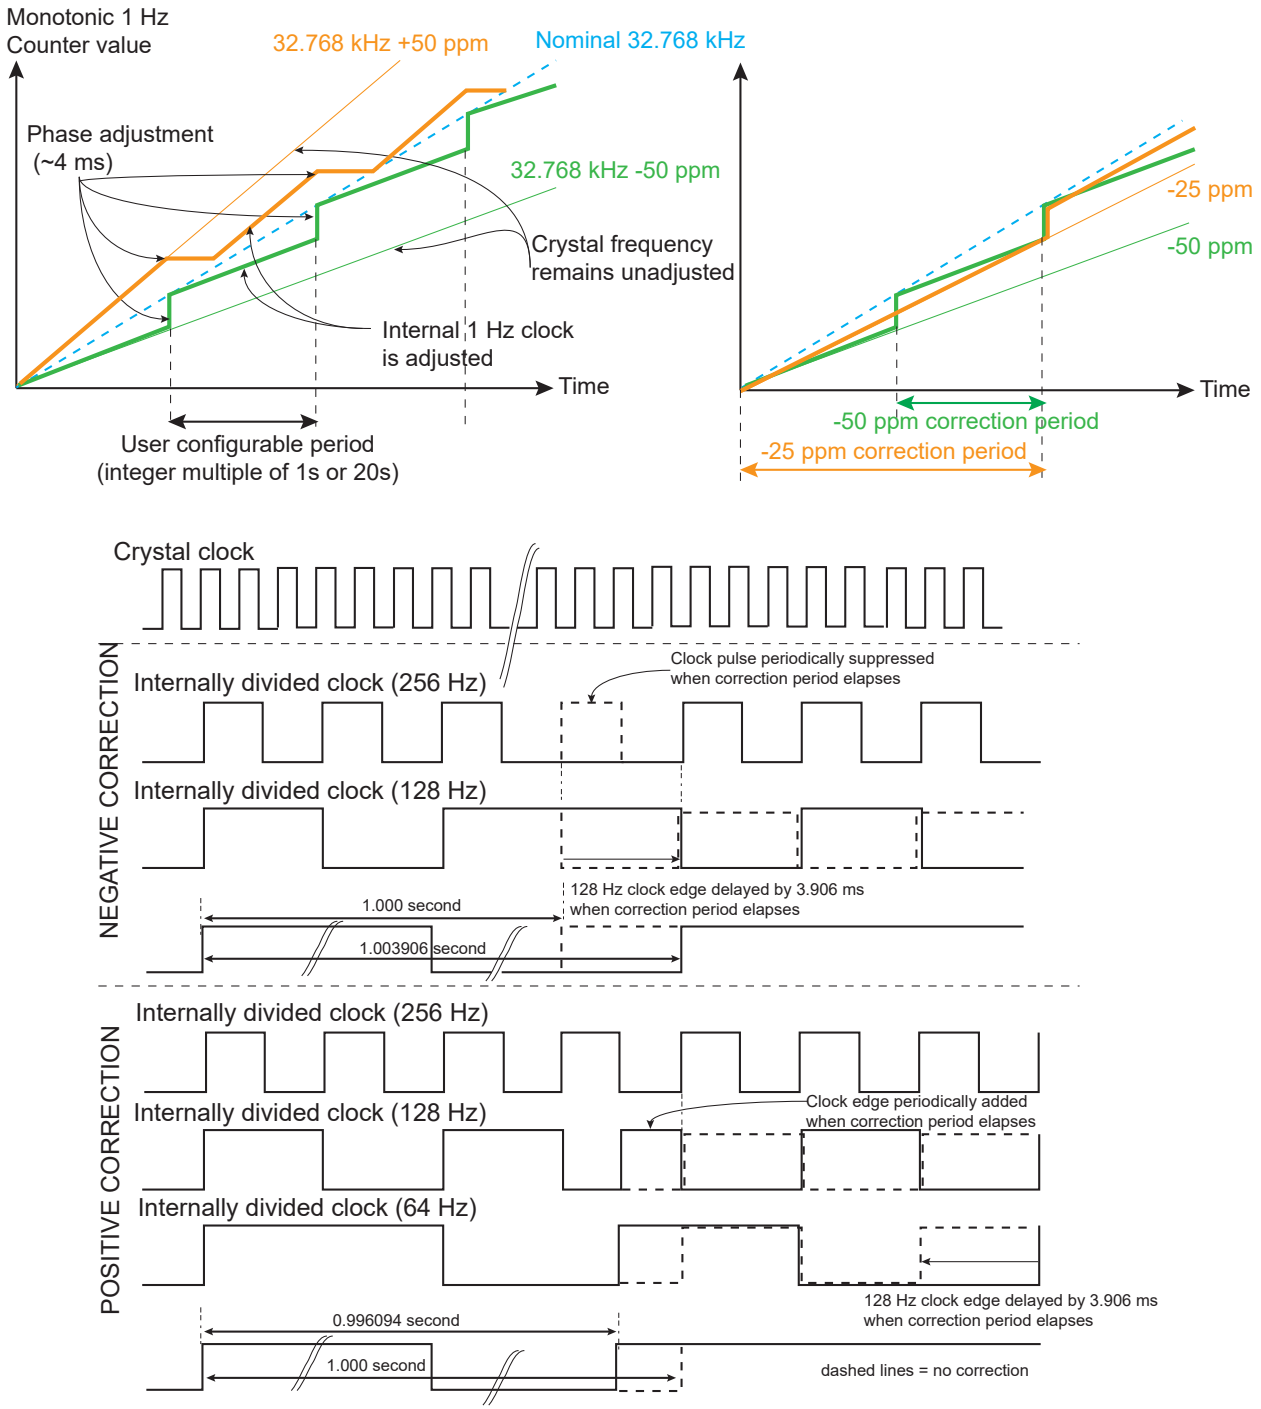
The RTC clock calibration circuitry allows positive or negative correction in a range of 1.5 ppm to 1950 ppm.



The calibration circuitry is fully digital. Thus, the configured correction is independent of temperature, voltage, process, etc., and no additional measurement is required to check that the correction is effective.

If the correction value configured in the calibration circuitry results from an accurate crystal frequency measure, the remaining accuracy is bounded by the values listed below:

- Below 1 ppm, for an initial crystal drift between 1.5 ppm up to 20 ppm, and from 30 ppm to 90 ppm
- Below 2 ppm, for an initial crystal drift between 20 ppm up to 30 ppm, and from 90 ppm to 130 ppm
- Below 5 ppm, for an initial crystal drift between 130 ppm up to 200 ppm



The calibration circuitry does not modify the 32.768 kHz crystal oscillator clock frequency, but it acts by slightly modifying the 1 Hz clock period from time to time. The correction event occurs every 1 + [(20 - (19 x HIGHPPM)) x CORRECTION] seconds. When the period is modified, depending on the sign of the correction, the 1 Hz clock period increases or reduces by around 4 ms. Depending on the CORRECTION, NEGPPM and HIGHPPM values configured in RTC_MR, the period interval between two correction events differs.

Figure 33.6. Calibration Circuitry

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 33.7. Calibration Circuitry Waveforms

Note that this adjustment does not take into account the temperature variation.

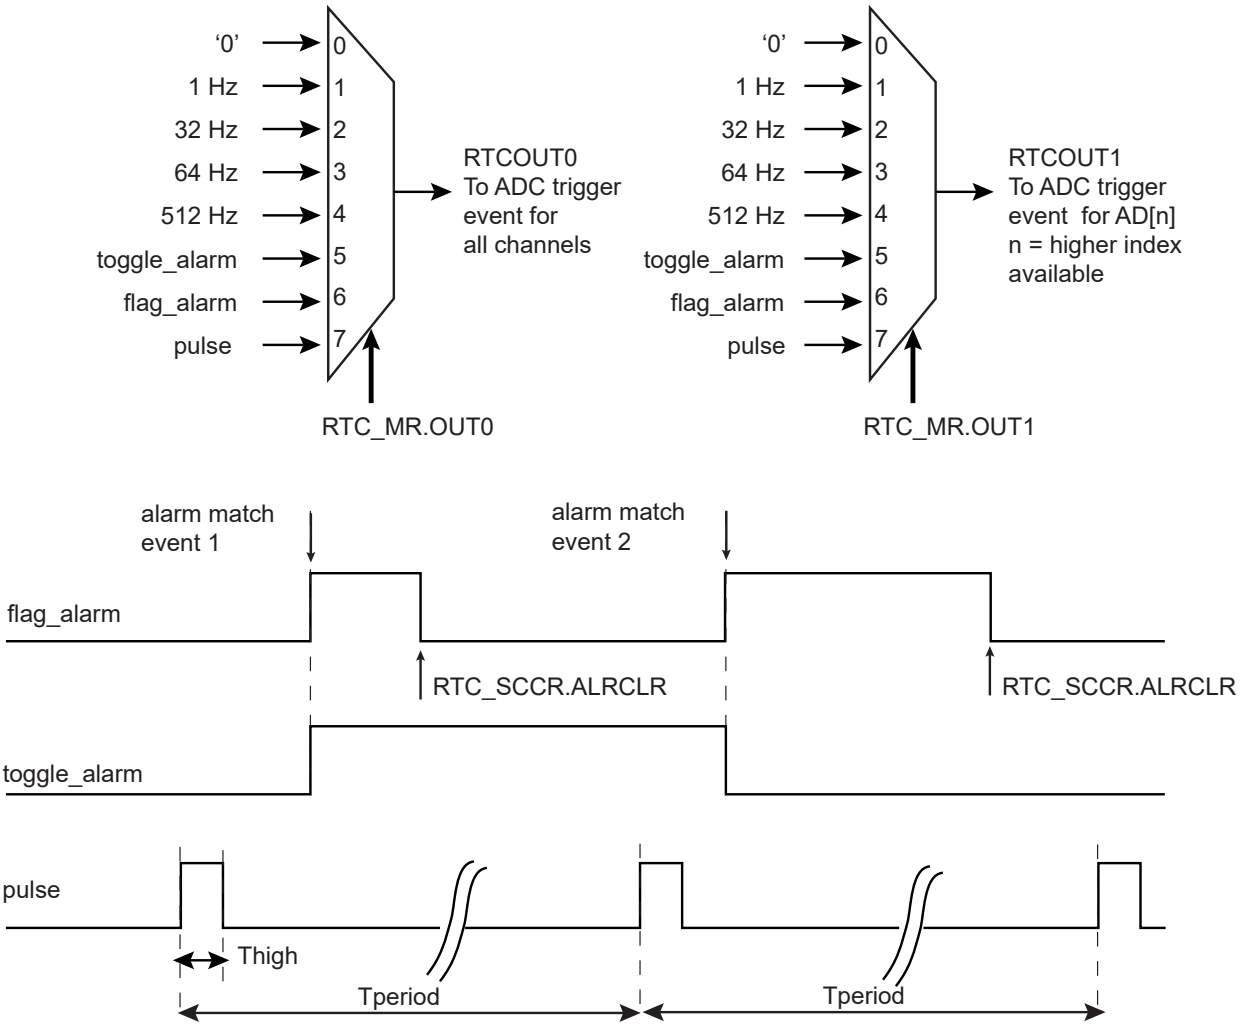
The frequency drift (up to -200 ppm) due to temperature variation can be compensated using a reference time if the application can access such a reference. If a reference time cannot be used, a temperature sensor can be placed close to the crystal oscillator in order to get the operating temperature of the crystal oscillator. Once obtained, the temperature may be converted using a

© 2026 Microchip Technology Inc. and its subsidiaries

lookup table (describing the accuracy/temperature curve of the crystal oscillator used) and RTC_MR configured accordingly. The calibration can be performed on-the-fly. This adjustment method is not based on a measurement of the crystal frequency/drift and therefore can be improved by means of the networking capability of the target application.

If no crystal frequency adjustment has been done during manufacturing, it is still possible to make adjustments. In the case where a reference time of the day can be obtained through a LAN/WAN network, it is possible to calculate the drift of the application crystal oscillator by comparing the values read on RTC_TIMR and RTC_CALR and programming RTC_MR.HIGHPPM and RTC_MR.CORRECTION according to the difference measured between the reference time and those of RTC_TIMR and RTC_CALR.

33.5.8. Waveform Generation



Waveforms can be generated in order to take advantage of the RTC inherent prescalers while the RTC is the only powered circuitry (Low-power mode of operation, Backup mode) or in any active mode. Entering Backup or Low-power operating modes does not affect the waveform generation outputs.

The RTC waveforms are internally routed to ADC trigger events and those events have a source driver selected among five possibilities. Two different triggers can be generated at a time, the first one is configurable in RTC_MR.OUT0, while the second trigger is configurable in RTC_MR.OUT1. RTC_MR.OUT0 manages the trigger for channel AD[n:0] (where n is the higher index available (last channel)), while RTC_MR.OUT1 manages the channel AD[n] only for specific modes. Refer to ADC_MR.TRGSEL in section “Analog-to-Digital Converter (ADC) Controller” for selection of the measurement triggers and associated modes of operation.

When RTC_MR.OUTx is set to 0, the associated output is stuck at 0 (reset value that can be used at any time to disable the waveform generation).

© 2026 Microchip Technology Inc. and its subsidiaries

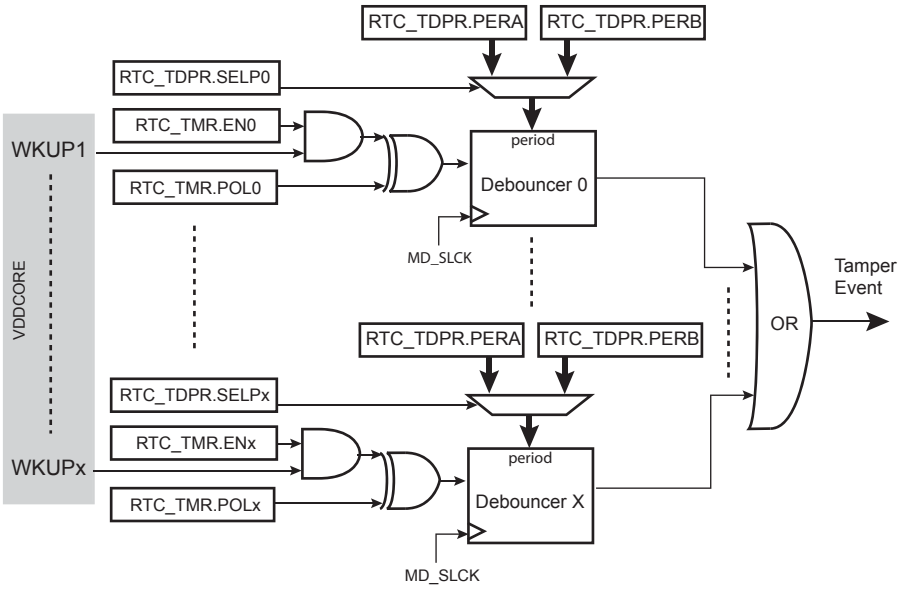
Figure 33.8. Waveform Generation for ADC Trigger Event

33.5.9. Tamper Control Registers and Detection Logic

The WKUP pins used for fast wake-up in PMC are also routed to the tamper detection logic. Any WKUP pin which is not already configured as source of fast wake-up can be configured and selected as a source of a tamper event.

The tamper event can be used to immediately clear (no peripheral clock required) the content of the GPBR, clear the keys stored in AES/TDES, clear the scrambling keys of QSPI/SDR/DDR/SMC memory controllers. Each of these peripherals embeds a configuration bit to allow/disallow the clear on tamper event.

The polarity of each of the WKUP pins can be configured.



Each of the WKUP pins is debounced prior to creating the tamper event.

The tamper event is asserted when one of the lines matches the configured polarity after the debouncing period (see the figure below).

The WKUP pins routed to tamper detection logic are all located on VDDCORE domain, thus there is no tamper detection event when the product is in Backup mode.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 33.9. Tamper Detection Circuitry

To enable WKUPx pin to be a source of tamper event, not already configured for a fast wake-up (refer to PMC configuration), the bit RTC_TMR.ENx must be written to 1.

The polarity of the WKUPx pin is configured in RTC_TMR.POLx.

Two debounce periods can be defined by configuring the fields RTC_TDPR.PERA and RTC_TDPR.PERB.

For each WKPUPx pin, the debounce period can be selected from either RTC_TDPR.PERA or RTC_TDPR.PERB by configuring the bit RTC_TDPR.SELPx.

For safety/security reasons, it is possible to lock the tamper configuration registers by writing RTC_TMR.TLOCK=1. Once written to 1, the only way to clear this bit is to perform a VDDCORE reset.

33.5.10. Tamper Timestamping

As soon as a tamper is detected, the tamper counter is incremented and the RTC stores the time of the day, the date and the source of the tamper event in registers located in the backup area. Up to two tamper events can be stored.

In UTC mode, only the UTC time is stored. The date information is not relevant.

The tamper counter saturates at 15. Once this limit is reached, the exact number of tamper occurrences since the last read of stamping registers cannot be known.

The first set of timestamping registers (RTC_TSTR0, RTC_TSDR0, RTC_TSSR0) cannot be overwritten. Once they have been written, all data are stored until the registers are reset. Thus these registers store the first tamper occurrence after a read.

The second set of timestamping registers (RTC_TSTR1, RTC_TSDR1, RTC_TSSR1) are overwritten each time a tamper event is detected. Thus the date and the time data of the first and the second stamping registers may be equal. This occurs when the tamper counter value carried on RTC_TSTR0.TEVCNT equals 1. Thus this second set of registers stores the last occurrence of tamper before a read.

Reading a set of timestamping registers requires three accesses, one for the time of the day, one for the date and one for the tamper source.

© 2026 Microchip Technology Inc. and its subsidiaries

Reading the third part (RTC_TSSR0/1) of a timestamping register set clears the whole content of the registers (time, date and tamper source) and makes the timestamping registers available to store a new event.

33.6.1. RTC Control Register

Name: RTC_CR
Offset: 0x00
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
							CALEVSEL[1:0]	
Access							R/W	R/W
Reset							0	0

Bit	15	14	13	12	11	10	9	8
							TIMEVSEL[1:0]	
Access							R/W	R/W
Reset							0	0

Bit	7	6	5	4	3	2	1	0
							UPDCAL	UPDTIM
Access							R/W	R/W
Reset							0	0

Bits 17:16 – CALEVSEL[1:0] Calendar Event Selection
The event that generates the flag CALEV in RTC_SR depends on the value of CALEVSEL
In UTC mode, this field has no effect on RTC_SR.

Value	Name	Description
0	WEEK	Week change (every Monday at time 00:00:00)
1	MONTH	Month change (every 01 of each month at time 00:00:00)
2	YEAR	Year change (every January 1 at time 00:00:00)
3	YEAR	Reserved

Bits 9:8 – TIMEVSEL[1:0] Time Event Selection
The event that generates the flag TIMEV in RTC_SR depends on the value of TIMEVSEL.
In UTC mode, this field has no effect on RTC_SR.

Value	Name	Description
0	MINUTE	Minute change
1	HOUR	Hour change
2	MIDNIGHT	Every day at midnight
3	NOON	Every day at noon

Bit 1 – UPDCAL Update Request Calendar Register
Calendar counting consists of day, date, month, year and century counters. Calendar counters can be programmed once this bit is set and acknowledged by the RTC_SR.ACKUPD bit.
In UTC mode, both UPDTIM and UPDCAL must be set to '1' in order to update the UTC time value.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
0	CLOSE_UPDATE	No effect or, if UPDCAL has been previously written to 1, stops the update procedure.
1	START_UPDATE	Stops the RTC calendar counting.

Bit 0 – UPDTIM Update Request Time Register

Time counting consists of second, minute and hour counters. Time counters can be programmed once this bit is set and acknowledged by the RTC_SR.ACKUPD bit.
In UTC mode, both UPDTIM and UPDCAL must be set to '1' in order to update the UTC time value.

Value	Name	Description
0	CLOSE_UPDATE	No effect or, if UPDTIM has been previously written to 1, stops the update procedure.
1	START_UPDATE	Stops the RTC time counting.

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.2. RTC Mode Register

Name: RTC_MR
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
			TPERIOD[1:0]			THIGH[2:0]		
Access			R/W	R/W		R/W	R/W	R/W
Reset			0	0		0	0	0

Bit	23	22	21	20	19	18	17	16
		OUT1[2:0]				OUT0[2:0]		
Access		R/W	R/W	R/W		R/W	R/W	R/W
Reset		0	0	0		0	0	0

Bit	15	14	13	12	11	10	9	8
	HIGHPPM	CORRECTION[6:0]						
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
				NEGPPM		UTC		HRMOD
Access				R/W		R/W		R/W
Reset				0		0		0

Bits 29:28 – TPERIOD[1:0] Period of the Output Pulse

Value	Name	Description
0	P_1S	1 second
1	P_500MS	500 ms
2	P_250MS	250 ms
3	P_125MS	125 ms

Bits 26:24 – THIGH[2:0] High Duration of the Output Pulse

Value	Name	Description
0	H_31MS	31.2 ms
1	H_16MS	15.6 ms
2	H_4MS	3.91 ms
3	H_976US	976 µs
4	H_488US	488 µs
5	H_122US	122 µs
6	H_30US	30.5 µs
7	H_15US	15.2 µs

Bits 22:20 – OUT1[2:0] ADC Last Channel Trigger Event Source Selection

Value	Name	Description
0	NO_WAVE	No waveform, stuck at ‘0’
1	FREQ1HZ	1-Hz square wave
2	FREQ32HZ	32-Hz square wave

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
3	FREQ64HZ	64-Hz square wave
4	FREQ512HZ	512-Hz square wave
5	ALARM_TOGGLE	Output toggles when alarm flag rises
6	ALARM_FLAG	Output is a copy of the alarm flag
7	PROG_PULSE	Duty cycle programmable pulse

Bits 18:16 – OUT0[2:0] All ADC Channel Trigger Event Source Selection

Value	Name	Description
0	NO_WAVE	No waveform, stuck at '0'
1	FREQ1HZ	1-Hz square wave
2	FREQ32HZ	32-Hz square wave
3	FREQ64HZ	64-Hz square wave
4	FREQ512HZ	512-Hz square wave
5	ALARM_TOGGLE	Output toggles when alarm flag rises
6	ALARM_FLAG	Output is a copy of the alarm flag
7	PROG_PULSE	Duty cycle programmable pulse

Bit 15 – HIGHPPM HIGH PPM Correction

If the absolute value of the correction to be applied is lower than 30 ppm, it is recommended to clear HIGHPPM. HIGHPPM set to 1 is recommended for 30 ppm correction and above.

Formula:

If HIGHPPM = 0, then the clock frequency correction range is from 1.5 ppm up to 98 ppm. The RTC accuracy is less than 1 ppm for a range correction from 1.5 ppm up to 30 ppm.

The correction field must be programmed according to the required correction in ppm; the formula is as follows:

$$\text{CORRECTION} = \frac{3906}{20 \times \text{ppm}} - 1$$

The value obtained must be rounded to the nearest integer prior to being programmed into CORRECTION field.

If HIGHPPM = 1, then the clock frequency correction range is from 30.5 ppm up to 1950 ppm. The RTC accuracy is less than 1 ppm for a range correction from 30.5 ppm up to 90 ppm.

The correction field must be programmed according to the required correction in ppm; the formula is as follows:

$$\text{CORRECTION} = \frac{3906}{\text{ppm}} - 1$$

The value obtained must be rounded to the nearest integer prior to being programmed into CORRECTION field.

If NEGPPM is set to 1, the ppm correction is negative (used to correct crystals that are faster than the nominal 32.768 kHz).

Value	Name	Description
0	DISABLED	Lower range ppm correction with accurate correction (below 30ppm correction)
1	ENABLED	Higher range ppm correction with accurate correction (higher than 30ppm correction)

Bits 14:8 – CORRECTION[6:0] Slow Clock Correction

Value	Name	Description
0	DISABLED	No correction
1–127	–	The slow clock will be corrected according to the formula given in HIGHPPM description.

Bit 4 – NEGPPM Negative PPM Correction

See CORRECTION and HIGHPPM field descriptions.

NEGPPM must be cleared to correct a crystal slower than 32.768 kHz.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
0	DISABLED	Positive correction (the divider will be slightly higher than 32768)
1	ENABLED	Negative correction (the divider will be slightly lower than 32768)

Bit 2 – UTC UTC Time Format

HRMOD must be set to 0 prior to using the UTC mode.

Value	Name	Description
0	DISABLED	Gregorian calendar
1	ENABLED	UTC format

Bit 0 – HRMOD 12-/24-hour Mode

HRMOD must be set to 0 prior to using the UTC mode.

Value	Name	Description
0	24HOURS	24-hour mode is selected.
1	AMPM	12-hour mode is selected.

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.3. RTC Time Register (Default Mode)

Name: RTC_TIMR (DEFAULT_MODE)
Offset: 0x08
Reset: 0x00000000
Property: Read/Write

In UTC mode, this register view is not relevant, see RTC_TIMALR (UTC_MODE).

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
		AMPM	HOUR[5:0]					
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
		MIN[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
		SEC[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	0

Bit 22 – AMPM Ante Meridiem Post Meridiem Indicator
This bit is the AM/PM indicator in 12-hour mode.

Value	Description
0	AM.
1	PM.

Bits 21:16 – HOUR[5:0] Current Hour
The range that can be set is 1–12 (BCD) in 12-hour mode or 0–23 (BCD) in 24-hour mode.

Bits 14:8 – MIN[6:0] Current Minute
The range that can be set is 0–59 (BCD).
The lowest four bits encode the units. The higher bits encode the tens.

Bits 6:0 – SEC[6:0] Current Second
The range that can be set is 0–59 (BCD).
The lowest four bits encode the units. The higher bits encode the tens.

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.4. RTC Time Register (UTC_MODE)

Name: RTC_TIMR (UTC_MODE)
Offset: 0x08
Reset: 0x00000000
Property: Read/Write

This configuration is relevant only if UTC = 1 in RTC_MR.

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
	UTC_TIME[31:24]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	UTC_TIME[23:16]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	UTC_TIME[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	UTC_TIME[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – UTC_TIME[31:0] Current UTC Time
Any value can be set.

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.5. RTC Calendar Register

Name: RTC_CALR
Offset: 0x0C
Reset: 0x01E11320
Property: Read/Write

In UTC mode, values read in this register are not relevant.

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
			DATE[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	0	1

Bit	23	22	21	20	19	18	17	16
	DAY[2:0]			MONTH[4:0]				
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	0	0	0	0	1

Bit	15	14	13	12	11	10	9	8
	YEAR[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	1	0	0	1	1

Bit	7	6	5	4	3	2	1	0
		CENT[6:0]						
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	1	0	0	0	0	0

Bits 29:24 – DATE[5:0] Current Day in Current Month
The range that can be set is 01–31 (BCD).
The lowest four bits encode the units. The higher bits encode the tens.

Bits 23:21 – DAY[2:0] Current Day in Current Week
The range that can be set is 1–7 (BCD).
The coding of the number (which number represents which day) is user-defined as it has no effect on the date counter.

Bits 20:16 – MONTH[4:0] Current Month
The range that can be set is 01–12 (BCD).
The lowest four bits encode the units. The higher bits encode the tens.

Bits 15:8 – YEAR[7:0] Current Year
The range that can be set is 00–99 (BCD).
The lowest four bits encode the units. The higher bits encode the tens.

Bits 6:0 – CENT[6:0] Current Century
The range that can be set is 20 (Gregorian).
The lowest four bits encode the units. The higher bits encode the tens.
Note: Value 20 (BCD) is always written in CENT whatever the value entered, thus there is no trigger event on RTC_VER.NVCAL regarding CENT.

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.6. RTC Time Alarm Register (Default Mode)

Name: RTC_TIMALR (DEFAULT_MODE)
Offset: 0x10
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

To change one of the SEC, MIN, HOUR fields, it is recommended to disable the field before changing the value and then re-enable it after the change has been made. This requires up to three accesses to RTC_TIMALR. The first access clears the enable corresponding to the field to change (SECEN, MINEN, HOUREN). If the field is already cleared, this access is not required. The second access performs the change of value (SEC, MIN, HOUR). The third access is required to re-enable the field by writing 1 in the SECEN, MINEN, HOUREN fields.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	HOUREN	AMPM	HOUR[5:0]					
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	MINEN	MIN[6:0]						
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	SECEN	SEC[6:0]						
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 23 – HOUREN Hour Alarm Enable

Value	Name	Description
0	DISABLED	The hour-matching alarm is disabled.
1	ENABLED	The hour-matching alarm is enabled.

Bit 22 – AMPM AM/PM Indicator
If RTC_MR.HRMOD is set to 0, the RTC_TIMALR.HOUR field must respect the 24-hour time format, and AMPM must always be set to 0.
If RTC_MR.HRMOD is set to 1, the RTC_TIMALR.HOUR field must respect the 12-hour time format, and AMPM must be set to 0 to indicate an AM time or to 1 to indicate a PM time.

Bits 21:16 – HOUR[5:0] Hour Alarm
This field is the alarm field corresponding to the BCD-coded hour counter.

Bit 15 – MINEN Minute Alarm Enable

Value	Name	Description
0	DISABLED	The minute-matching alarm is disabled.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
1	ENABLED	The minute-matching alarm is enabled.

Bits 14:8 – MIN[6:0] Minute Alarm
This field is the alarm field corresponding to the BCD-coded minute counter.

Bit 7 – SECEN Second Alarm Enable

Value	Name	Description
0	DISABLED	The second-matching alarm is disabled.
1	ENABLED	The second-matching alarm is enabled.

Bits 6:0 – SEC[6:0] Second Alarm
This field is the alarm field corresponding to the BCD-coded second counter.

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.7. RTC Time Alarm Register (UTC_MODE)

Name: RTC_TIMALR (UTC_MODE)
Offset: 0x10
Reset: 0x00000000
Property: Read/Write

This configuration is relevant only if UTC = 1 in RTC_MR.

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
	UTC_TIME[31:24]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	UTC_TIME[23:16]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	UTC_TIME[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	UTC_TIME[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – UTC_TIME[31:0] UTC_TIME Alarm

This field is the alarm field corresponding to the UTC time counter. To change it, proceed as follows:
1. Disable the UTC alarm by clearing RTC_CALALR.UTCEN if it is not already cleared.
2. Change the UTC_TIME alarm value.
3. Enable the UTC alarm by setting RTC_CALALR.UTCEN.

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.8. RTC Calendar Alarm Register (Default Mode)

Name: RTC_CALALR (DEFAULT_MODE)
Offset: 0x14
Reset: 0x01010000
Property: Read/Write

In UTC mode, this register view is not relevant, see RTC_CALALR (UTC_MODE).

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

To change one of the DATE, MONTH fields, it is recommended to disable the field before changing the value and then re-enable it after the change has been made. This requires up to three accesses to RTC_CALALR. The first access clears the enable corresponding to the field to change (DATEEN, MTHEN). If the field is already cleared, this access is not required. The second access performs the change of the value (DATE, MONTH). The third access is required to re-enable the field by writing 1 in DATEEN, MTHEN fields.

Bit	31	30	29	28	27	26	25	24
	DATEEN		DATE[5:0]					
Access	R/W		R/W	R/W	R/W	R/W	R/W	R/W
Reset	0		0	0	0	0	0	1

Bit	23	22	21	20	19	18	17	16
	MTHEN			MONTH[4:0]				
Access	R/W			R/W	R/W	R/W	R/W	R/W
Reset	0			0	0	0	0	1

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
Access								
Reset								

Bit 31 – DATEEN Date Alarm Enable

Value	Name	Description
0	DISABLED	The date-matching alarm is disabled.
1	ENABLED	The date-matching alarm is enabled.

Bits 29:24 – DATE[5:0] Date Alarm
This field is the alarm field corresponding to the BCD-coded date counter.

Bit 23 – MTHEN Month Alarm Enable

Value	Name	Description
0	DISABLED	The month-matching alarm is disabled.
1	ENABLED	The month-matching alarm is enabled.

Bits 20:16 – MONTH[4:0] Month Alarm
This field is the alarm field corresponding to the BCD-coded month counter.

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.9. RTC Calendar Alarm Register (UTC_MODE)

Name: RTC_CALALR (UTC_MODE)
Offset: 0x14
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								UTCEN
Access								R/W
Reset								0

Bit 0 – UTCEN UTC Alarm Enable

Value	Name	Description
0	DISABLED	The UTC-matching alarm is disabled.
1	ENABLED	The UTC-matching alarm is enabled.

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.10. RTC Status Register

Name: RTC_SR
Offset: 0x18
Reset: 0x00000004
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			TDERR	CALEV	TIMEV	SEC	ALARM	ACKUPD
Access			R	R	R	R	R	R
Reset			0	0	0	1	0	0

Bit 5 – TDERR Time and/or Date Free Running Error
If the RTC is configured in UTC mode, the value returned by this field is not relevant.

Value	Name	Description
0	CORRECT	The internal free running counters are carrying valid values since the last read of the Status register (RTC_SR).
1	ERR_TIMEDATE	The internal free running counters have been corrupted (invalid date or time, non-BCD values) since the last read and/or they are still invalid.

Bit 4 – CALEV Calendar Event
The calendar event is selected in RTC_CR.TIMEVSEL and can be any one of the following events: week change, month change and year change. If the RTC is configured in UTC mode, the value returned by this field is not relevant.

Value	Name	Description
0	NO_CALEVENT	No calendar event has occurred since the last clear.
1	CALEVENT	At least one calendar event has occurred since the last clear.

Bit 3 – TIMEV Time Event
The time event is selected in RTC_CR.TIMEVSEL and can be any one of the following events: minute change, hour change, noon, midnight (day change). If the RTC is configured in UTC mode, the value returned by this field is not relevant.

Value	Name	Description
0	NO_TIMEVENT	No time event has occurred since the last clear.
1	TIMEVENT	At least one time event has occurred since the last clear.

Bit 2 – SEC Second Event

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
0	NO_SECEVENT	No second event has occurred since the last clear.
1	SECEVENT	At least one second event has occurred since the last clear.

Bit 1 – ALARM Alarm Flag

Value	Name	Description
0	NO_ALARMEVENT	No alarm matching condition occurred.
1	ALARMEVENT	An alarm matching condition has occurred.

Bit 0 – ACKUPD Acknowledge for Update

Value	Name	Description
0	FREERUN	Time and calendar registers cannot be updated.
1	UPDATE	Time and calendar registers can be updated.

33.6.11. RTC Status Clear Command Register

Name: RTC_SCCR
Offset: 0x1C
Reset: –
Property: Write-only

To avoid missing clearing commands, wait for three slow clock cycles between two accesses to this register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Clears the corresponding status flag in the Status register (RTC_SR).

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			TDERRCLR	CALCLR	TIMCLR	SECCLR	ALRCLR	ACKCLR
Access			W	W	W	W	W	W
Reset			–	–	–	–	–	–

Bit 5 – TDERRCLR Time and/or Date Free Running Error Clear
If the RTC is configured in UTC mode, this bit has no effect.

Bit 4 – CALCLR Calendar Clear
If the RTC is configured in UTC mode, this bit has no effect.

Bit 3 – TIMCLR Time Clear
If the RTC is configured in UTC mode, this bit has no effect.

Bit 2 – SECCLR Second Clear

Bit 1 – ALRCLR Alarm Clear

Bit 0 – ACKCLR Acknowledge Clear

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.12. RTC Interrupt Enable Register

Name: RTC_IER
Offset: 0x20
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			TDERREN	CALEN	TIMEN	SECEN	ALREN	ACKEN
Access			W	W	W	W	W	W
Reset			–	–	–	–	–	–

Bit 5 – TDERREN Time and/or Date Error Interrupt Enable
If the RTC is configured in UTC mode, this bit has no effect.

Bit 4 – CALEN Calendar Event Interrupt Enable
If the RTC is configured in UTC mode, this bit has no effect.

Bit 3 – TIMEN Time Event Interrupt Enable
If the RTC is configured in UTC mode, this bit has no effect.

Bit 2 – SECEN Second Event Interrupt Enable

Bit 1 – ALREN Alarm Interrupt Enable

Bit 0 – ACKEN Acknowledge Update Interrupt Enable

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.13. RTC Interrupt Disable Register

Name: RTC_IDR
Offset: 0x24
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the System Controller Write Protection Mode register (SYSC_WPMR).

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			TDERRDIS	CALDIS	TIMDIS	SECDIS	ALRDIS	ACKDIS
Access			W	W	W	W	W	W
Reset			–	–	–	–	–	–

Bit 5 – TDERRDIS Time and/or Date Error Interrupt Disable
If the RTC is configured in UTC mode, this bit has no effect.

Bit 4 – CALDIS Calendar Event Interrupt Disable
If the RTC is configured in UTC mode, this bit has no effect.

Bit 3 – TIMDIS Time Event Interrupt Disable
If the RTC is configured in UTC mode, this bit has no effect.

Bit 2 – SECDIS Second Event Interrupt Disable

Bit 1 – ALRDIS Alarm Interrupt Disable

Bit 0 – ACKDIS Acknowledge Update Interrupt Disable

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.14. RTC Interrupt Mask Register

Name: RTC_IMR
Offset: 0x28
Reset: 0x00000000
Property: Read-only

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is disabled.

1: The corresponding interrupt is enabled.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access

Bit	7	6	5	4	3	2	1	0
			TDERR	CAL	TIM	SEC	ALR	ACK
Access			R	R	R	R	R	R
Reset			0	0	0	0	0	0

Bit 5 – TDERR Time and/or Date Error Mask
If the RTC is configured in UTC mode, this bit has no effect.

Bit 4 – CAL Calendar Event Interrupt Mask
If the RTC is configured in UTC mode, this bit is not relevant.

Bit 3 – TIM Time Event Interrupt Mask
If the RTC is configured in UTC mode, this bit is not relevant.

Bit 2 – SEC Second Event Interrupt Mask

Bit 1 – ALR Alarm Interrupt Mask

Bit 0 – ACK Acknowledge Update Interrupt Mask

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.15. RTC Valid Entry Register

Name: RTC_VER
Offset: 0x2C
Reset: 0x00000000
Property: Read-only

If the RTC is configured in UTC mode, the values returned by this register are not relevant.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
					NVCALALR	NVTIMALR	NVCAL	NVTIM
Access					R	R	R	R
Reset					0	0	0	0

Bit 3 – NVCALALR Non-valid Calendar Alarm

Value	Description
0	No invalid data has been detected in RTC_CALALR (Calendar Alarm register).
1	RTC_CALALR has contained invalid data since it was last programmed.

Bit 2 – NVTIMALR Non-valid Time Alarm

Value	Description
0	No invalid data has been detected in RTC_TIMALR (Time Alarm register).
1	RTC_TIMALR has contained invalid data since it was last programmed.

Bit 1 – NVCAL Non-valid Calendar

Value	Description
0	No invalid data has been detected in RTC_CALR (Calendar register).
1	RTC_CALR has contained invalid data since it was last programmed.

Bit 0 – NVTIM Non-valid Time

Value	Description
0	No invalid data has been detected in RTC_TIMR (Time register).
1	RTC_TIMR has contained invalid data since it was last programmed.

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.16. RTC TimeStamp Time Register 0 (Default Mode)

Name: RTC_TSTR0 (DEFAULT_MODE)
Offset: 0xB0
Reset: 0x00000000
Property: Read-only

These fields are valid for non-UTC mode only.

RTC_TSTR0 reports the timestamp of the first tamper event after reading RTC_TSSR0.

Bit	31	30	29	28	27	26	25	24
	BACKUP				TEVCNT[3:0]			
Access	R				R	R	R	R
Reset	0				0	0	0	0

Bit	23	22	21	20	19	18	17	16
		AMPM	HOUR[5:0]					
Access		R	R	R	R	R	R	R
Reset		0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
		MIN[6:0]						
Access		R	R	R	R	R	R	R
Reset		0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
		SEC[6:0]						
Access		R	R	R	R	R	R	R
Reset		0	0	0	0	0	0	0

Bit 31 – BACKUP System Mode of the Tamper (cleared by reading RTC_TSSR0)

Value	Description
0	The state of the system is different from Backup mode when the tamper event occurs.
1	The system is in Backup mode when the tamper event occurs.

Bits 27:24 – TEVCNT[3:0] Tamper Events Counter (cleared by reading RTC_TSSR0)
Each time a tamper event occurs, this counter is incremented. This counter saturates at 15. Once this value is reached, it is no longer possible to know the exact number of tamper events.
If this field is not null, this implies that at least one tamper event occurred since the last register reset and that the values stored in timestamping registers are valid.

Bit 22 – AMPM AM/PM Indicator of the Tamper (cleared by reading RTC_TSSR0)

Bits 21:16 – HOUR[5:0] Hours of the Tamper (cleared by reading RTC_TSSR0)

Bits 14:8 – MIN[6:0] Minutes of the Tamper (cleared by reading RTC_TSSR0)

Bits 6:0 – SEC[6:0] Seconds of the Tamper (cleared by reading RTC_TSSR0)

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.17. RTC TimeStamp Time Register 0 (UTC_MODE)

Name: RTC_TSTR0 (UTC_MODE)
Offset: 0xB0
Reset: 0x00000000
Property: Read-only

RTC_TSTR0 reports the timestamp of the first tamper event after reading RTC_TSSR0.

Bit	31	30	29	28	27	26	25	24
	BACKUP				TEVCNT[3:0]			
Access	R				R	R	R	R
Reset	0				0	0	0	0

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
Access								
Reset								

Bit 31 – BACKUP System Mode of the Tamper (cleared by reading RTC_TSSR0)

Value	Description
0	The state of the system is different from Backup mode when the tamper event occurs.
1	The system is in Backup mode when the tamper event occurs.

Bits 27:24 – TEVCNT[3:0] Tamper Events Counter (cleared by reading RTC_TSSR0)
Each time a tamper event occurs, this counter is incremented. This counter saturates at 15. Once this value is reached, it is no more possible to know the exact number of tamper events.
If this field is not null, this implies that at least one tamper event occurred since last register reset and that the values stored in timestamping registers are valid.

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.18. RTC TimeStamp Date Register (Default Mode)

Name: RTC_TSDR0 (DEFAULT_MODE)
Offset: 0xB4
Reset: 0x00000000
Property: Read-only

RTC_TSDR0 reports the timestamp of the first tamper event after reading RTC_TSSR0, and RTC_TSDR1 reports the timestamp of the last tamper event.

The fields contain the date and the source of a tamper occurrence if RTC_TSTR0.TEVCNT is not null.

Bit	31	30	29	28	27	26	25	24
			DATE[5:0]					
Access			R	R	R	R	R	R

Bits 29:24 – DATE[5:0] Date of the Tamper (cleared by reading RTC_TSSR0)

Bits 23:21 – DAY[2:0] Day of the Tamper (cleared by reading RTC_TSSR0)

Bits 20:16 – MONTH[4:0] Month of the Tamper (cleared by reading RTC_TSSR0)

Bits 15:8 – YEAR[7:0] Year of the Tamper (cleared by reading RTC_TSSR0)

Bits 6:0 – CENT[6:0] Century of the Tamper (cleared by reading RTC_TSSR0)

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.19. RTC TimeStamp Date Register 0 (UTC_MODE)

Name: RTC_TSDR0 (UTC_MODE)
Offset: 0xB4
Reset: 0x00000000
Property: Read-only

RTC_TSDR0 reports the timestamp of the first tamper event after reading RTC_TSSR0, and RTC_TSDR1 reports the timestamp of the last tamper event.
This register is cleared by reading RTC_TSSR0.

Bit	31	30	29	28	27	26	25	24
	UTC_TIME[31:24]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

33.6.20. RTC TimeStamp Source Register 0

Name: RTC_TSSR0
Offset: 0xB8
Reset: 0x00000000
Property: Read-only

This register is cleared after read, and the read access also performs a clear on RTC_TSTR0 and RTC_TSDR0.
The following configuration values are valid for all listed bit names of this register:

0: No alarm generated since the last clear of this register.

1: An alarm has been generated by the corresponding monitor since the last read of this register.

Bits 0, 1, 2, 3, 4, 5, 6, 7 – DETx Tamper Detection on VDDCORE WKUP[8:1] (cleared on read)

© 2026 Microchip Technology Inc. and its subsidiaries

33.6.21. RTC TimeStamp Time Register 1 (Default Mode)

Name: RTC_TSTR1 (DEFAULT_MODE)
Offset: 0xBC
Reset: 0x00000000
Property: Read-only

RTC_TSTR1 reports the timestamp of the last tamper event after reading RTC_TSSR1.

The fields contain the date and the source of a tamper occurrence if RTC_TSTR0.TEVCNT is greater than 1.

Bit	31	30	29	28	27	26	25	24

33.6.24. RTC TimeStamp Date Register 1 (UTC_MODE)

Name: RTC_TSDR1 (UTC_MODE)
Offset: 0xC0
Reset: 0x00000000
Property: Read-only

RTC_TSDR0 reports the timestamp of the first tamper event after reading RTC_TSSR0, and RTC_TSDR1 reports the timestamp of the last tamper event.
This register is cleared by reading RTC_TSSR1.

Bit	31	30	29	28	27	26	25	24

Reset	0	0	0	0	0	0	0	0

Bit 31 – TRLOCK Tamper Registers Lock (Write-once, cleared by VDDCORE reset)

Value	Name	Description
0	UNLOCKED	RTC_TMR and RTC_TDPR can be written.
1	LOCKED	RTC_TMR and RTC_TDPR cannot be written until the next VDDCORE domain reset.

Bits 16, 17, 18, 19, 20, 21, 22, 23 – POLx WKUPx+1 Polarity

Value	Name	Description
0	LOW	If the source of tamper remains low for a debounce period, a tamper event is generated.
1	HIGH	If the source of tamper remains high for a debounce period, a tamper event is generated.

Bits 0, 1, 2, 3, 4, 5, 6, 7 – ENx WKUPx+1 Tamper Source Enable

Value	Name	Description
0	DISABLE	WKUP pin index x+1 is not enabled as a source of tamper.
1	ENABLE	WKUP pin index x+1 is enabled as a source of tamper.

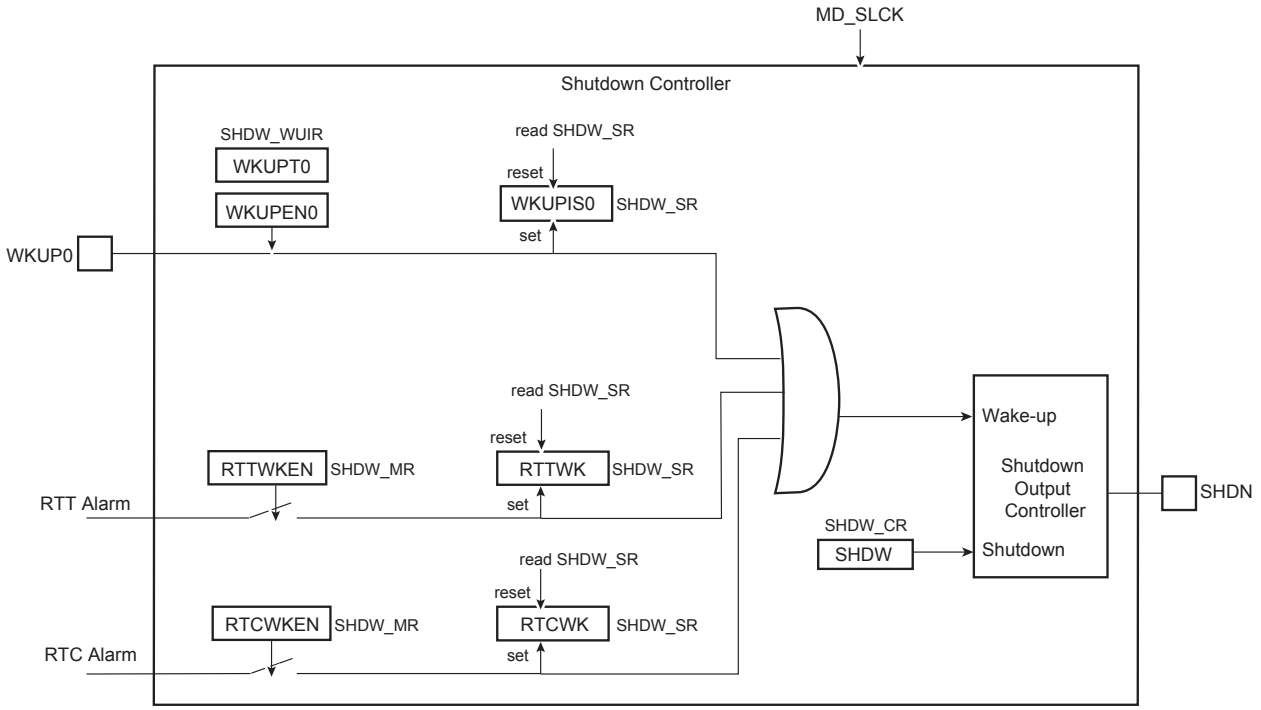
34. Shutdown Controller (SHDWC)

34.1. Description



The Shutdown Controller (SHDWC) controls the SHDN output signal (to enable and disable an external power supply circuit), and manages the wake-up events detection.

34.2. Embedded Characteristics

- Shutdown Logic
  - Software assertion of the Shutdown Output Pin (SHDN)
  - Programmable de-assertion from wake-up events
- Wake-Up Logic
  - Programmable wake-up event detection input pins, and internal wake-up event from RTC and RTT

34.3. Block Diagram

Figure 34.1. SHDWC Block Diagram

34.4. I/O Lines Description

Table 34.1. I/O Lines Description

Name	Description	Type
WKUP0	Wake-up input	Input
SHDN	Shutdown output	Output

© 2026 Microchip Technology Inc. and its subsidiaries

34.5. Product Dependencies

34.5.1. Power Management

The SHDWC is continuously clocked by the Monitoring Domain Slow Clock (MD_SLCK). The Power Management Controller has no effect on the behavior of the SHDWC.

34.6. Functional Description

The SHDWC manages the main power supply. To do so, it is supplied with VDDBU and manages wake-up input pins and one output pin, SHDN.

A typical application connects the pin SHDN to the enable input of the device's power supply circuit. The wake-up inputs (WKUP0) connect to any push-buttons or signal that wake up the system.

The software is able to control the pin SHDN by writing the Control register (SHDW_CR) with the bit SHDW at 1. The shutdown is taken into account only two MD_SLCK cycles after the write of SHDW_CR. This register is password-protected and so the value written should contain the correct key for the command to be taken into account. As a result, the SHDN pin is driven low and the system should be powered down.

34.6.1. Wake-Up Inputs

Any level change on the WKUP pin can trigger a wake-up. Wake-up is configured in the Mode register (SHDW_MR) and Wake-Up Inputs register (SHDW_WUIR). The transition detector can be programmed to detect either a positive or negative transition on the WKUP pin. The detection can also be disabled. Programming is performed by enabling the bit Wake-up Input (WKUPEN0) and defining the bit Wake-up Input Type (WKUPT0) in SHDW_WUIR.

Moreover, a debouncing circuit can be programmed for WKUP. The debouncing circuit filters pulses on WKUP shorter than the programmed value in SHDW_MR.WKUPDBC. If the programmed level change is detected on a pin, a counter starts. When the counter reaches the value programmed in WKUPDBC, the SHDN pin is released. If a new input change is detected before the counter reaches the corresponding value, the counter is stopped and cleared. WKUPIS0 of the Status register (SHDW_SR) reports the detection of the programmed events on WKUP with a reset after the read of SHDW_SR.

The SHDWC can be programmed to activate the wake-up using the RTC and RTT alarms (detection of the rising edge event is synchronized with SLCK). This is done by writing SHDW_MR.RTCWKEN and RTTWKEN. When enabled, the detection of RTC and RTT alarms is reported in SHDW_SR.RTCWK and RTTWK. They are cleared after reading SHDW_SR. When using the RTC and RTT alarms to wake up the system, the user must ensure that the RTC and RTT alarm status flags are cleared before shutting down the system. Otherwise, no rising edge of the status flags may be detected and the wake-up fails.

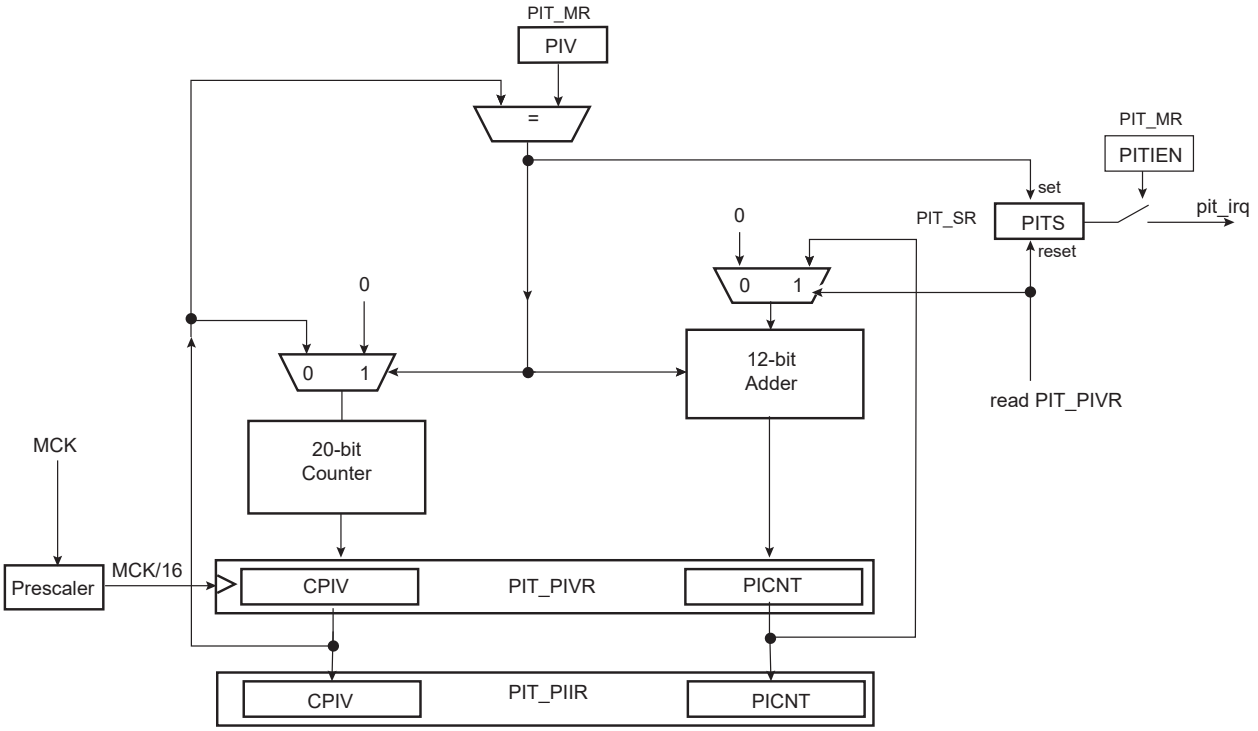
35. Periodic Interval Timer (PIT)

35.1. Description



The Periodic Interval Timer (PIT) provides the operating system's scheduler interrupt. It is designed to offer maximum accuracy and efficient management, even for systems with long response time.

35.2. Embedded Characteristics

- 20-bit Programmable Counter plus 12-bit Interval Counter
- Reset-on-read Feature
- Both Counters Work on Main System Bus Clock/16

35.3. Block Diagram

Figure 35.1. Periodic Interval Timer

35.4. Functional Description

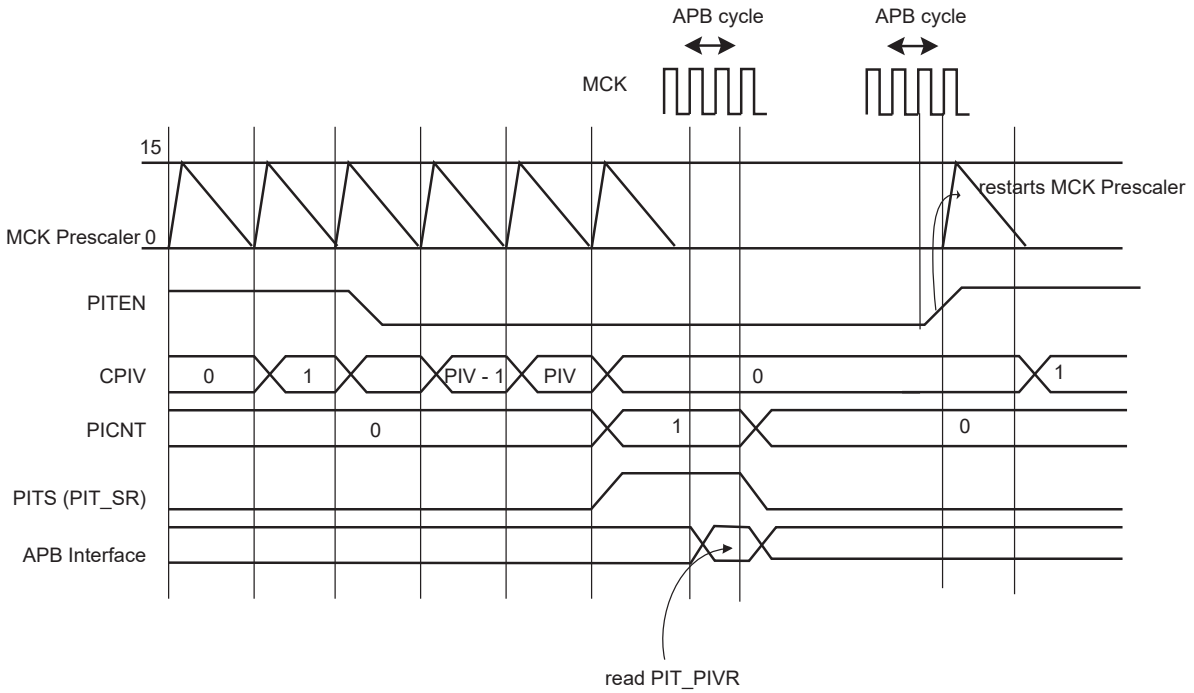
The Periodic Interval Timer (PIT) provides periodic interrupts for use by operating systems.

The PIT provides a programmable overflow counter and a reset-on-read feature. It is built around two counters: a 20-bit CPIV counter and a 12-bit PICNT counter. Both counters work at Main System Bus Clock /16.

The 20-bit CPIV counter increments from 0 up to a programmable overflow value set in the field PIV of the Mode register (PIT_MR). When the counter CPIV reaches this value, it resets to 0 and increments PICNT. The status bit PITS in the Status register (PIT_SR) rises and triggers an interrupt, provided the interrupt is enabled (PIT_MR.PITIEN).

Writing a new PIV value in PIT_MR does not reset/restart the counters.

© 2026 Microchip Technology Inc. and its subsidiaries



When CPIV and PICNT values are obtained by reading the Periodic Interval Value register (PIT_PIVR), the overflow counter (PICNT) is reset and PIT_SR.PITS is cleared, thus acknowledging the interrupt. The value of PICNT gives the number of periodic intervals elapsed since the last read of PIT_PIVR.

When CPIV and PICNT values are obtained by reading the Periodic Interval Image Register (PIT_PIIR), there is no effect on the counters CPIV and PICNT, nor on the bit PITS. For example, a profiler can read PIT_PIIR without clearing any pending interrupt, whereas a timer interrupt clears the interrupt by reading PIT_PIVR.

The PIT may be enabled/disabled using PIT_MR.PITEN (disabled on reset). PITEN only becomes effective when the CPIV value is 0. The figure below illustrates the PIT counting. After PITEN is reset (PITEN = 0), the CPIV goes on counting until the PIV value is reached, and is then reset. PIT restarts counting, only if PITEN is set again.

The PIT is stopped when the core enters debug state.

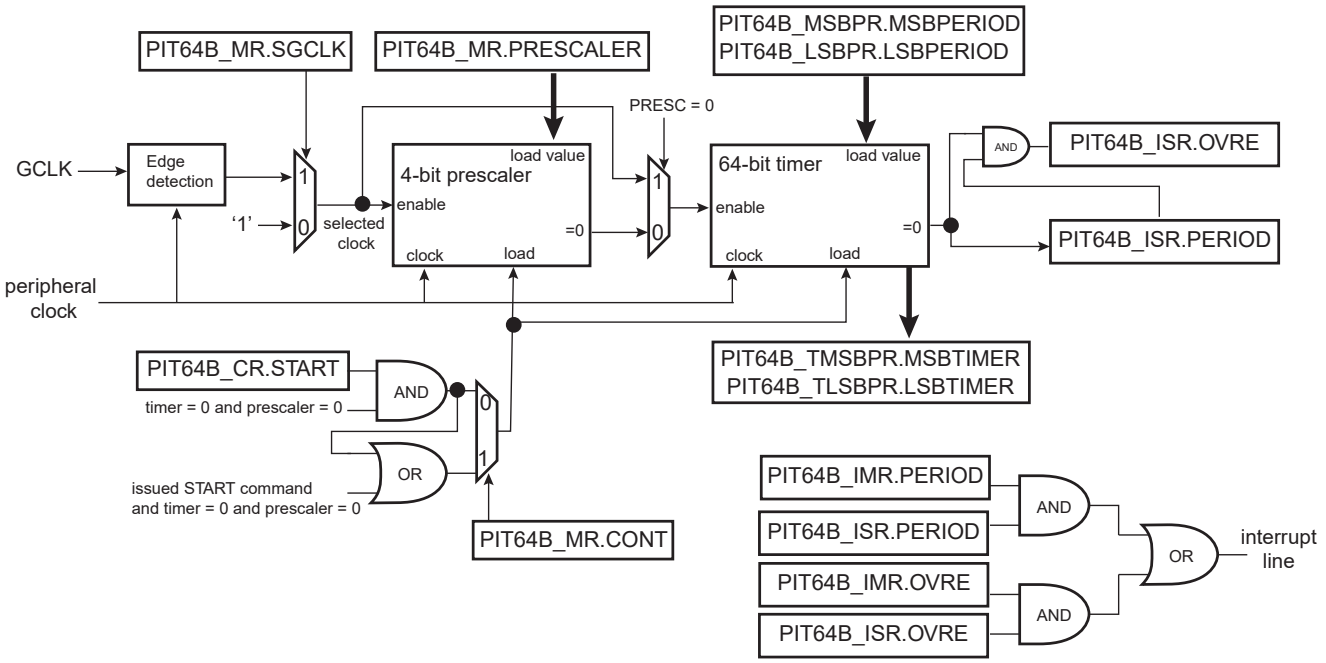
36. 64-bit Periodic Interval Timer (PIT64B)

36.1. Description



The 64-bit Periodic Interval Timer (PIT64B) provides the operating system scheduler interrupt, as well as any periodic source of interrupt to software. It is designed to offer maximum accuracy and efficient management, even for systems with long response times.

36.2. Embedded Characteristics

- 4-bit Prescaler
- 64-bit Timer
- Single Shot or Continuous Mode
- Safety/Security Access Reports
- Register Write protection

36.3. Block Diagram

Figure 36.1. PIT64B Block Diagram

36.4. Product Dependencies

36.4.1. Power Management

The Power Management Controller (PMC) controls the PIT64B clock in order to save power. The programmer must first enable the PIT64B clock in the PMC before using the PIT64B.

After a hardware reset, the PIT64B clock is disabled by default.

36.4.2. Interrupt Generation

The PIT64B interface has an interrupt line connected to the Interrupt Controller.

Handling the PIT64B interrupt requires programming the Interrupt Controller before configuring the PIT64B.

© 2026 Microchip Technology Inc. and its subsidiaries

36.5. Functional Description

36.5.1. Timer Clock Source

The two clock sources for the 64-bit timer are the peripheral clock and the generic clock (GCLK), which can be fully asynchronous to the peripheral clock. The selected clock can be prescaled before triggering the 64-bit timer.

The GCLK is selected as source clock for the prescaler when the SGCLK bit, in the Mode register (PIT64B_MR), is written to 1. The prescaler is active as soon as PIT64B_MR.PRESCALER>0.

If PIT64B_MR.PRESCALER=0, the timer is triggered either on each rising edge detection event of the GCLK if PIT64B_MR.SGCLK is written to 1, or on each rising edge of the peripheral clock.

If GCLK is selected, the frequency must be at least 3 times lower than the peripheral clock.

36.5.2. Single Period Mode

When the PIT64B_MR.CONT bit is written to 0, the PIT64B produces a single timer event. The timer period starts as soon as the START bit, in the Control register (PIT64B_CR), is written to 1. The period is defined by configuring the LSBPERIOD field in the LSB Period register (PIT64B_LSBPR) and the MSBPERIOD field in the MSB Period register (PIT64B_MSBPR). When the START command is issued, the 64-bit timer loads 0 and increments up to LSBPERIOD and MSBPERIOD field value minus 1, then automatically reloads 0 and stops.

When time reaches the maximum value, the PERIOD flag, in the Interrupt Status register (PIT64B_ISR), is set. No other period will be started until a new START command is issued.

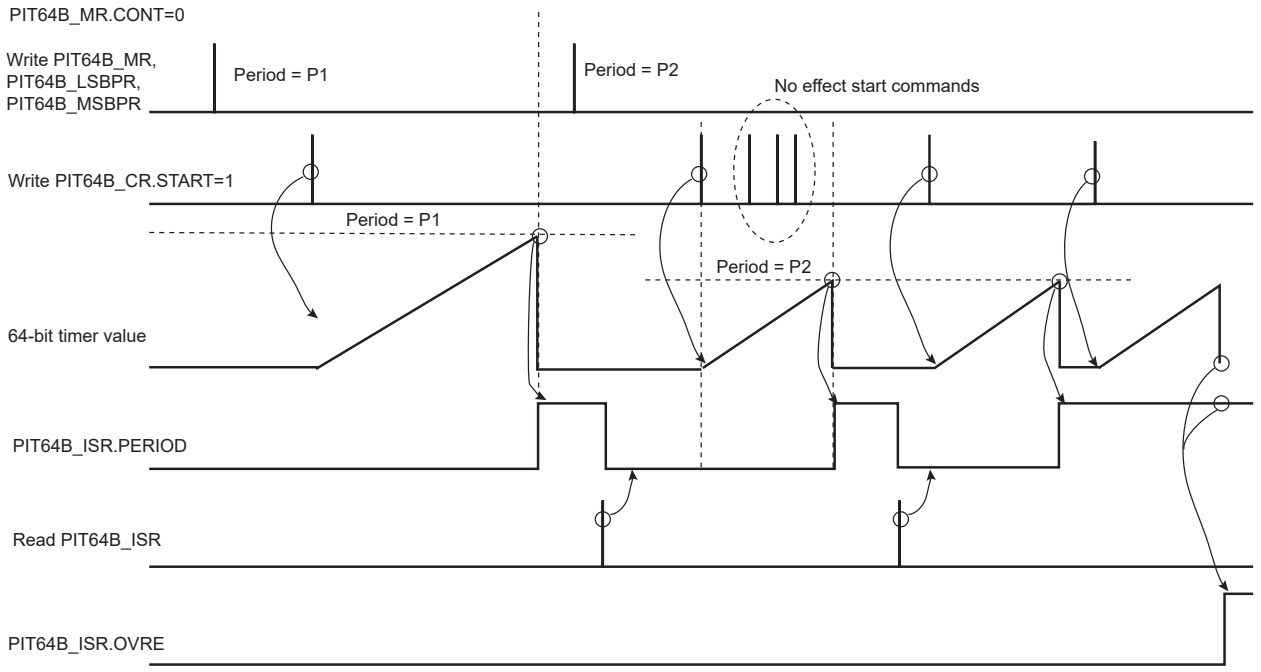
After a period is started and while it is not elapsed, any new values written in PIT64B_MR, PIT64B_LSBPR or PIT64B_MSBPR have no effect on the current period if bit PIT64B_MR.SMOD=0 (see Figure 36.2)

If PIT64B_MR.SMOD=1 a start is also performed as soon as PIT64B_LSBPR is written, thus a modification of the period can be performed on-the-fly with a single write operation if the period requires no more than 32 bits. When writing a 64-bit value, the 32-bit MSB part must be configured first, followed by the 32-bit LSB part (see Figure 36.3). When configuring a value lower or equal to 32 bits after processing a period defined on 64 bits, first PIT64B_MSBPR must be written to 0, and then the 32-bit LSB must be written into PIT64B_LSBPR.

If PIT64B_CR.SWRST is written to 1, the current period is immediately stopped.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 36.2. Single Waveform in Single Period Mode if bit PIT64B_MR.SMOD=0



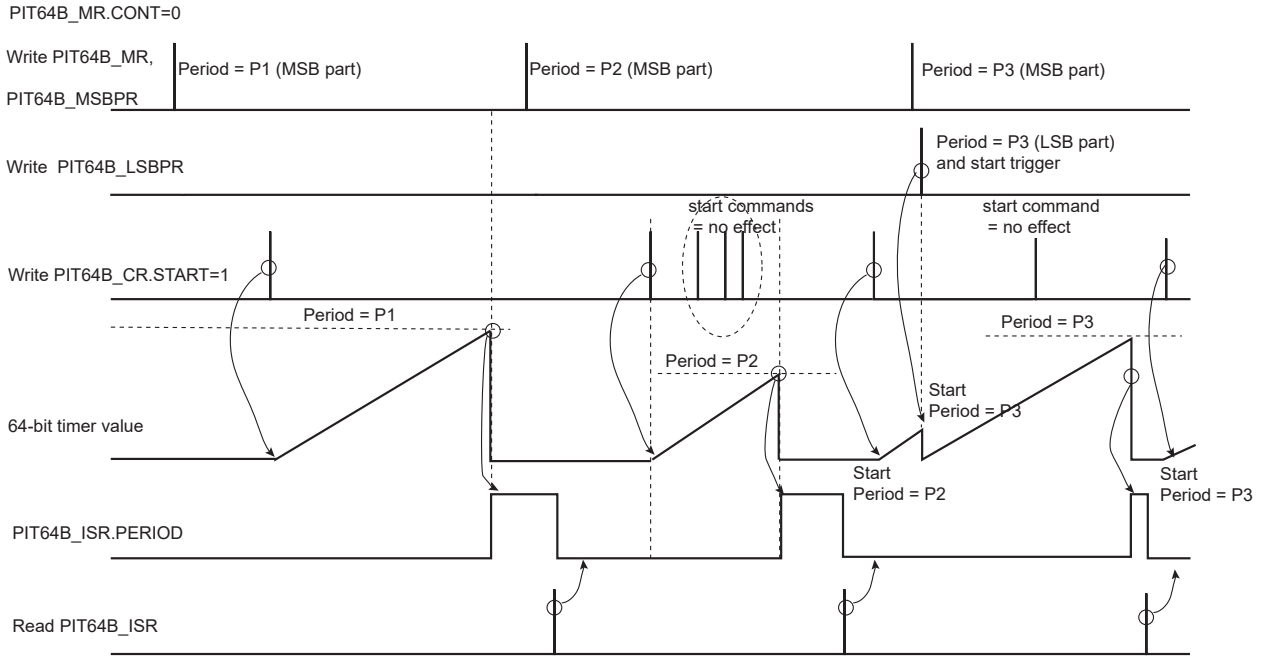


Figure 36.3. Waveform in Single Period Mode if bit PIT64B_MR.SMOD=1

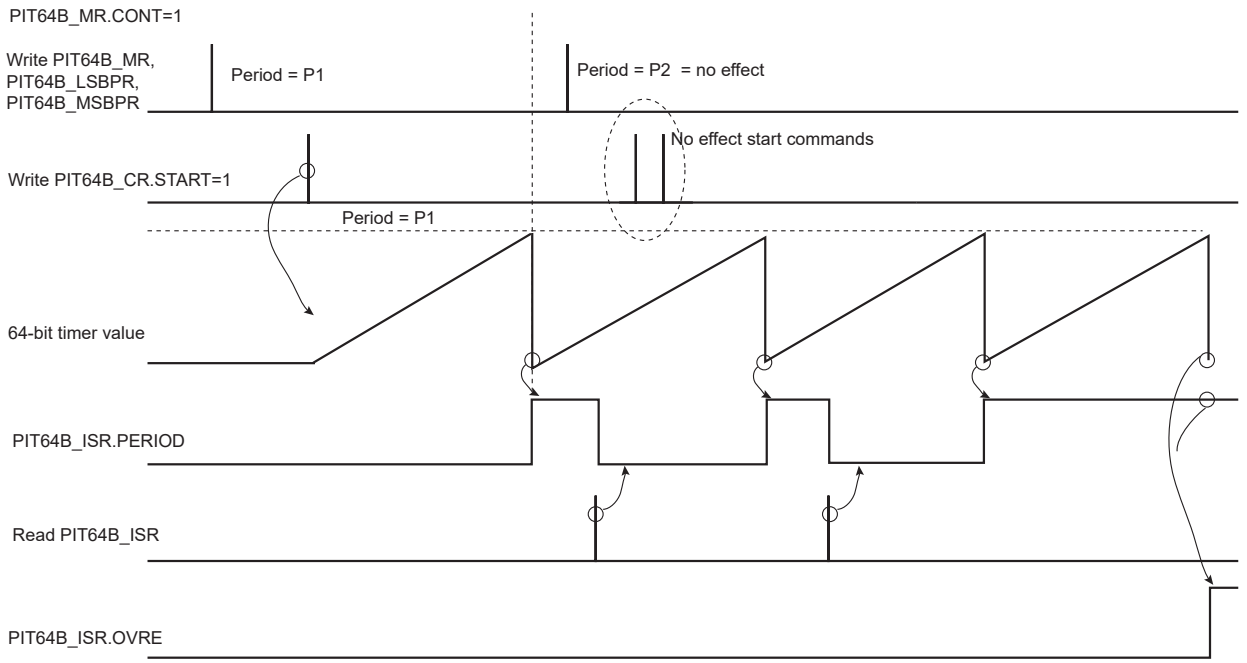
36.5.3. Continuous Period Mode

When the PIT64B_MR.CONT bit is written to 1, the PIT64B continuously produces timer events. The timer is started as soon as the PIT64B_CR.START bit is written to 1. The period is defined by configuring the PIT64B_LSBPR.LSBPERIOD field and PIT64B_MSBPR.MSBPERIOD field. When the START command is issued, the 64-bit timer loads 0 and increments up to LSBPERIOD and

© 2026 Microchip Technology Inc. and its subsidiaries

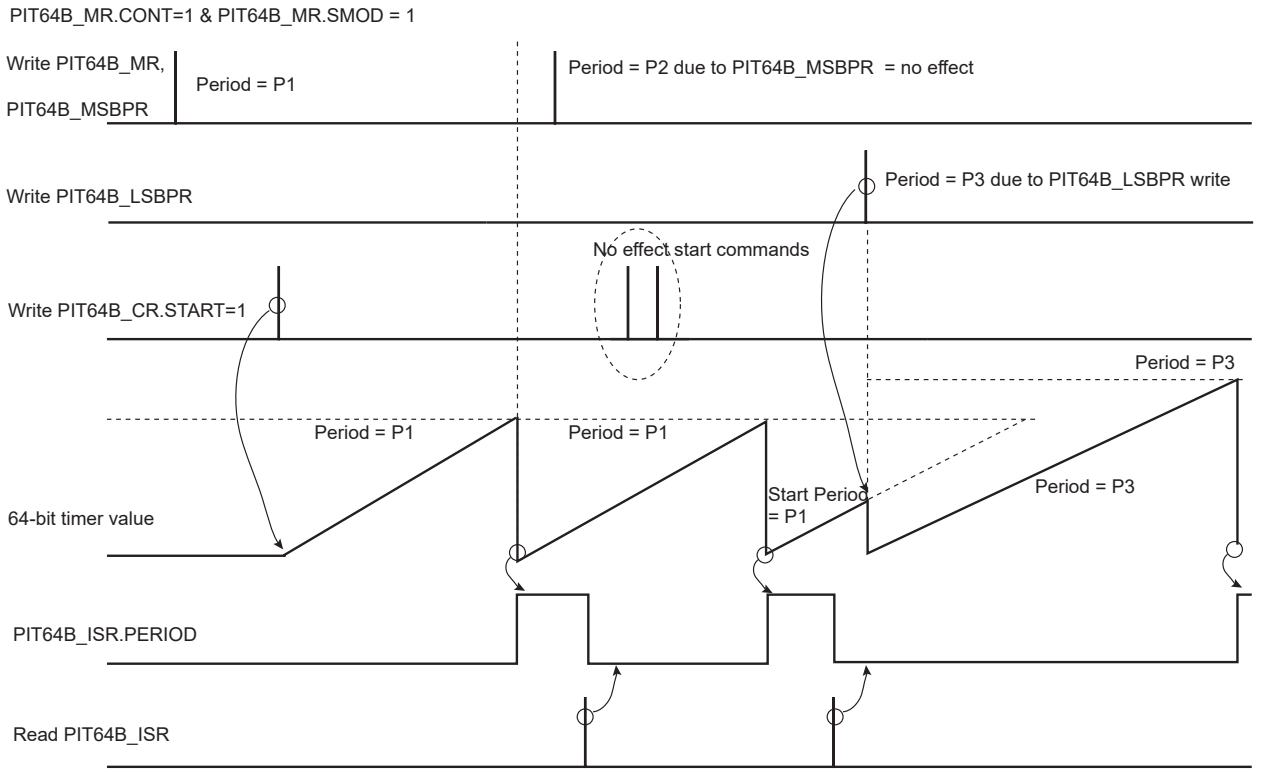
MSBPERIOD field value minus 1, then automatically reloads 0 anc restarts a new counting period until bit PIT64B_CR.SWRST is written to 1.



When the timer reaches its maximum value, the flag PIT64B_ISR.PERIOD is set. PIT64B_ISR.PERIOD is cleared when reading PIT64B_ISR. If a new period elapses and the PIT64B_ISR.PERIOD is 1, the PIT64B_ISR.OVRE flag is set to indicate a potential latency at system level

After the START command has been issued, any new values written in PIT64B_MR, PIT64B_LSBPR or PIT64B_MSBPR have no effect on the current period if bit PIT64B_MR.SMOD=0 (see Figure 36.4). A software reset must be issued before configuring new values in PIT64B_LSBPR and PIT64B_MSBPR if bit PIT64B_MR.SMOD=0.

If PIT64B_MR.SMOD=1 a start can be also performed as soon as PIT64B_LSBPR is written, thus a modification of the period can be performed on-the-fly with a single write operation if the period requires no more than 32 bits. When writing a 64-bit value, the 32-bit MSB part must be configured first followed by a 32-bit LSB part (see Figure 36.5). When configuring a value lower or equal to 32 bits after processing a period defined on 64 bits, first PIT64B_MSBPR must be written to 0, and then the 32-bit LSB must be written into PIT64B_LSBPR.



If PIT64B_CR.SWRST is written to 1, the current period is immediately stopped.

Figure 36.4. Waveform in Continuous Period Mode if bit PIT64B_MR.SMOD=0

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 36.5. Waveform in Continuous Period Mode if bit PIT64B_MR.SMOD=1

36.5.4. Security and Safety Analysis and Reports

Several types of checks are performed when the PIT64B is running.

The peripheral clock of the PIT64B is monitored by a specific circuitry to detect abnormal waveforms on the internal clock that may affect the behavior of the PIT64B. Corruption on the triggering edge of the clock or a pulse with a minimum duration may be identified. If the CGD flag is set in the Write Protection Status register (PIT64B_WPSR), an abnormal condition occurred on the peripheral clock. This flag is not set under normal operating conditions.

The internal timer sequence of the PIT64B is also monitored and if an abnormal state is detected, the flag PIT64B_WPSR.SEQE is set. This flag is not set under normal operating conditions.

The software accesses to the PIT64B are monitored and if an incorrect access is performed, the flag PIT64B_WPSR.SWE is set. The type of incorrect/abnormal software access is reported in the PIT64B_WPSR.SWETYP field (see PIT64B Write Protection Status Register for details). For example, writing PIT64B_MR, PIT64B_LSBPR (if PIT64B_MR.SMOD=0), PIT64B_MSBPR (if PIT64B_MR.SMOD=0) when the timer is running (after a START command has been issued) is an error. PIT64B_WPSR.ECLASS is an indicator reporting the criticality of the SWETYP report.

The flags CGD, SEQE, SWE and WPVS are automatically cleared when PIT64B_WPSR is read.

If one of these flags is set, the PIT64B_ISR.SECE flag is set and can trigger an interrupt if the SECE bit, in the Interrupt Mask register (PIT64B_IMR), is ‘1’. SECE is cleared by reading PIT64B_ISR.

36.5.5. Register Write Protection

To prevent any single software error from corrupting PIT64B behavior, certain registers in the address space can be write-protected by setting the WPEN (Write Protection Enable), WPITEN (Write Protection Interrupt Enable), and/or WPCREN (Write Protection Control Enable) bits in the PIT64B Write Protection Mode Register (PIT64B_WPMR).

© 2026 Microchip Technology Inc. and its subsidiaries

If a write access to a write-protected register is detected, the WPVS (Write Protection Violation Status) flag in the PIT64B Write Protection Status Register (PIT64B_WPSR) is set and the WPVSRC (Write Protection Violation Source) field indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading PIT64B_WPSR.

The following registers can be write-protected when WPEN is set in PIT64B_WPMR:

- PIT64B Mode Register
- PIT64B LSB Period Register
- PIT64B MSB Period Register

Note: PIT64B LSB Period Register and PIT64B MSB Period Register are not write-protected if PIT64B_MR.SMOD=1.

The following registers can be write-protected when WPITEN is set in PIT64B_WPMR:

- PIT64B Interrupt Enable Register
- PIT64B Interrupt Disable Register

The following register can be write-protected when WPCREN is set in PIT64B_WPMR:

- PIT64B Control Register

36.6.1. PIT64B Control Register

Name: PIT64B_CR
Offset: 0x00
Reset: –
Property: Write-only

This register can only be written if the WPCREN bit is cleared in the PIT64B Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								W
Reset								–

Bit	7	6	5	4	3	2	1	0
Access								W
Reset								–

Bit 8 – SWRST Software Reset

Value	Description
0	No effect.
1	Performs a software reset, clears the configuration and stops any timer period in progress.

Bit 0 – START Start Timer

Value	Description
0	No effect.
1	The timer counter is started for 1 or more periods. If the START command is applied during a non-elapsed timer period, there is no effect. Thus, in Continuous mode, the SWRST command is the only command to stop the PIT64B. If PIT64B_MR.SMOD=1 a start is also performed as soon as PIT64B_LSBPR is written (see Single Period Mode and Continuous Period Mode).

© 2026 Microchip Technology Inc. and its subsidiaries

36.6.2. PIT64B Mode Register

Name: PIT64B_MR
Offset: 0x04
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PIT64B Write Protection Mode Register.

When the timer is running, writing a value to this register has no effect. The value written is this register is loaded anytime before a START command is issued.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
					PRESCALER[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
				SMOD	SGCLK			CONT
Access				R/W	R/W			R/W
Reset				0	0			0

Bits 11:8 – PRESCALER[3:0] Prescaler Period

Value	Description
0	A prescaler divider of 1 is used.
1–15	The 64-bit timer is incremented at each (PRESCALER+1)x selected period (see SGCLK).

Bit 4 – SMOD Start Mode

Value	Description
0	Writing PIT64B_LSBPR does not start the timer period.
1	Writing PIT64B_LSBPR starts the timer period.

Bit 3 – SGCLK Generic Clock Selection Enable

If GCLK is asynchronous to the peripheral clock, a jitter of 1 peripheral clock period is created on the periodic interval event when Continuous mode is selected.

Value	Description
0	The prescaler is triggered at each rising edge of “Peripheral clock” and the timer is triggered.
1	GCLK clock is selected as clock source of the 8-bit prescaler.

Bit 0 – CONT Continuous Mode

Value	Description
0	A single period interrupt is generated from a START command.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	Continuous periodic interrupts are generated after a single START command.

© 2026 Microchip Technology Inc. and its subsidiaries

36.6.3. PIT64B LSB Period Register

Name: PIT64B_LSBPR
Offset: 0x08
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PIT64B Write Protection Mode Register or if PIT64B_MR.SMOD=1.

When the timer is running, if PIT64B_MR.SMOD=0, writing a value to this register has no effect. The value written is this register must be loaded anytime before a START command is issued if PIT64B_MR.SMOD=0. If PIT64B_MR.SMOD=1, a write access to this register restarts a timer period.

Bit	31	30	29	28	27	26	25	24
	LSBPERIOD[31:24]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:0 – LSBPERIOD[31:0] 32 LSB of the Timer Period
This field defines the 32 LSB of the timer period. The timer period is defined by selected clock x {MSBPERIOD,LSBPERIOD}.

© 2026 Microchip Technology Inc. and its subsidiaries

36.6.4. PIT64B MSB Period Register

Name: PIT64B_MSBPR
Offset: 0x0C
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PIT64B Write Protection Mode Register.

When the timer is running, if PIT64B_MR.SMOD=0, writing a value to this register has no effect. The value written is this register must be loaded anytime before a START command is issued if PIT64B_MR.SMOD=0.

Bit	31	30	29	28	27	26	25	24
	MSBPERIOD[31:24]

Reset	0	0	0	0	0	0	0	0

Bits 31:0 – MSBPERIOD[31:0] 32 MSB of the Timer Period
This field defines the 32 MSB of the timer period. The timer period is defined by selected clock x {MSBPERIOD,LSBPERIOD}.

© 2026 Microchip Technology Inc. and its subsidiaries

36.6.5. PIT64B Interrupt Enable Register

Name: PIT64B_IER
Offset: 0x10
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the PIT64B Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect

1: Enables the corresponding interrupt

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

36.6.6. PIT64B Interrupt Disable Register

Name: PIT64B_IDR
Offset: 0x14
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the PIT64B Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect

1: Disables the corresponding interrupt

Bit	31	30	29	28	27	26	25	24
Access

Bit	7	6	5	4	3	2	1	0
				SECE			OVRE	PERIOD
Access				R			R	R
Reset				0			0	0

Bit 4 – SECE Safety/Security Report (cleared on read)

Value	Description
0	There has been no security report in PIT64B_WPSR since the last read of PIT64B_ISR.
1	One security flag has been set in PIT64B_WPSR since the last read of PIT64B_ISR.

Bit 1 – OVRE Overrun Error (cleared on read)

Value	Description
0	No multiple rollovers occurred since the last read of PIT64B_ISR.
1	More than 1 rollover occurred since the last read of PIT64B_ISR.

Bit 0 – PERIOD Elapsed Timer Period Status Flag (cleared on read)

Value	Description
0	No timer rollover occurred since the last read of PIT64B_ISR.
1	A timer rollover occurred since the last read of PIT64B_ISR.

© 2026 Microchip Technology Inc. and its subsidiaries

36.6.9. PIT64B Timer LSB Register

Name: PIT64B_TLSBR
Offset: 0x20
Reset: 0x00000000
Property: Read-only

This field returns the 32 LSB of the current timer value.

© 2026 Microchip Technology Inc. and its subsidiaries

36.6.10. PIT64B Timer MSB Register

Name: PIT64B_TMSBR
Offset: 0x24
Reset: 0x00000000
Property: Read-only

When operating with a timer value greater than 32 bits (PIT64B_MSBPR.MSBPERIOD > 0), the PIT64B_TLSBR must be read first, followed by the read of PIT64B_TMSBR. This sequence generates an atomic read of the 64-bit timer value whatever the lapse of time between the accesses. When operating with a timer value up to 32 bits (PIT64B_MSBPR.MSBPERIOD=0), reading PIT64B_TMSBR is not required.

Bit	31	30	29	28	27	26	25	24

Access				R/W		R/W	R/W	R/W
Reset				0		0	0	0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x504954	PASSWD	Writing any other value in this field aborts the write operation of the WPCREN, WPITEN and WPEN bits. Always reads as 0.

Bit 4 – FIRSTE First Error Report Enable

Value	Description
0	The last write protection violation source is reported in PIT64B_WPSR.WPVSRC and the last software control error type is reported in PIT64B_WPSR.SWETYP. The PIT64B_ISR.SECE flag is set at the first error occurring within a series.
1	Only the first write protection violation source is reported in PIT64B_WPSR.WPVSRC and only the first software control error type is reported in PIT64B_WPSR.SWETYP. The PIT64B_ISR.SECE flag is set at the first error occurring within a series.

Bit 2 – WPCREN Write Protection Control Enable

Value	Description
0	Disables the write protection on control register if WPKEY corresponds to 0x504954 (“PIT” in ASCII).
1	Enables the write protection on control register if WPKEY corresponds to 0x504954 (“PIT” in ASCII).

Bit 1 – WPITEN Write Protection Interruption Enable

Value	Description
0	Disables the write protection on interrupt registers if WPKEY corresponds to 0x504954 (“PIT” in ASCII).
1	Enables the write protection on interrupt registers if WPKEY corresponds to 0x504954 (“PIT” in ASCII).

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 0 – WPEN Write Protection Enable

See Register Write Protection for the list of registers that can be protected.

Value	Description
0	Disables the write protection if WPKEY corresponds to 0x504954 (“PIT” in ASCII).
1	Enables the write protection if WPKEY corresponds to 0x504954 (“PIT” in ASCII).

Access					R	R	R	R
Reset					0	0	0	0

Bit 31 – ECLASS Software Error Class (cleared on read)
0 (WARNING): An abnormal access that does not affect system functionality.
1 (ERROR): A write access is performed into PIT64B_MR, PIT64B_LSBR, PIT64B_MSBR while the PIT64B is running.

Bits 25:24 – SWETYP[1:0] Software Error Type (cleared on read)

Value	Name	Description
0	READ_WO	A write-only register has been read (warning).
1	WRITE_RO	A write access has been performed on a read-only register (warning).
2	UNDEF_RW	Access to an undefined address (warning).
3	WEIRD_ACTION	A write access is performed into PIT64B_MR, PIT64B_LSBR, PIT64B_MSBR while the PIT64B is running (abnormal).

Bits 23:8 – WPVSRC[15:0] Write Protection Violation Source
When WPVS=1, WPVSRC indicates the register address offset at which a write access has been attempted.
When WPVS=0 and SWE=1, WPVSRC reports the address of the incorrect software access. As soon as WPVS=1, WPVSRC returns the address of the write-protected violation.

Bit 3 – SWE Software Control Error (cleared on read)

Value	Description
0	No software error has occurred since the last read of PIT64B_WPSR.
1	A software error has occurred since the last read of PIT64B_WPSR. The field SWETYP details the type of software error; the associated incorrect software access is reported in the field WPVSRC (if WPVS=0).

Bit 2 – SEQE Internal Sequencer Error (cleared on read)

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	No peripheral internal sequencer error has occurred since the last read of PIT64B_WPSR.
1	A peripheral internal sequencer error has occurred since the last read of PIT64B_WPSR. This flag can only be set under abnormal operating conditions.

Bit 1 – CGD Clock Glitch Detected (cleared on read)

Value	Description
0	The clock monitoring circuitry has not been corrupted since the last read of PIT64B_WPSR. Under normal operating conditions, this bit is always cleared.
1	The clock monitoring circuitry has been corrupted since the last read of PIT64B_WPSR. This flag can only be set in case of abnormal clock signal waveform (glitch).

Bit 0 – WPVS Write Protection Violation Status (cleared on read)

Value	Description
0	No write protection violation has occurred since the last read of the PIT64B_WPSR.
1	A write protection violation has occurred since the last read of the PIT64B_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSRC.

37. Debug Unit (DBGU)

37.1. Description

The Debug Unit (DBGU) provides a single entry point from the processor for access to all the debug capabilities of the product.

The DBGU features a two-pin UART that can be used for communication and trace purposes and offers an ideal medium for in-situ programming solutions.

Moreover, the association with a DMA controller permits packet handling for these tasks with processor time reduced to a minimum.

The DBGU also makes the Debug Communication Channel (DCC) signals provided by the In-circuit Emulator of the Arm processor visible to the software. These signals indicate the status of the DCC read and write registers and generate an interrupt to the Arm processor, making possible the handling of the DCC under interrupt control.

Chip identifier registers permit recognition of the device and its revision. These registers indicate the sizes and types of the on-chip memories, as well as the set of embedded peripherals.

A Force NTRST capability enables the software to decide whether to prevent access to the system via the In-circuit Emulator (ICE). This disables system access through the processor's ICE, thus protecting the code stored in ROM by asserting the NTRST line of the processor's ICE.

37.2. Embedded Characteristics

- ICE Access Prevention
- Debug Communication Channel (DCC) Support
- Chip ID Registers
- Two-pin UART
  - Independent receiver and transmitter with a common programmable baud rate generator
  - Baud rate can be driven by processor-independent generic source clock
  - Even, odd, mark or space parity generation
  - Parity, framing and overrun error detection
  - Automatic Echo, Local loopback and Remote Loopback Channel modes
  - Digital filter on receive line
  - Interrupt generation
  - Support for two DMA channels with connection to receiver and transmitter
  - Receiver timeout
  - Register write protection

37.3. Block Diagram

Figure 37.1. DBGU Block Diagram

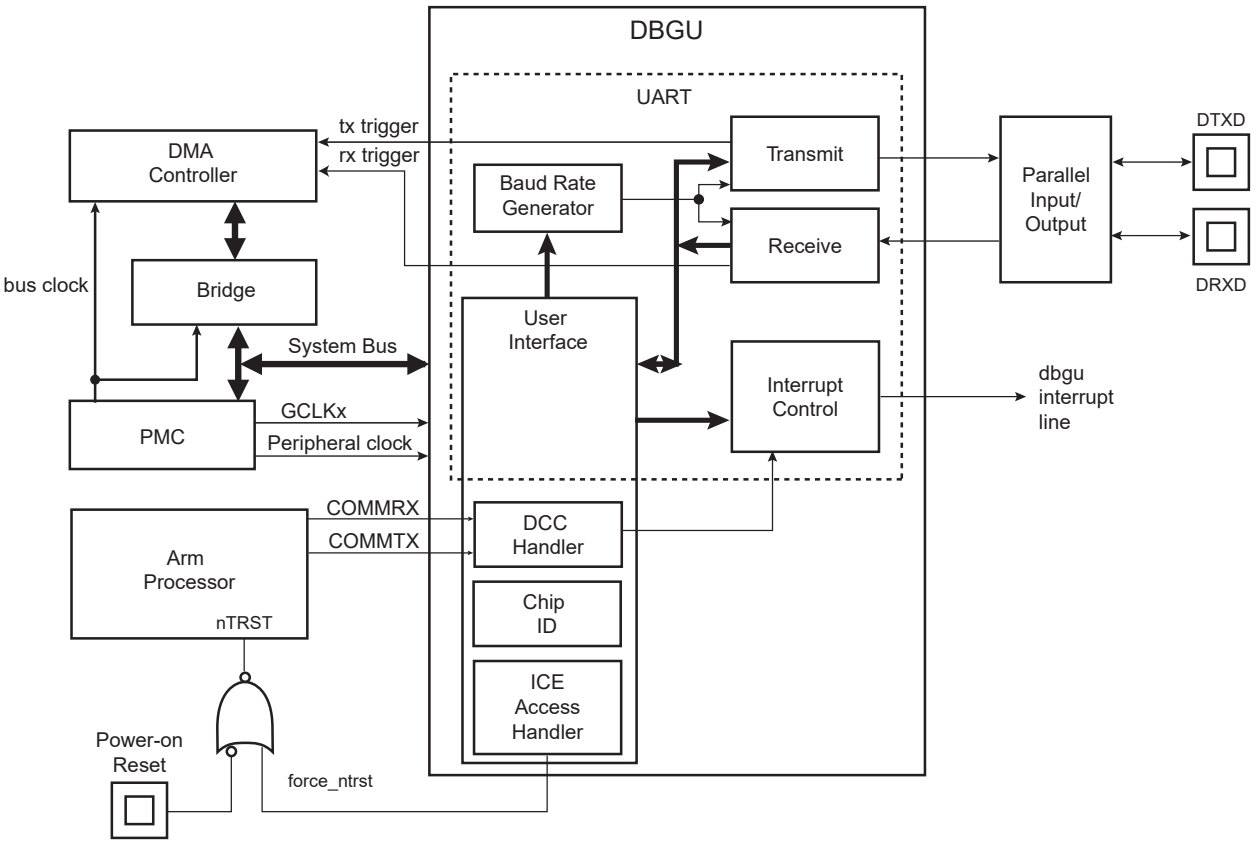

Table 37.1. DBGU Pin Description

Pin Name	Description	Type
DRXD	DBGU Receive Data	Input
DTXD	DBGU Transmit Data	Output

37.4. Product Dependencies

37.4.1. I/O Lines

The DBGU pins are multiplexed with PIO lines. The user must first configure the corresponding PIO Controller to enable I/O line operations of the DBGU.

37.4.2. Power Management

The DBGU clock can be controlled through the Power Management Controller (PMC). In this case, the user must first configure the PMC to enable the DBGU clock.

37.4.3. Interrupt Sources

The DBGU interrupt line is connected to one of the interrupt sources of the Interrupt Controller. Interrupt handling requires programming of the Interrupt Controller before configuring the DBGU.

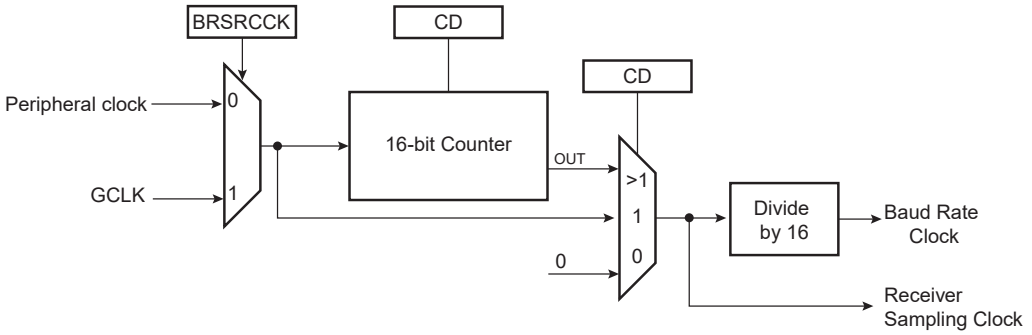
37.5. Functional Description

The DBGU operates in Asynchronous mode only and supports only 8-bit character handling (with parity). It has no clock pin.

© 2026 Microchip Technology Inc. and its subsidiaries

The DBGU is made up of a receiver and a transmitter that operate independently, and a common baud rate generator. Receiver timeout and transmitter time guard are not implemented. However, all the implemented features are compatible with those of a standard USART.

37.5.1. Baud Rate Generator



The baud rate generator provides the bit period clock named baud rate clock to both the receiver and the transmitter.

The baud rate clock is the peripheral clock divided by 16 times the clock divisor (CD) value written in the Baud Rate Generator register (DBGU_BRGR). If DBGU_BRGR is set to 0, the baud rate clock is disabled and the DBGU remains inactive. The maximum allowable baud rate is peripheral clock or GCLK divided by 16. The minimum allowable baud rate is peripheral clock divided by (16 x 65536). The clock source driving the baud rate generator (peripheral clock or GCLK) can be selected by writing the bit BRSRCCK in DBGU_MR.

If GCLK is selected, the baud rate is independent of the processor/bus clock. Thus the processor clock can be changed while DBGU is enabled. The processor clock frequency changes must be performed only by programming the field PRES in PMC_MCKR (see PMC section). Other methods to modify the processor/bus clock frequency (PLL multiplier, etc.) are forbidden when DBGU is enabled.

The peripheral clock frequency must be at least three times higher than GCLK.

Figure 37.2. Baud Rate Generator

37.5.2. Receiver

37.5.2.1. Receiver Reset, Enable and Disable

After device reset, the DBGU receiver is disabled and must be enabled before being used. The receiver can be enabled by writing the Control register (DBGU_CR) with the bit RXEN at 1. At this command, the receiver starts looking for a start bit.

The programmer can disable the receiver by writing DBGU_CR with the bit RXDIS at 1. If the receiver is waiting for a start bit, it is immediately stopped. However, if the receiver has already detected a start bit and is receiving the data, it waits for the stop bit before actually stopping its operation.

The receiver can be put in reset state by writing DBGU_CR with the bit RSTRX at 1. In this case, the receiver immediately stops its current operations and is disabled, whatever its current state. If RSTRX is applied when data is being processed, this data is lost.

37.5.2.2. Start Detection and Data Sampling

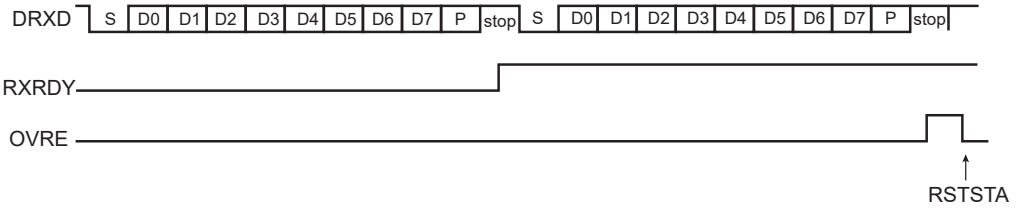
The DBGU only supports asynchronous operations, and this affects only its receiver. The DBGU receiver detects the start of a received character by sampling the DRXD signal until it detects a valid start bit. A low level (space) on DRXD is interpreted as a valid start bit if it is detected for more than seven cycles of the sampling clock, which is 16 times the baud rate. Hence, a space that is longer than 7/16 of the bit period is detected as a valid start bit. A space which is 7/16 of a bit period or shorter is ignored and the receiver continues to wait for a valid start bit.

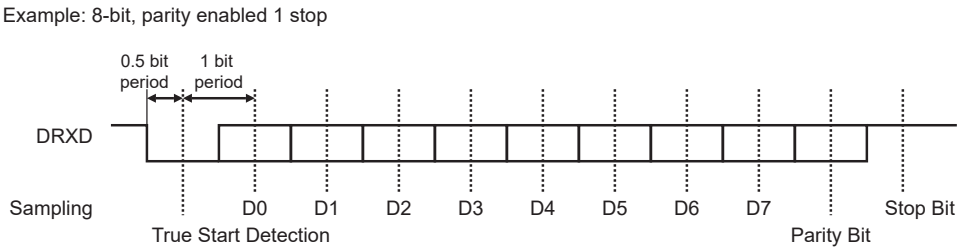
© 2026 Microchip Technology Inc. and its subsidiaries

When a valid start bit has been detected, the receiver samples the DRXD at the theoretical midpoint of each bit. It is assumed that each bit lasts 16 cycles of the sampling clock (1-bit period) so the bit sampling point is eight cycles (0.5-bit period) after the start of the bit. The first sampling point is therefore 24 cycles (1.5-bit periods) after detecting the falling edge of the start bit.

Each subsequent bit is sampled 16 cycles (1-bit period) after the previous one.

Figure 37.3. Start Bit Detection





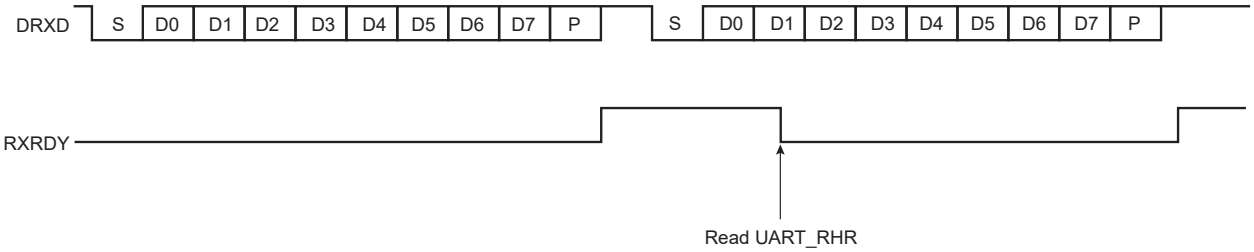


Figure 37.4. Character Reception

37.5.2.3.Receiver Ready

When a complete character is received, it is transferred to the Receive Holding register (DBGU_RHR) and the RXRDY status bit in the Status register (DBGU_SR) is set. The bit RXRDY is automatically cleared when DBGU_RHR is read.

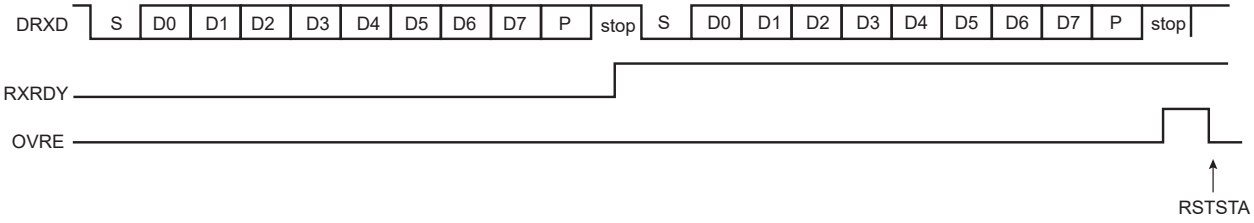

Figure 37.5. Receiver Ready

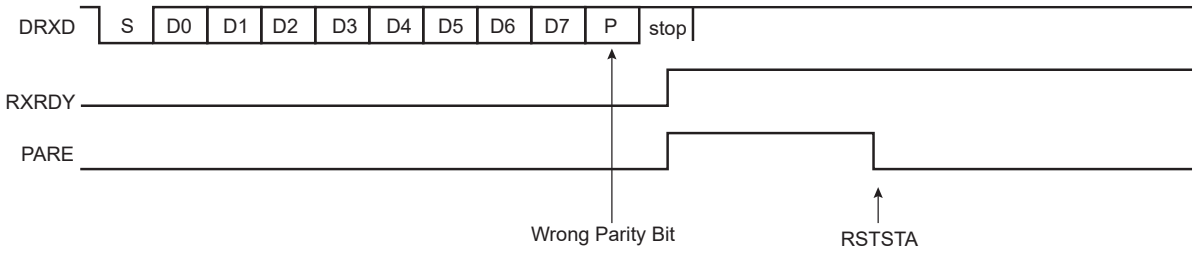
37.5.2.4.Receiver Overrun

The OVRE status bit in DBGU_SR is set if DBGU_RHR has not been read by the software (or the DMA Controller) since the last transfer, the RXRDY bit is still set and a new character is received. OVRE is cleared when the software writes a 1 to the bit RSTSTA (Reset Status) in DBGU_CR.

Figure 37.6. Receiver Overrun



© 2026 Microchip Technology Inc. and its subsidiaries

37.5.2.5. Parity Error

Each time a character is received, the receiver calculates the parity of the received data bits, in accordance with the field PAR in the Mode register (DBGU_MR). It then compares the result with the received parity bit. If different, the parity error bit PARE in DBGU_SR is set at the same time RXRDY is set. The parity bit is cleared when DBGU_CR is written with the bit RSTSTA (Reset Status) at 1. If a new character is received before the reset status command is written, the PARE bit remains at 1.

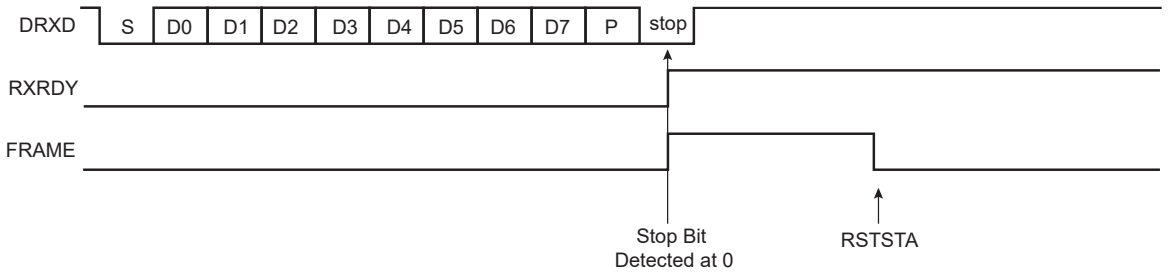


Figure 37.7. Parity Error

37.5.2.6. Receiver Framing Error

When a start bit is detected, it generates a character reception when all the data bits have been sampled. The stop bit is also sampled and when it is detected at 0, the FRAME (Framing Error) bit in DBGU_SR is set at the same time the RXRDY bit is set. The FRAME bit remains high until the Control register (DBGU_CR) is written with the bit RSTSTA at 1.

Figure 37.8. Receiver Framing Error

37.5.2.7. Receiver Digital Filter

The DBGU embeds a digital filter on the receive line. It is disabled by default and can be enabled by writing a logical 1 in the FILTER bit of DBGU_MR. When enabled, the receive line is sampled using the 16x bit clock and a three-sample filter (majority 2 over 3) determines the value of the line.

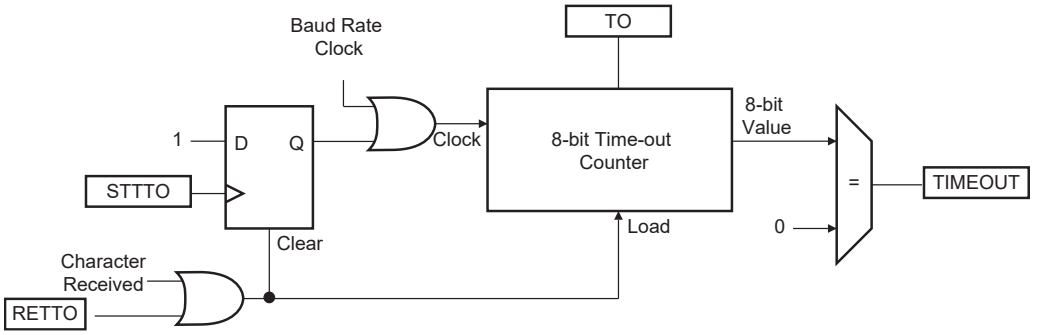
37.5.2.8. Receiver Timeout

The Receiver Timeout provides support in handling variable-length frames. This feature detects an idle condition on the DRXD line. When a timeout is detected, the bit TIMEOUT in DBGU_SR rises and can generate an interrupt, thus indicating to the driver an end of frame.

The timeout delay period (during which the receiver waits for a new character) is programmed in the TO field of the Receiver Timeout register (DBGU_RTOR). If the TO field is written to 0, the Receiver Timeout is disabled and no timeout is detected. The TIMEOUT bit remains at 0. Otherwise, the receiver loads an 8-bit counter with the value programmed in TO. This counter is decremented at each bit period and reloaded each time a new character is received. If the counter reaches 0, the TIMEOUT bit rises. Then, the user can either:

- stop the counter clock until a new character is received. This is performed by writing a one to the STTTO (Start timeout) bit in DBGU_CR. In this case, the idle state on DRXD before a new character is received does not provide a timeout. This prevents having to handle an interrupt before a character is received and allows waiting for the next idle state on DRXD after a frame is received, or

© 2026 Microchip Technology Inc. and its subsidiaries



- obtain an interrupt while no character is received. This is performed by writing a one to the RETTO (Reload and start timeout) bit in DBGU_CR. If RETTO is performed, the counter starts counting down immediately from the TO value. This enables generation of a periodic interrupt so that a user timeout can be handled, for example when no key is pressed on a keyboard.

If STTTO is performed, the counter clock is stopped until a first character is received. The idle state on DRXD before the start of the frame does not provide a timeout. This prevents having to obtain a periodic interrupt and enables a wait of the end of frame when the idle state on DRXD is detected.

If RETTO is performed, the counter starts counting down immediately from the TO value. This enables generation of a periodic interrupt so that a user timeout can be handled, for example when no key is pressed on a keyboard.

The following figure shows the block diagram of the Receiver Timeout feature.

Figure 37.9. Receiver Timeout Block Diagram

The following table shows the maximum timeout period for some standard baud rates.

Table 37.2. Maximum Timeout Period

Baud Rate (bit/s)	Bit Time (µs)	Timeout (µs)
600	1,667	425,085
1,200	833	212,415
2,400	417	106,335
4,800	208	53,040
9,600	104	26,520
14,400	69	17,595
19,200	52	13,260
28,800	35	8,925
38,400	26	6,630
56,000	18	4,590
57,600	17	4,335
200,000	5	1,275

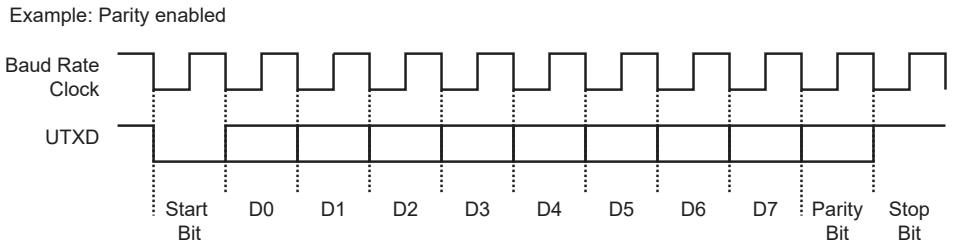
37.5.3. Transmitter

37.5.3.1. Transmitter Reset, Enable and Disable

After device reset, the DBGU transmitter is disabled and must be enabled before being used. The transmitter is enabled by writing DBGU_CR with the bit TXEN at 1. From this command, the transmitter waits for a character to be written in the Transmit Holding register (DBGU_THR) before actually starting the transmission.

The programmer can disable the transmitter by writing DBGU_CR with the bit TXDIS at 1. If the transmitter is not operating, it is immediately stopped. However, if a character is being processed

© 2026 Microchip Technology Inc. and its subsidiaries



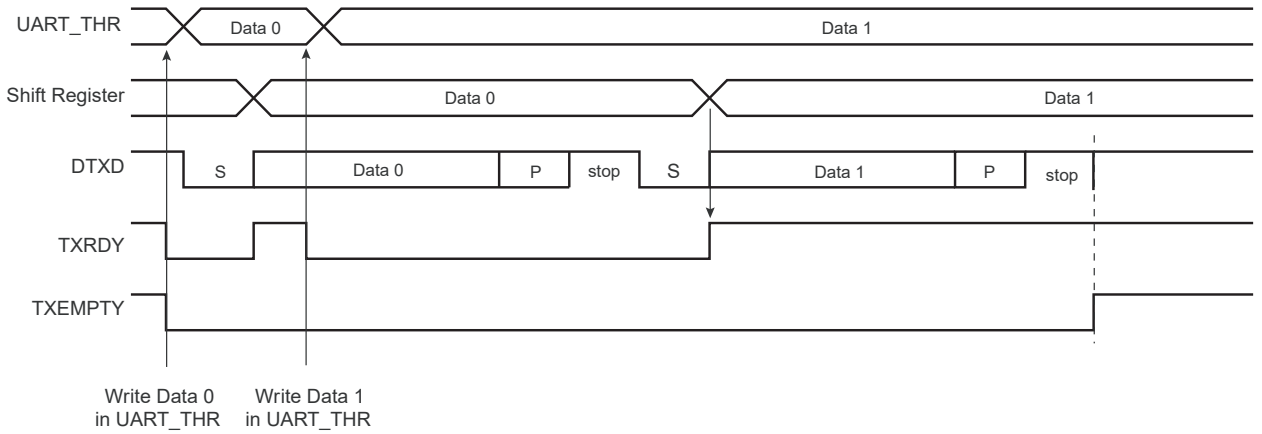
into the internal shift register and/or a character has been written in the DBGU_THR, the characters are completed before the transmitter is actually stopped.

The programmer can also put the transmitter in its reset state by writing the DBGU_CR with the bit RSTTX at 1. This immediately stops the transmitter, whether or not it is processing characters.

37.5.3.2. Transmit Format

The DBGU transmitter drives the pin DTXD at the baud rate clock speed. The line is driven depending on the format defined in DBGU_MR and the data stored in the internal shift register. One start bit at level 0, then the 8 data bits, from the lowest to the highest bit, one optional parity bit and one stop bit at 1 are consecutively shifted out as shown in the following figure. The field PARE in DBGU_MR defines whether or not a parity bit is shifted out. When a parity bit is enabled, it can be selected between an odd parity, an even parity, or a fixed space or mark bit.

Figure 37.10. Character Transmission



37.5.3.3. Transmitter Control

When the transmitter is enabled, the bit TXRDY (Transmitter Ready) is set in DBGU_SR. The transmission starts when the programmer writes in the DBGU_THR, and after the written character is transferred from DBGU_THR to the internal shift register. The TXRDY bit remains high until a second character is written in DBGU_THR. As soon as the first character is completed, the last character written in DBGU_THR is transferred into the internal shift register and TXRDY rises again, showing that the holding register is empty.

When both the internal shift register and DBGU_THR are empty, i.e., all the characters written in DBGU_THR have been processed, the TXEMPTY bit rises after the last stop bit has been completed.

Figure 37.11. Transmitter Control

37.5.4. DMA Support

Both the receiver and the transmitter of the DBGU are connected to a DMA Controller (DMAC) channel.

© 2026 Microchip Technology Inc. and its subsidiaries

The DMA Controller channels are programmed via registers that are mapped within the DMAC user interface.

37.5.5. Register Write Protection

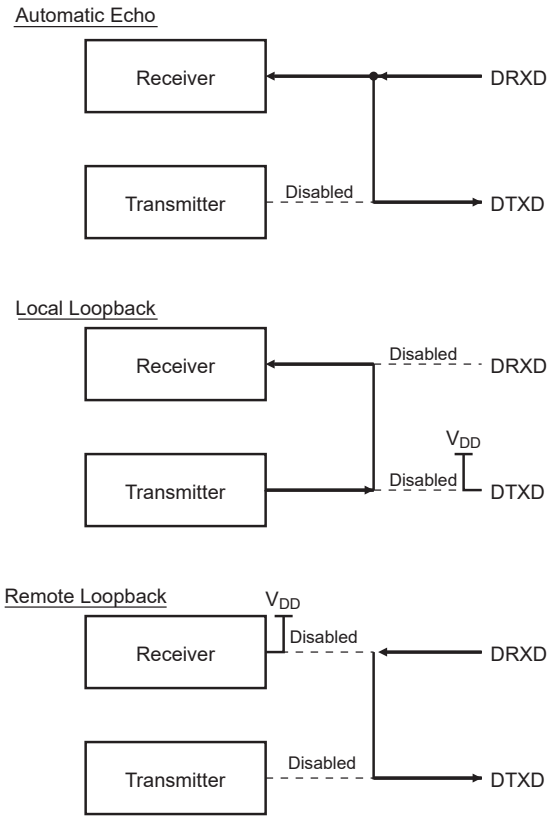
To prevent any single software error from corrupting DBGU behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the DBGU Write Protection Mode Register.

The following registers can be write-protected:

- DBGU Mode Register
- DBGU Baud Rate Generator Register
- DBGU Receiver Timeout Register
- Debug Unit Force NTRST Register

37.5.6. Test Modes

The DBGU supports three test modes. These modes of operation are programmed by using the CHMODE field in DBGU_MR.



The Automatic Echo mode allows a bit-by-bit retransmission. When a bit is received on the DRXD line, it is sent to the DTXD line. The transmitter operates normally, but has no effect on the DTXD line.

The Local loopback mode allows the transmitted characters to be received. DTXD and DRXD pins are not used and the output of the transmitter is internally connected to the input of the receiver. The DRXD pin level has no effect and the DTXD line is held high, as in idle state.

The Remote loopback mode directly connects the DRXD pin to the DTXD line. The transmitter and the receiver are disabled and have no effect. This mode allows a bit-by-bit retransmission.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 37.12. Test Modes

37.5.7. Debug Communication Channel Support

The DBGU handles the COMMRX and COMMTX signals that come from the Debug Communication Channel of the Arm processor and are driven by the In-circuit Emulator.

The Debug Communication Channel contains two registers that are accessible through the ICE Breaker on the JTAG side and through the coprocessor 0 on the Arm processor side.

As a reminder, the following instructions are used to read and write the Debug Communication Channel:

```
MRC p14, 0, Rd, c1, c0, 0
```

Returns the debug communication data read register into Rd.

```
MCR p14, 0, Rd, c1, c0, 0
```

Writes the value in Rd to the debug communication data write register.

The COMMRX and COMMTX bits which indicate, respectively, that the read register has been written by the debugger but not yet read by the processor, and that the write register has been written by the processor and not yet read by the debugger, are wired on the two highest bits of DBGU_SR. These bits can generate an interrupt. This feature can be used to handle under interrupt a debug link between a debug monitor running on the target system and a debugger.

37.5.8. Chip Identifier

The DBGU features two chip identifier registers, DBGU Chip ID register (DBGU_CIDR) and DBGU Extension ID register (DBGU_EXID). Both registers contain a hard-wired value that is read-only.

© 2026 Microchip Technology Inc. and its subsidiaries

Table 37.3. DBGU_CIDR and DBGU_EXID Reset Values

Device Name	DBGU_CIDR	DBGU_EXID
SAM9X70	0x8975003X	0x00000080
		0x000000C4 (SL1)
		0x000000C5 (SL2)
		0x000000C6 (SL3)
SAM9X72		0x00000082
		0x000000D8 (SL1)
		0x000000D9 (SL2)
		0x000000DA (SL3)
SAM9X75		0x00000085
		0x000000DC (SL1)
		0x000000DD (SL2)
		0x000000DE (SL3)

The first register (DBGU_CIDR) contains the following fields:

- EXT: shows the use of the extension identifier register
- ID: product ID value
- VERSION: revision of the device

The second register (DBGU_EXID) is device-dependent and is read as 0 if DBGU_CIDR.EXT is 0.

37.5.9. ICE Access Prevention

The DBGU allows blockage of access to the system through the Arm processor's ICE interface. This feature is implemented via the Force NTRST register (DBGU_FNR), that allows assertion of the NTRST signal of the ICE interface. Writing the bit FNTRST (Force NTRST) to 1 in this register prevents any activity on the TAP controller.

Notes:

1. During ROM code execution, this bit is set (JTAG access is disabled).
2. This bit has no more effect once the JTAG access is disabled in the OTPC.

37.6.1. DBGU Control Register

Name: DBGU_CR
Offset: 0x0000
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
					STTTO	RETTO		RSTSTA
Access					W	W		W
Reset					–	–		–

Bit	7	6	5	4	3	2	1	0
	TXDIS	TXEN	RXDIS	RXEN	RSTTX	RSTRX		
Access	W	W	W	W	W	W		
Reset	–	–	–	–	–	–		

Bit 11 – STTTO Start Timeout

Value	Description
0	No effect.
1	Starts waiting for a character before clocking the timeout counter. Resets status bit DBGU_SR.TIMEOUT.

Bit 10 – RETTO Rearm Timeout

Value	Description
0	No effect.
1	Restarts timeout.

Bit 8 – RSTSTA Reset Status

Value	Description
0	No effect.
1	Resets the status bits PARE, FRAME and OVRE in DBGU_SR.

Bit 7 – TXDIS Transmitter Disable

Value	Description
0	No effect.
1	The transmitter is disabled. If a character is being processed and a character has been written in DBGU_THR and RSTTX is not set, both characters are completed before the transmitter is stopped.

Bit 6 – TXEN Transmitter Enable

Value	Description
0	No effect.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	The transmitter is enabled if TXDIS is 0.

Bit 5 – RXDIS Receiver Disable

Value	Description
0	No effect.
1	The receiver is disabled. If a character is being processed and RSTRX is not set, the character is completed before the receiver is stopped.

Bit 4 – RXEN Receiver Enable

Value	Description
0	No effect.
1	The receiver is enabled if RXDIS is 0.

Bit 3 – RSTTX Reset Transmitter

Value	Description
0	No effect.
1	The transmitter logic is reset and disabled. If a character is being transmitted, the transmission is aborted.

Bit 2 – RSTRX Reset Receiver

Value	Description
0	No effect.
1	The receiver logic is reset and disabled. If a character is being received, the reception is aborted.

37.6.2. DBGU Mode Register

Name: DBGU_MR
Offset: 0x0004
Reset: 0x0000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	CHMODE[1:0]			BRSRCCK	PAR[2:0]			
Access	R/W	R/W		R/W	R/W	R/W	R/W	
Reset	0	0		0	0	0	0	

Bit	7	6	5	4	3	2	1	0
				FILTER				
Access				R/W				
Reset				0				

Bits 15:14 – CHMODE[1:0] Channel Mode

Value	Name	Description
0	NORMAL	Normal mode
1	AUTOMATIC	Automatic echo
2	LOCAL_LOOPBACK	Local loopback
3	REMOTE_LOOPBACK	Remote loopback

Bit 12 – BRSRCCK Baud Rate Source Clock
0 (PERIPH_CLK): The baud rate is driven by the peripheral clock
1 (GCLK): The baud rate is driven by a PMC-programmable clock GCLK (see section Power Management Controller (PMC)).

Bits 11:9 – PAR[2:0] Parity Type

Value	Name	Description
0	EVEN	Even Parity
1	ODD	Odd Parity
2	SPACE	Space: parity forced to 0
3	MARK	Mark: parity forced to 1
4	NO	No parity

Bit 4 – FILTER Receiver Digital Filter
0 (DISABLED): DBGU does not filter the receive line.
1 (ENABLED): DBGU filters the receive line using a three-sample filter (16x-bit clock) (2 over 3 majority).

37.6.3. DBGU Interrupt Enable Register

Name: DBGU_IER
Offset: 0x0008
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
	COMMRX	COMMTX						
Access	W	W						
Reset	–	–						

Bit	23	22	21	20	19	18	17	16

Reset							–	–

Bit	7	6	5	4	3	2	1	0
	PARE	FRAME	OVRE				TXRDY	RXRDY
Access	W	W	W				W	W
Reset	–	–	–				–	–

Bit 31 – COMMRX Enable COMMRX (from Arm) Interrupt

Bit 30 – COMMTX Enable COMMTX (from Arm) Interrupt

Bit 9 – TXEMPTY Enable TXEMPTY Interrupt

Bit 8 – TIMEOUT Enable Timeout Interrupt

Bit 7 – PARE Enable Parity Error Interrupt

Bit 6 – FRAME Enable Framing Error Interrupt

Bit 5 – OVRE Enable Overrun Error Interrupt

Bit 1 – TXRDY Enable TXRDY Interrupt

Bit 0 – RXRDY Enable RXRDY Interrupt

37.6.4. DBGU Interrupt Disable Register

Name: DBGU_IDR
Offset: 0x000C
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
	COMMRX	COMMTX						
Access	W	W						
Reset	–	–						

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
							TXEMPTY	TIMEOUT
Access							W	W
Reset							–	–

Bit	7	6	5	4	3	2	1	0
	PARE	FRAME	OVRE				TXRDY	RXRDY
Access	W	W	W				W	W
Reset	–	–	–				–	–

Bit 31 – COMMRX Disable COMMRX (from Arm) Interrupt

Bit 30 – COMMTX Disable COMMTX (from Arm) Interrupt

Bit 9 – TXEMPTY Disable TXEMPTY Interrupt

Bit 8 – TIMEOUT Disable Timeout Interrupt

Bit 7 – PARE Disable Parity Error Interrupt

Bit 6 – FRAME Disable Framing Error Interrupt

Bit 5 – OVRE Disable Overrun Error Interrupt

Bit 1 – TXRDY Disable TXRDY Interrupt

Bit 0 – RXRDY Disable RXRDY Interrupt

© 2026 Microchip Technology Inc. and its subsidiaries

37.6.5. DBGU Interrupt Mask Register

Name: DBGU_IMR
Offset: 0x0010
Reset: 0x0000000
Property: Read-only

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is disabled.

1: The corresponding interrupt is enabled.

Bit	31	30	29	28	27	26	25	24
	COMMRX	COMMTX						
Access	R	R						
Reset	0	0						

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
							TXEMPTY	TIMEOUT
Access							R	R
Reset							0	0

Bit	7	6	5	4	3	2	1	0
	PARE	FRAME	OVRE				TXRDY	RXRDY
Access	R	R	R				R	R
Reset	0	0	0				0	0

Bit 31 – COMMRX Mask COMMRX (from Arm) Interrupt

Bit 30 – COMMTX Mask COMMTX (from Arm) Interrupt

Bit 9 – TXEMPTY Mask TXEMPTY Interrupt

Bit 8 – TIMEOUT Mask Timeout Interrupt

Bit 7 – PARE Mask Parity Error Interrupt

Bit 6 – FRAME Mask Framing Error Interrupt

Bit 5 – OVRE Mask Overrun Error Interrupt

Bit 1 – TXRDY Disable TXRDY Interrupt

Bit 0 – RXRDY Mask RXRDY Interrupt

37.6.6. DBGU Status Register

Name: DBGU_SR
Offset: 0x0014
Reset: –
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	COMMRX	COMMTX						
Access	R	R						
Reset	–	–						

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
							TXEMPTY	TIMEOUT
Access							R	R
Reset							–	–

Bit	7	6	5	4	3	2	1	0
	PARE	FRAME	OVRE				TXRDY	RXRDY
Access	R	R	R				R	R
Reset	–	–	–				–	–

Bit 31 – COMMRX Debug Communication Channel Read Status

Value	Description
0	COMMRX from the Arm processor is inactive.
1	COMMRX from the Arm processor is active.

Bit 30 – COMMTX Debug Communication Channel Write Status

Value	Description
0	COMMTX from the Arm processor is inactive.
1	COMMTX from the Arm processor is active.

Bit 9 – TXEMPTY Transmitter Empty

Value	Description
0	There are characters in DBGU_THR, or characters are being processed by the transmitter, or the transmitter is disabled.
1	There are no characters in DBGU_THR and there are no characters being processed by the transmitter.

Bit 8 – TIMEOUT Receiver Timeout

Value	Description
0	There has not been any timeout since the last Start timeout command (DBGU_CR.STTTO), or the Timeout register is 0.
1	There has been a timeout since the last Start timeout command (DBGU_CR.STTTO).

Bit 7 – PARE Parity Error

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	No parity error has occurred since the last RSTSTA.
1	At least one parity error has occurred since the last RSTSTA.

Bit 6 – FRAME Framing Error

Value	Description
0	No framing error has occurred since the last RSTSTA.
1	At least one framing error has occurred since the last RSTSTA.

Bit 5 – OVRE Overrun Error

Value	Description
0	No overrun error has occurred since the last RSTSTA.
1	At least one overrun error has occurred since the last RSTSTA.

Bit 1 – TXRDY Transmitter Ready

Value	Description
0	A character has been written to DBGU_THR and not yet transferred to the internal shift register, or the transmitter is disabled.
1	There is no character written to DBGU_THR that is not yet transferred to the internal shift register.

Bit 0 – RXRDY Receiver Ready

Value	Description
0	No character has been received since the last read of DBGU_RHR, or the receiver is disabled.
1	At least one complete character has been received, transferred to DBGU_RHR, and not yet read.

© 2026 Microchip Technology Inc. and its subsidiaries

37.6.7. DBGU Receiver Holding Register

Name: DBGU_RHR
Offset: 0x0018
Reset: 0x0000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	RXCHR[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 7:0 – RXCHR[7:0] Received Character
Last received character if RXRDY is set.

© 2026 Microchip Technology Inc. and its subsidiaries

37.6.8. DBGU Transmit Holding Register

Name: DBGU_THR
Offset: 0x001C
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	TXCHR[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bits 7:0 – TXCHR[7:0] Character to be Transmitted
Next character to be transmitted after the current character if TXRDY is not set.

© 2026 Microchip Technology Inc. and its subsidiaries

37.6.9. DBGU Baud Rate Generator Register

Name: DBGU_BRGR
Offset: 0x0020
Reset: 0x0000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	CD[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	CD[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 15:0 – CD[15:0] Clock Divisor

Value	Description
0	Baud rate clock is disabled.
1	1 to 65,535: If BRSRCCK = 0: $CD = \frac{f_{peripheral\ clock}}{16 \times Baud\ Rate}$ If BRSRCCK = 1: $CD = \frac{f_{GCLKx}}{16 \times Baud\ Rate}$

© 2026 Microchip Technology Inc. and its subsidiaries

37.6.10. DBGU Receiver Timeout Register

Name: DBGU_RTOR
Offset: 0x0028
Reset: 0x0000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	TO[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 7:0 – TO[7:0] Timeout Value

Value	Description
0	The receiver timeout is disabled.
1–255	The receiver timeout is enabled and the timeout delay is TO x bit period.

© 2026 Microchip Technology Inc. and its subsidiaries

37.6.11. DBGU Chip ID Register

Name: DBGU_CIDR
Offset: 0x0040
Reset: –
Property: Read-only

For detailed reset values, refer to Chip Identifier.

Bit	31	30	29	28	27	26	25	24
	EXT	ID[25:19]						
Access	R	R	R	R	R	R	R	R
Reset	–	–	–	–	–	–	–	–

Bit	23	22	21	20	19	18	17	16
	ID[18:11]							
Access	R	R	R	R	R	R	R	R
Reset	–	–	–	–	–	–	–	–

Bit	15	14	13	12	11	10	9	8
	ID[10:3]							
Access	R	R	R	R	R	R	R	R
Reset	–	–	–	–	–	–	–	–

Bit	7	6	5	4	3	2	1	0
	ID[2:0]			VERSION[4:0]				
Access	R	R	R	R	R	R	R	R
Reset	–	–	–	–	–	–	–	–

Bit 31 – EXT Extension Flag

Value	Description
0	Chip ID has a single register definition without extension.
1	An extended Chip ID exists.

Bits 30:5 – ID[25:0] Product ID Value

Bits 4:0 – VERSION[4:0] Version of the Device
Values depend on the version of the device.

© 2026 Microchip Technology Inc. and its subsidiaries

37.6.12. DBGU Chip ID Extension Register

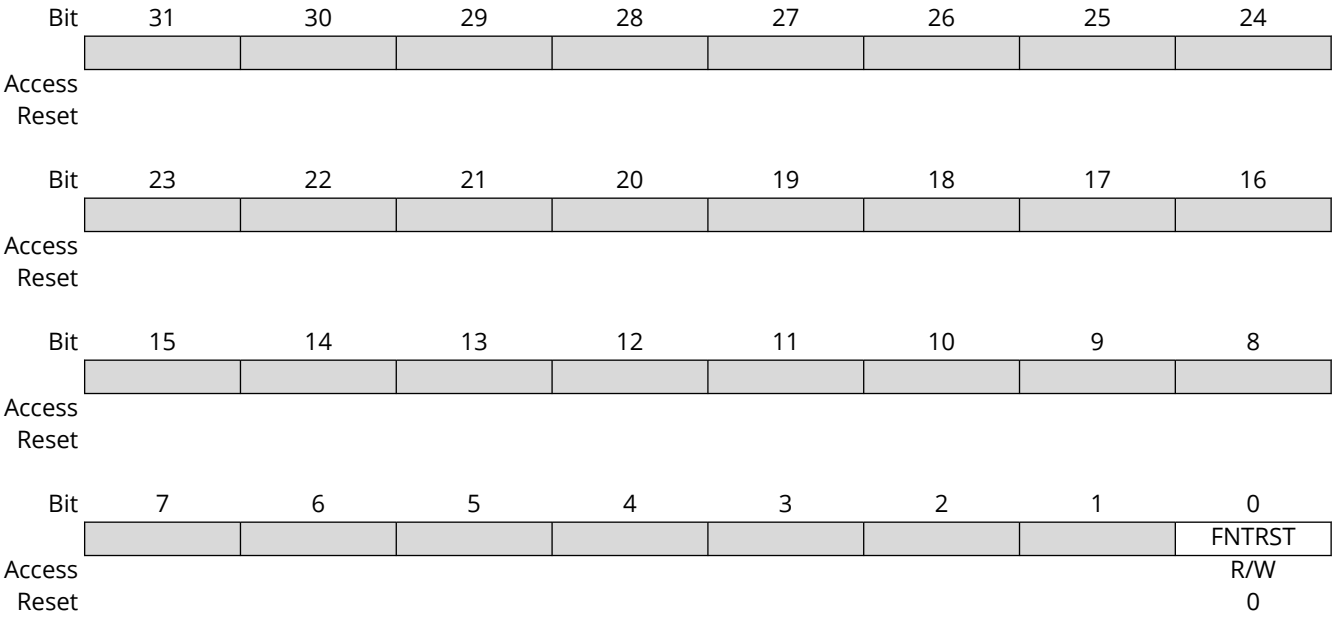
Name: DBGU_EXID
Offset: 0x0044
Reset: –
Property: Read-only

For detailed reset values, refer to Chip Identifier.

Bit	31	30	29	28	27	26	25	24
	EXID[31:24]							
Access	R	R	R	R	R	R	R	R
Reset	–	–	–	–	–	–	–	–

Bit	23	22	21	20	19	18	17	16
	EXID[23:16]							
Access	R	R	R	R	R	R	R	R
Reset	–	–	–	–	–	–	–	–

Bit	15	14	13	12	11	10	9	8
	EXID[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	–	–	–	–	–	–	–	–



Bit	7	6	5	4	3	2	1	0
	EXID[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	–	–	–	–	–	–	–	–

Bits 31:0 – EXID[31:0] Chip ID Extension
Read as 0 if DBGU_CIDR.EXT=0.

© 2026 Microchip Technology Inc. and its subsidiaries

37.6.13. Debug Unit Force NTRST Register

Name: DBGU_FNR
Offset: 0x0048
Reset: 0x00000000
Property: Read/Write

Bit 0 – FNTRST Force NTRST

Value	Description
0	NTRST of the Arm processor's TAP controller is driven by the power_on_reset signal.
1	NTRST of the Arm processor's TAP controller is held low.

© 2026 Microchip Technology Inc. and its subsidiaries

37.6.14. DBGU Write Protection Mode Register

Name: DBGU_WPMR
Offset: 0x00E4
Reset: 0x0000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
	WPKEY[23:16]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16
	WPKEY[15:8]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8
	WPKEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
								WPEN
Access								R/W
Reset								0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x554152	PASSWD	Writing any other value in this field aborts the write operation. Always reads as 0.

Bit 0 – WPEN Write Protection Enable
See Register Write Protection for the list of registers that can be protected.

Value	Description
0	Disables the write protection if WPKEY corresponds to 0x554152 (DBGU in ASCII).
1	Enables the write protection if WPKEY corresponds to 0x554152 (DBGU in ASCII).

© 2026 Microchip Technology Inc. and its subsidiaries

38. Special Function Registers (SFR)

38.1. Description

Special Function Registers (SFR) manage specific aspects of the integrated memory, bridge implementations, processor and other functionality not controlled elsewhere.

38.2. Embedded Characteristics

- 32-bit Special Function Registers Control Specific Behavior of the Product

© 2026 Microchip Technology Inc. and its subsidiaries

38.3. Register Summary

38.3.1. EBI Chip Select Register

Name: SFR_CCFG_EBICSA
Offset: 0x04
Reset: 0x00000300
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode register.

Bit	31	30	29	28	27	26	25	24
							DDR_MP_EN	NFD0_ON_D16
Access							R/W	R/W
Reset							0	0

Bit	23	22	21	20	19	18	17	16
				DQIEN_F				
Access				R/W				
Reset				0				

Bit	15	14	13	12	11	10	9	8
							EBI_DBPDC	EBI_DBPUC
Access							R/W	R/W
Reset							1	1

Bit	7	6	5	4	3	2	1	0
						EBI_CS2A	EBI_CS1A	
Access						R/W	R/W	
Reset						0	0	

Bit 25 – DDR_MP_EN DDR Multiport Enable

Value	Description
0	DDR Multiport is disabled (default).
1	DDR Multiport is enabled, performance is increased.

Bit 24 – NFD0_ON_D16 NAND Flash Databus Selection

Value	Description
0	NAND Flash I/Os are connected to D0–D7 (default).
1	NAND Flash I/Os are connected to D16–D23.

Bit 20 – DQIEN_F Force Analog Input Comparator Configuration

Value	Description
0	No effect
1	Enables the input comparator in the VDDIOM I/O data lines. Must be set to one in an initialization phase whenever an MPDDRC external component (DDR2 or LPDDR) and an SMC external component (e.g., NAND Flash) are multiplexed on the D0-D15 bus.

Bit 9 – EBI_DBPDC EBI Data Bus Pulldown Configuration

Value	Description
0	EBI D0–D15 Data Bus bits are not internally pulled down.
1	EBI D0–D15 Data Bus bits are internally pulled down to the ground.

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 8 – EBI_DBPUC EBI Data Bus Pullup Configuration

Value	Description
0	EBI D0–D15 Data Bus bits are internally pulled up to the VDDIOM power supply.
1	EBI D0–D15 Data Bus bits are not internally pulled up.

Bit 2 – EBI_CS2A EBI Chip Select 2 Assignment

Value	Description
0	EBI Chip Select 2 is only assigned to the SMC and EBI_NCS2 behaves as defined by the SMC.
1	EBI Chip Select 2 is assigned to the SMC and the NAND Flash Logic is activated.

Bit 1 – EBI_CS1A EBI Chip Select 1 Assignment

Value	Description
0	EBI Chip Select 1 is assigned to the Static Memory Controller (SMC).
1	EBI Chip Select 1 is assigned to the AHB Multiport DDR-SDRAM Controller (MPDDRC).

© 2026 Microchip Technology Inc. and its subsidiaries

38.3.2. OHCI Interrupt Configuration Register

Name: SFR_OHCIICR
Offset: 0x10
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	UDPPUDIS							
Access	R/W							
Reset	0							

Bit	15	14	13	12	11	10	9	8
						SUSP2	SUSP1	SUSP0
Access						R/W	R/W	R/W
Reset						0	0	0

Bit	7	6	5	4	3	2	1	0
			APPSTART	ARIE		RES2	RES1	RES0
Access			R/W	R/W		R/W	R/W	R/W
Reset			0	0		0	0	0

Bit 23 – UDPPUDIS Reserved

Value	Description
0	Must write 0.

Bits 8, 9, 10 – SUSPx USB PORTx

Value	Description
0	Does not suspend USB PORTx.
1	Forces PORTx suspend.

Bit 5 – APPSTART Reserved

Value	Description
0	Must write 0.

Bit 4 – ARIE OHCI Asynchronous Resume Interrupt Enable

Value	Description
0	Disables interrupt.
1	Enables interrupt.

Bits 0, 1, 2 – RESx USB PORTx Reset

Value	Description
0	No effect (USB PORTx reset released, default value)
1	Resets USB PORTx.

© 2026 Microchip Technology Inc. and its subsidiaries

38.3.3. OHCI Interrupt Status Register

Name: SFR_OHCIISR
Offset: 0x14
Reset: 0x00000000
Property: Read-only

This register can only be written if the WPEN bit is cleared in the Write Protection Mode register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Bit	7	6	5	4	3	2	1	0
Access								
Reset								

Bits 8:10, 12:14, 16:18 – SLOPEx UTMI HS PORTx Transceiver Slope Trimming
Adjusts HS transceiver output slope for PORTx.
These bits are duplicated for each port because the HS slope depends on the PCB line length. Short lines appear as lumped capacitances and exhibit a slower rise/fall time, while longer lines appear as transmission lines with sharper edges.

38.3.7. SFR Light Sleep Register

Name: SFR_LS
Offset: 0xA0
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode register.

The following configuration values are valid for all listed LSx bit names of this register:

0: Disables Light Sleep mode.

1: Enables Light Sleep mode.

Bit	31	30	29	28	27	26	25	24

Reset	0	0	0	0	0	0	0	0

Bit 16 – MEM_POWER_GATING_ULP1_EN Light Sleep Value for ULP1 Power-Gated Memories
The memory power gating can be automatically enabled when entering ULP1 Low-power mode. Refer to the section “Electrical Characteristics”.

Value	Description
0	Light Sleep mode is not activated by the MEM_POWER_GATING_ULP1 output signal from the PMC.
1	Light Sleep mode is activated when the MEM_POWER_GATING_ULP1 output signal from the PMC is activated.

Bit 13 – LS13 Light Sleep Value (GMAC)

Bit 12 – LS12 Light Sleep Value (DSI)

Bit 11 – LS11 Light Sleep Value (ISC)

Bit 10 – LS10 Light Sleep Value (CSI2DC)

Bit 9 – LS9 Light Sleep Value (ARM926)

Bit 8 – LS8 Light Sleep Value (ROM + OTPC)

© 2026 Microchip Technology Inc. and its subsidiaries

Reset	1	0	0	0	0	1	0	0

Bit 8 – TEST_M Enable Calibration of Low/High Level Output Impedance of Pads with VDDIOM Supply
Enables calibration bits to adjust the low/high level output impedance of pads with power supply input VDDIOM.

Bits 7:4 – CALP_M[3:0] Calibration of High Level Output Impedance of Pads with VDDIOM Supply
Adjusts the high level output impedance of pads with power supply input VDDIOM.

Value	Name
0000	Minimum output impedance value
1111	Maximum output impedance value

Bits 3:0 – CALN_M[3:0] Calibration of Low Level Output Impedance of Pads with VDDIOM Supply
Adjusts the low level output impedance of pads with power supply input VDDIOM.

Value	Name
0000	Maximum output impedance value
1111	Minimum output impedance value

Reset	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8
	WPKEY[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
								WPEN
Access								R/W
Reset								0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x534652	PASSWD	Writing any other value in this field aborts the write operation of the WPEN bit. Always reads as 0.

Bit 0 – WPEN Write Protection Enable

Value	Description
0	Disables write protection if WPKEY corresponds to 0x534652 (“SFR” in ASCII).
1	Enables write protection if WPKEY corresponds to 0x534652 (“SFR” in ASCII).

© 2026 Microchip Technology Inc. and its subsidiaries

38.3.10. PUFSRAM Domain Control Register

Name: SFR_PUFCTL
Offset: 0x200
Reset: 0x00000148
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
							PHG	PLG
Access							R	R
Reset							0	1

Bit	7	6	5	4	3	2	1	0
		ALWAYSONE	PUFLTM	PUFDIS	PUFRST	PONOFFLZ	PONOFFHZ	PONOFFM
Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		1	0	0	1	0	0	0

Bit 9 – PHG PUFSRAM Power High Status
CAUTION: PHG is only 1 when the two power switches (HiZ and LoZ) are on. In other case PHG=0 and PLG=1.

Value	Description
0	PUFSRAM domain is not powered.
1	PUFSRAM domain is powered.

Bit 8 – PLG PUFSRAM Power Low Status

Value	Description
0	PUFSRAM domain is powered.
1	PUFSRAM domain is not powered.

Bit 6 – ALWAYSONE Must always be programmed to 1

Bit 5 – PUFLTM PUF Lab Test Mode

Value	Description
0	No effect
1	Enters Test mode when PUFRST=0.

Bit 4 – PUFDIS Disable the PUF
CAUTION: This bit is write-once until the next chip reset.

Value	Description
0	No effect

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	PUF clock and psel signals are disabled by HW and PUFSRAM domain is off.

Bit 3 – PUFRST Reset for PUF IP

Value	Description
0	PUF is active.
1	PUF is in Reset mode.

Bit 2 – PONOFFLZ Controls Power Switch Low Z if PONOFFM=1

Value	Description
0	Power switch Low Z is off.
1	Power switch Low Z is on.

Bit 1 – PONOFFHZ Controls Power Switch High Z if PONOFFM=1

Value	Description
0	Power switch High Z is off.
1	Power switch High Z is on.

Bit 0 – PONOFFM PUFSRAM Power Switches Controlled Manually

CAUTION: When controlling power switches manually, apply the following sequence:

1. Write PONOFFHZ to 1.
2. Wait the time defined in the fuses (from 20 µs to 80 µs).
3. Write PONOFFLZ to 1.

Value	Description
0	Power switches are automatically controlled by SYSC at start-up.
1	Power switches are manually controlled by the PONOFFLZ and PONOFFHZ bits.

© 2026 Microchip Technology Inc. and its subsidiaries

38.3.11. PUF Disable Functions Register

Name: SFR_PUFDIS
Offset: 0x208
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the Write Protection Mode register.

CAUTION: This register only allows to write 'ones' and forbids to write 'zeros'. A chip reset is needed to clear this register.

The following configuration values are valid for all listed bit names of this register:

0: Operation is permitted.

1: Operation is forbidden.

Bit	31	30	29	28	27	26	25	24
Access

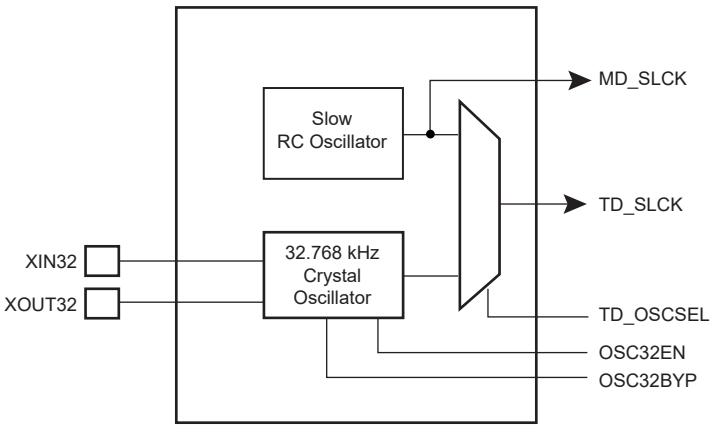
39. Slow Clock Controller (SCKC)

39.1. Description

The System Controller embeds a Slow Clock Controller (SCKC). The SCKC selects the slow clock for the RTT and the RTC from one of two sources:



- External 32.768 kHz crystal oscillator
- Embedded 32 kHz (typical) slow RC oscillator

39.2. Embedded Characteristics

- Embedded 32 kHz (Typical) Slow RC Oscillator or 32.768 kHz Crystal Oscillator Selector
- VDDBU-Powered

39.3. Block Diagram

Figure 39.1. SCKC Block Diagram

39.4. Functional Description

The TD_OSCSEL bit located in the Slow Clock Controller Configuration register (SCKC_CR) is in the backup domain and its value is kept while VDDBU is present.

The embedded 32 kHz (typical) slow RC oscillator is always enabled as soon as VDDBU is established. The Slow Clock Selector command TD_OSCSEL bit selects the slow clock source of the RTT and the RTC.

After the VDDBU Power-On-Reset, the default configuration is TD_OSCSEL = 0.

The programmer controls the slow clock switching by software, so precautions must be taken during the switching phase.

39.4.1. Switching from Embedded 32 kHz RC Oscillator to 32.768 kHz Crystal Oscillator

The sequence to switch from the embedded 32 kHz (typical) slow RC oscillator to the 32.768 kHz crystal oscillator is the following:

1. Switch the main system bus clock to a source different from slow clock (PLL or Main Oscillator) through the Power Management Controller.
2. Switch from the embedded 32 kHz RC oscillator to the 32.768 kHz crystal oscillator by writing a 1 to the TD_OSCSEL bit.
3. Wait 39000 slow clock cycles for internal resynchronization.

© 2026 Microchip Technology Inc. and its subsidiaries

39.4.2. Bypassing the 32.768 kHz Crystal Oscillator

The sequence to bypass the 32.768 kHz crystal oscillator is the following:

1. An external clock must be connected on XIN32.
2. Enable the bypass path by writing a 1 to the OSC32BYP bit.
3. Disable the 32.768 kHz crystal oscillator by writing a 0 to the OSC32EN bit.

39.4.3. Switching from 32.768 kHz Crystal Oscillator to Embedded 32 kHz RC Oscillator

The sequence to switch from the 32.768 kHz crystal oscillator to the embedded 32 kHz (typical) RC oscillator is the following:

1. Switch the main system bus clock to a source different from slow clock (PLL or Main Oscillator).
2. Switch from the 32.768 kHz crystal oscillator to the embedded RC oscillator by writing a 0 to the TD_OSCSEL bit.
3. Wait 5 slow clock cycles for internal resynchronization.
4. Disable the 32.768 kHz crystal oscillator by writing a 0 to the OSC32EN bit.

40. Clock Generator

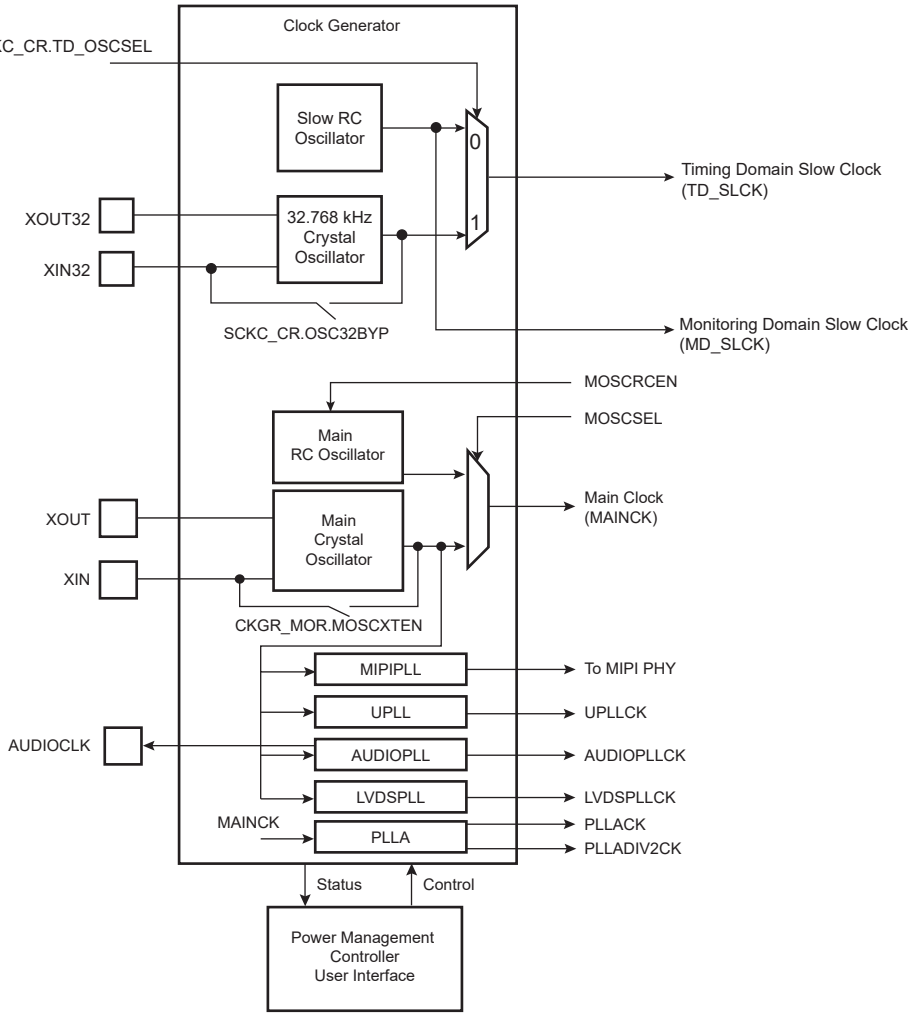
40.1. Description

The Clock Generator user interface is embedded within the Power Management Controller and is described in the Register Summary. However, the Clock Generator registers are named CKGR_.

40.2. Embedded Characteristics

The Clock Generator is made up of:

- Oscillators
  - A low-power 32.768 kHz oscillator supporting crystals, resonators and Bypass mode (referred to as “32.768 KHz crystal oscillator” throughout the document)
  - An embedded always-on, slow RC oscillator generating a typical 32 kHz clock
  - A 20 to 50 MHz oscillator supporting crystals, resonators and Bypass mode (referred to as “main crystal oscillator” throughout the document)
  - A main RC oscillator generating a typical 12 MHz clock
- Five fractional-N PLLs with an input range of 20 to 50 MHz and different internal frequency ranges
  - System PLL (PLLA) - PLL ID0
  - USB High-speed PLL (UPLL) - PLL ID1
  - Audio PLL (AUDIOPLL) - PLL ID2
  - LVDS PLL (LVDSPLL) - PLL ID3
  - System PLL divided by 2 (PLLADIV2) - PLL ID4



The Clock Generator provides the following clocks:

- MD_SLCK—Monitoring domain slow clock. This clock, sourced from the always-on slow RC oscillator only, is the only permanent clock of the system and feeds safety-critical functions of the device (WDT, RSTC, SCKC, frequency monitors and detectors, PMC start-up time counters).
- TD_SLCK—Timing domain slow clock. This clock, sourced from the 32.768 kHz crystal oscillator or the always-on slow RC oscillator, is routed to the RTC and RTT peripherals.
- MAINCK—Output of the main clock oscillator selection. This clock is either the main crystal oscillator or the main RC oscillator.
- PLL Clocks—Outputs of embedded PLLs

© 2026 Microchip Technology Inc. and its subsidiaries

40.3. Block Diagram

Figure 40.1. Clock Generator Block Diagram

40.4. Slow Clock

The PMC does not control the slow clock generation. The control of the slow clock is performed by the Slow Clock Controller (SCKC) which embeds a slow clock generator that is supplied with the VDDBU power supply. As soon as VDDBU is supplied, both the 32.768 kHz crystal oscillator and the slow RC oscillator are powered, but only the slow RC oscillator is enabled.

MD_SLCK is always generated by the slow RC oscillator.

TD_SLCK is generated either by the 32.768 kHz crystal oscillator or by the slow RC oscillator.

The TD_SLCK source clock selection is made via the TD_OSCSEL bit in the Slow Clock Controller Configuration register (SCKC_CR).

40.4.1. Slow RC Oscillator (32 kHz typical)

The slow RC oscillator is a permanent clock that is the source clock of MD_SLCK and the default source clock of TD_SLCK.

Compared to the 32.768 kHz crystal oscillator, this oscillator offers a faster start-up time and is less exposed to the external environment, as it is fully integrated. However, its output frequency is subject to larger variations with supply voltage, temperature and manufacturing process. Therefore,

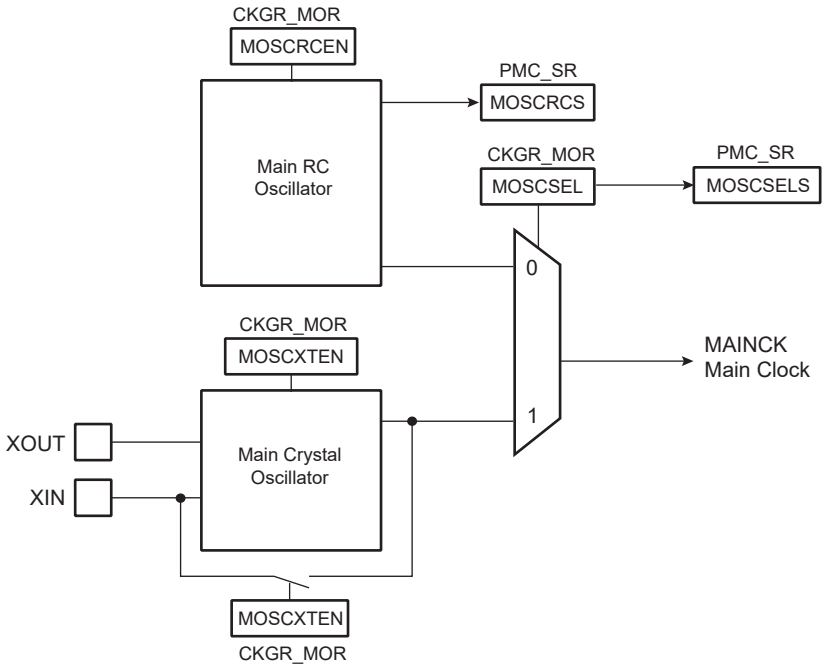
© 2026 Microchip Technology Inc. and its subsidiaries

the user must take these variations into account when this oscillator is used as a time base (start-up counter, frequency monitor, etc.). Refer to the section “Electrical Characteristics”.

40.4.2. 32.768 kHz Crystal Oscillator

By default, the 32.768 kHz oscillator is disabled. To use this oscillator, the XIN32 and XOUT32 pins must be connected to a 32.768 kHz crystal or to a ceramic resonator. Refer to the section “Electrical Characteristics” for appropriate loading capacitors selection on XIN32 and XOUT32.

To select the 32.768 kHz crystal oscillator as the source of TD_SLCK, SCKC_CR.TD_OSCSEL must be set to 1. The switch of TD_SLCK source is glitch-free.



The user can also set the 32.768 kHz crystal oscillator in Bypass mode instead of connecting a crystal. In this case, the user must provide the external clock signal on XIN32. For input characteristics of the XIN32 pin, refer to the section “Electrical Characteristics”. To enter Bypass mode, the OSC32BYP bit of the Slow Clock Controller Configuration register (SCKC_CR) must be set to 1 prior to setting SCKC_CR.TD_OSCSEL.

40.5. Main Clock

The main clock (MAINCK) has two sources:

- A main RC oscillator with a fast start-up time and that is selected by default to start the system
- A main crystal oscillator with Bypass mode

Figure 40.2. Main Clock (MAINCK) Block Diagram

40.5.1. Main RC Oscillator

After reset, the main RC oscillator is enabled. This oscillator is selected as the source of MAINCK. MAINCK is the default clock selected to start the system.

The main RC oscillator is calibrated in production. For output frequency specifications, refer to the section “Electrical Characteristics”.

The software can disable or enable the main RC oscillator with the MOSCRCEN bit in the Clock Generator Main Oscillator register (CKGR_MOR).

© 2026 Microchip Technology Inc. and its subsidiaries

When disabling the main RC oscillator by clearing the CKGR_MOR.MOSCRCEN bit, the PMC_SR.MOSCRCS bit is automatically cleared, indicating that the oscillator is off.

Setting the MOSCRCS bit in the Power Management Controller Interrupt Enable Register (PMC_IER) triggers an interrupt to the processor.

40.5.2. Main Crystal Oscillator

After reset, the main crystal oscillator is disabled and is not selected as the source of MAINCK.

The software enables or disables this oscillator in order to reduce power consumption via CKGR_MOR.MOSCXTEN.

When disabling this oscillator by clearing CKGR_MOR.MOSCXTEN, the PMC_SR.MOSCXTS status bit is automatically cleared, indicating the oscillator is off. To activate the Main Crystal Oscillator Bypass mode, see Bypassing the Main Crystal Oscillator.

When enabling this oscillator, the user must initiate the start-up time counter. The start-up time depends on the characteristics of the external device connected to this oscillator.

When CKGR_MOR.MOSCXTEN and CKGR_MOR.MOSCXTST are written to enable this oscillator, XIN and XOUT are driven by the main crystal oscillator. PMC_SR.MOSCXTS is cleared and the counter starts counting down on MD_SLCK divided by 8 from the CKGR_MOR.MOSCXTST value. Since the CKGR_MOR.MOSCXTST value is coded with 8 bits, the start-up time can be programmed up to 2048 MD_SLCK periods, corresponding to about 62 ms when running at 32.768 kHz.

When the start-up time counter reaches ‘0’, PMC_SR.MOSCXTS is set, indicating that the oscillator is stabilized. Setting the MOSCXTS bit in the Interrupt Mask Register (PMC_IMR) can trigger an interrupt to the processor.

40.5.3. Main Clock Source Selection

The source of MAINCK can be selected from the following:

- the main RC oscillator
- the main crystal oscillator
- an external clock signal provided on the XIN input (Bypass mode of the main crystal oscillator)

The advantage of the main RC oscillator is its fast start-up time. By default, this oscillator is selected to start the system and it must be selected prior to entering ULP1 mode.

The advantage of the main crystal oscillator is its high level of accuracy.

The selection of the oscillator is made by configuring CKGR_MOR.MOSCSEL. The switchover of the MAINCK source is glitch-free, thus the switchover can be performed even if MCK is fed by MAINCK. PMC_SR.MOSCSELS indicates when the switch sequence is done.

Setting PMC_IMR.MOSCSELS triggers an interrupt to the processor.

40.5.4. Bypassing the Main Crystal Oscillator

Prior to bypassing the main crystal oscillator, the XOUT pin must be grounded and the external clock frequency provided on the XIN pin must be stable and within the values specified in the XIN Clock characteristics in the section “Electrical Characteristics”. Then the main crystal oscillator must be enabled by setting the CKGR_MOR.MOSCXTEN bit to 1.

40.5.5. Main Frequency Counter

The main frequency counter measures the main RC oscillator or the main crystal oscillator against the MD_SLCK and is managed by CKGR_MCFR.

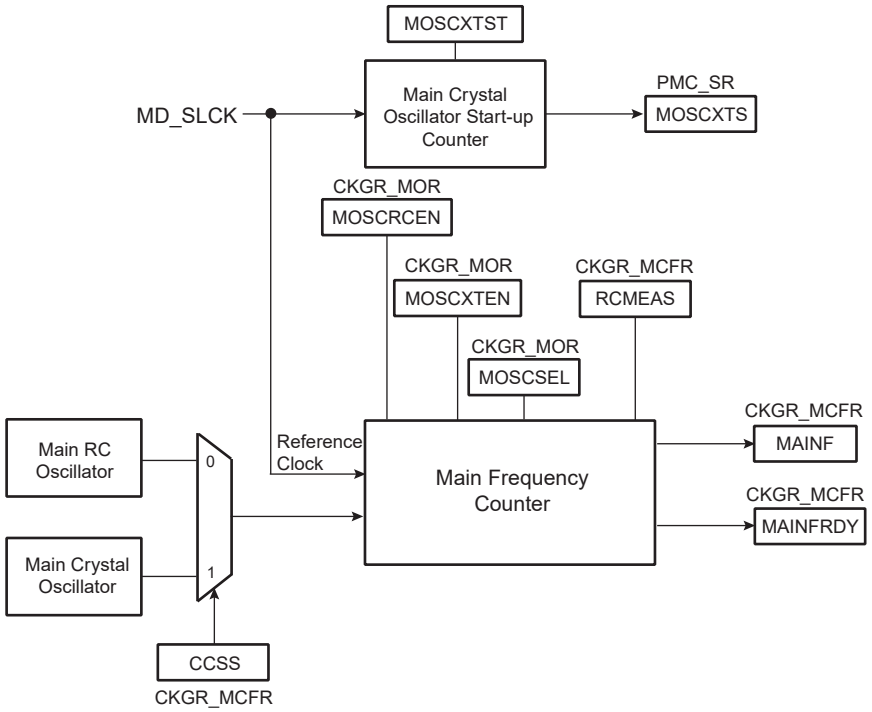
During the measurement period, the main frequency counter increments at the speed of the clock defined by the bit CKGR_MCFR.CCSS.

© 2026 Microchip Technology Inc. and its subsidiaries

A measurement is started in the following cases:

- When CKGR_MCFR.RCMEAS is written to '1'.
- When the main RC oscillator is selected as the source of MAINCK and when this oscillator is stable (i.e., when the MOSCRCS bit is set)
- When the main crystal oscillator is selected as the source of MAINCK and when this oscillator is stable (i.e., when the MOSCXTS bit is set)
- When MAINCK source selection is modified

The measurement period ends at the 16th falling edge of MD_SLCK, the MAINFRDY bit in CKGR_MCFR is set and the counter stops counting. Its value can be read in the MAINF field of CKGR_MCFR and indicates the number of clock cycles during 16 periods of MD_SLCK, so that the frequency of the main RC oscillator or main crystal oscillator can be determined.



When switching the source of MAINCK from the main RC oscillator to the main crystal oscillator, follow the programming sequence below to ensure that the oscillator is present and that its frequency is valid:

1. Enable the main crystal oscillator by setting CKGR_MOR.MOSCXTEN. Configure the CKGR_MOR. MOSCXTST field with the main crystal oscillator start-up time as defined in the section "Electrical Characteristics".
2. Wait for PMC_SR.MOSCXTS flag to rise, indicating the end of a start-up period of the main crystal oscillator.
3. Select the main crystal oscillator as the source clock of the main frequency counter by setting CKGR_MCFR.CCSS.
4. Initiate a frequency measurement by setting CKGR_MCFR.RCMEAS.
5. Read CKGR_MCFR.MAINFRDY until its value equals 1.
6. Read CKGR_MCFR.MAINF and compute the value of the main crystal frequency.

If the MAINF value is valid, software can switch MAINCK to the main crystal oscillator. See Main Clock Source Selection.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 40.3. Main Frequency Counter Block Diagram

40.6. PLL Controls

The PMC embeds 4 PLLs that are controlled by the PMC_PLL_CTRL0, PMC_PLL_CTRL1, PMC_PLL_SSR, PMC_PLL_ACR and PMC_PLL_UPDATE registers. Each PLL is accessed in read or write through its index as defined in the table below, corresponding to the register field PMC_PLL_UPDT.ID. At any time, PLL_CTRL0, PLL_CTRL1 and PLL_ACR reflect the controls for the PLL with index PMC_PLL_UPDT.ID. When the UPDATE bit is set in PMC_PLL_UPDT, the PLL of index PMC_PLL_UPDT.ID is updated with the content of registers PLL_CTRL0, PLL_CTRL1 and PLL_ACR.

Each PLL is fed by either the MAINCK or the main crystal oscillator and has a constraint on the frequency it can generate on its clock output. Refer to the section “Electrical Characteristics”.

The table below describes all PLLs with their names and source clocks. For maximum frequency, refer to the section “Electrical Characteristics”.

Table 40.1. PLL IDs

Index	PLL Name	Clock Name	PLL Clock Source	Usage Example
0	PLLA	PLLACK	MAINCK	CPU_CLK and MCK clock sources
1	UPLL	ULLCK	MAIN XTAL OSC	UTMI clock source
2	AUDIOPLL	AUDIOPLLCK	MAIN XTAL OSC	AUDIOCLK output clock source
3	LVDSPLL	LVDSPLLCK	MAIN XTAL OSC	LVDS clock source
4	PLLADIV2	PLLADIV2CK	MAINCK	Generic clocks source

40.6.1. Divider and Phase Lock Loop Programming

Each PLL is controlled the same way. The internal clock frequency is configured by setting PMC_PLL_CTRL1.MUL and PMC_PLL_CTRL1.FRACR, then two division ratios are applied on the internal PLL clock:

- The first division ratio generates the PLL clock for the PMC.

© 2026 Microchip Technology Inc. and its subsidiaries

- The second division ratio generates a clock for a dedicated output line (IOPLLCKx). This feature generates an output clock signal with improved jitter performance. It is not available for all PLLs. Refer to PLL Characteristics in the section “Electrical Characteristics” for more information.

The COREPLLCK operating frequency is defined by the following formula:

$$f_{\mathrm{COREPLLCK}} = f_{\mathrm{ref}}\left(\mathrm{MUL} + 1 + \frac{\mathrm{FRACR}}{2^{22}}\right)$$

The PLLA (ID0) clock frequency is defined by the following formula:

$$f_{\mathrm{PLLA\ Clock}} = \frac{f_{\mathrm{COREPLLACK}}}{2 \times (\mathrm{DIVPMC} + 1)}$$

Note: The PLL general frequency is not applied to PLLA.

The UPLL clock frequency is defined by the following formula:

$$f_{\mathrm{UPLL\ Clock}} = \frac{f_{\mathrm{COREUPLLCK}}}{2}$$

The IOPLLCK frequency is defined by the following formula:

$$f_{\mathrm{IOPLLCK}} = \frac{f_{\mathrm{COREPLLCK}}}{(\mathrm{DIVIO}+1)}$$

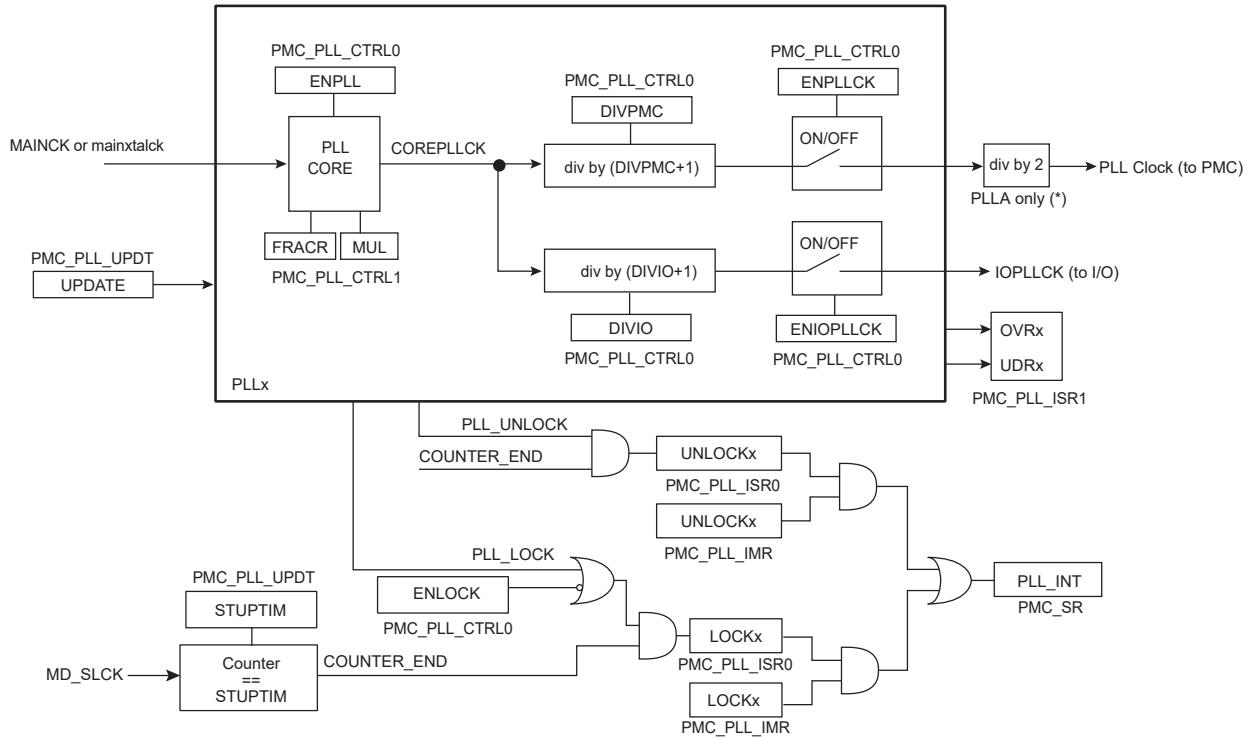
Each PLL sends a lock signal to the PMC to indicate its lock status. Once the lock signal has risen, the clock generated by the PLL is stable and can be sent to the PMC and/or its corresponding IO if available.

This signal reports the lock status of the PLL by setting the corresponding PMC_PLL_CTRL0.ENLOCK to ‘1’.

If the lock status is disabled, a start-up time can be used instead in the PMC_PLL_UPDT register. The start-up time is expressed as a number of MD_SLCK cycles. Once the counter has reached the specified value, a flag rises. The start-up time field can only be written while all PLLs are disabled (i.e., their PLLEN fields are null).

If both a start-up time and the lock are enabled, the lock sent by the PLL is read once the start-up time has elapsed.

If neither the start-up time nor the lock are enabled, there is no way to know the lock status of the PLL.



The PLL also embeds an unlock status that informs when the PLL lock is lost. When enabled, this status is read once the start-up time (if defined) has elapsed.

The lock and unlock status can be used as interrupts.

See the following figure.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 40.4. PLL Controls

(*): This divider is only implemented at the output of PLLA (ID0).

Follow the steps below to enable a PLL:

1. Define the ID (ID=n) and start-up time by configuring the fields PMC_PLL_UPDT.ID and PMC_PLL_UPDT.STUPTIM. Set PMC_PLL_UPDT.UPDATE to ‘0’.
2. Configure PMC_PLL_ACR. See recommended values in the Electrical Characteristics section.
3. Define the MUL and FRACR to be applied to PLL(n) in PMC_PLL_CTRL1.
   If UPLL is being configured, follow Step 4. to Step 7., otherwise jump to Step 8.
4. Write PMC_PLL_ACR.UTMIBG to ‘1’ to enable the UTMI internal bandgap.
5. Wait 10 µs.
6. Write PMC_PLL_ACR.UTMIVR to ‘1’ to enable the UTMI internal regulator.
7. Wait 10 µs.
8. Set PMC_PLL_UPDT.UPDATE to ‘1’. PMC_PLL_UPDT.ID must equal the one written during Step 1., otherwise the update is cancelled.
9. In PMC_PLL_CTRL0, write a ‘1’ to ENLOCK and to ENPLL and configure DIVPMC (for PLLA only, as UPLL has a fixed divider value), DIVIO, ENPLLCK and ENIOPLLCK.
10. Set PMC_PLL_UPDT.UPDATE to ‘1’. PMC_PLL_UPDT.ID must equal the one written during Step 1. otherwise the update is cancelled.
11. Wait for the lock bit to rise by polling the PMC_PLL_ISR0 or by enabling the corresponding interrupt in PMC_PLL_IER.
12. Disable the interrupt (if enabled).
13. Enable the unlock interrupt to quickly detect a failure on the generation of the PLL clock.

© 2026 Microchip Technology Inc. and its subsidiaries

Once enabled (PMC_PLL_CTRL0.ENPLL=1), the PLL core generates its core clock (COREPLLCK).

Once the PLL has been enabled and has locked, the PLL configuration can be modified without switching off the cell.

The clock generated by the PLL is sent to the PMC if ENPLLCK is set to '1' and the PMC_PLL_UPDT.UPDATE bit has then been written to '1'.

The clock generated by the AUDIOPLL is sent to the IO only if ENIOPLLCK was set to 1 and then PMC_PLL_UPDT.UPDATE was written to 1.

To disable a PLL, the following sequence must be applied:

1. If the PLL drives a section of the system that is active, modify the source clock of the system.
2. Define the ID (ID=n) of the PLL to be switched off in PMC_UPDT. The bit UPDATE in this register must be set at 0 in this step.
3. In PMC_PLL_CTRL0, set ENPLLCK and ENIOPLLCK to 0 and leave ENPLL at '1'.
4. Set PMC_PLL_UPDT.UPDATE to '1'. PMC_PLL_UPDT.ID must equal the one written during step 2, otherwise the update is cancelled.
5. Write a '0' to PMC_PLL_CTRL0.ENPLL.
6. Set PMC_PLL_UPDT.UPDATE to '1'. PMC_PLL_UPDT.ID must equal the one written during Step 2., otherwise the update is cancelled.

40.6.2. UTMI PLL

The UTMI PLL is not controllable by PMC_PLL_CTRL0/1. It can be enabled by PMC_PLL_ACR. To specify the currently used main crystal frequency to the UTMI PHY, set the applicable value in PMC_XTALF.XTALF.

40.6.3. PLL Unlock

Each PLL has an unlock flag. It is recommended to set the UNLOCK interrupt by setting the corresponding PMC_PLL_IER.UNLOCK bit to quickly detect a failure on PLL clock generation.

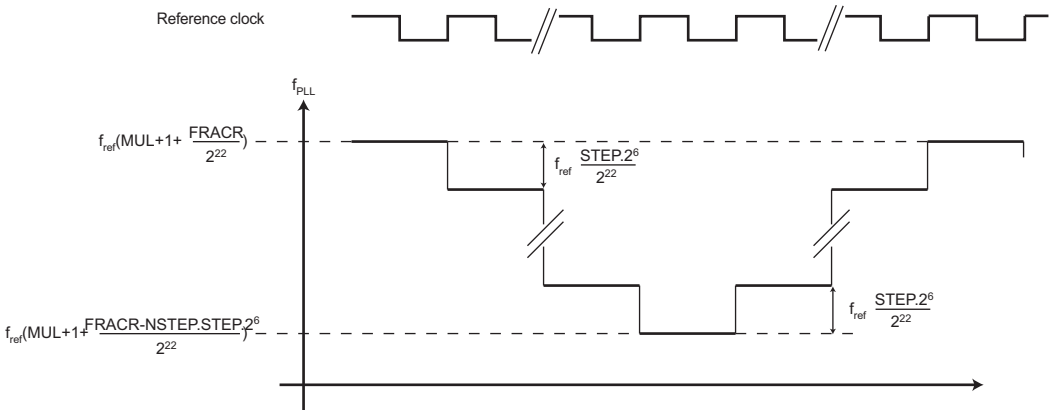
The rise of a PLL unlock signal implies a failure in the normal operation of the PLL (input clock loss, for example). In this case, the PLL keeps operating but stops trying to lock the input clock. A manual clock switching to a stable clock should be performed to ensure CPU_CLK integrity.

40.6.4. Spread Spectrum

Spread spectrum is obtained by slightly modifying the PLL target frequency. Two parameters are used to configure the spread spectrum:

- STEP—the frequency step
- NSTEP—the number of times the STEP will be applied

The spread spectrum can be applied only if the PLL is already enabled and locked. Once the spread spectrum has been enabled, it is no longer possible to modify the target frequency of the PLL. Prior to changing the PLL frequency, the spread spectrum must be disabled and a period of 2 x NSTEP cycles of the PLL source clock must elapse.



When enabled, the spread spectrum logic modifies the fractional part of the PLL. The fractional factor applied to the PLL is in the following range: FRACR - (64 x STEP x NSTEP) up to FRACR.

Starting from the base frequency of the PLL configured in PMC_PLL_CTRL1 (MUL, FRACR), the spread spectrum mechanism decreases t

he PLL frequency, and when the minimum is reached, the PLL frequency is increased up to the value configured through the PMC_PLL_CTRL1 register (the PLL frequency never overpasses that value).

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 40.5. Spread Spectrum Mechanism

When enabling the spread spectrum function, several restrictions appear on the FRACR value that lead to modifying FRACR by one unit on very specific configurations. Observe the following sequence to ensure proper operation of the PLL:

1. Calculate the PLL core frequency ($f_{COREPLLCK}$) parameters (MUL and FRACR) as described in Divider and Phase Lock Loop Programming.
2. Calculate the spread spectrum parameters (STEP and NSTEP) as described above.
3. Depending on the FRACR, STEP and NSTEP values, the following four cases must be considered to verify whether FRACR needs adjustment or not:
   a. If (FRACR = 2^{22} - 1), configure FRACR = FRACR – 1.
   b. If (FRACR > NSTEP x STEP x 64), no change is required on FRACR.
   c. If (FRACR + k x 2^{22} = p x STEP x 64)(1), configure FRACR = FRACR + 1.
   d. If (FRACR + 1 + k x 2^{22} = p x STEP x 64)(1), configure FRACR = FRACR - 1.
4. Program the PLL according to the FRACR value found in step 3.
5. Program STEP and NSTEP.
6. Enable the PLL.
7. Enable the spread spectrum(2).

Notes:

1. k is zero or a positive integer, and p is an integer in the [1,NSTEP] range.
2. The spread spectrum can be enabled only if the PLL is already running.

© 2026 Microchip Technology Inc. and its subsidiaries

41. Power Management Controller (PMC)

41.1. Description

The Power Management Controller (PMC) optimizes power consumption by controlling all system and user peripheral clocks. The PMC enables/disables the clock inputs to many of the peripherals and to the processor.

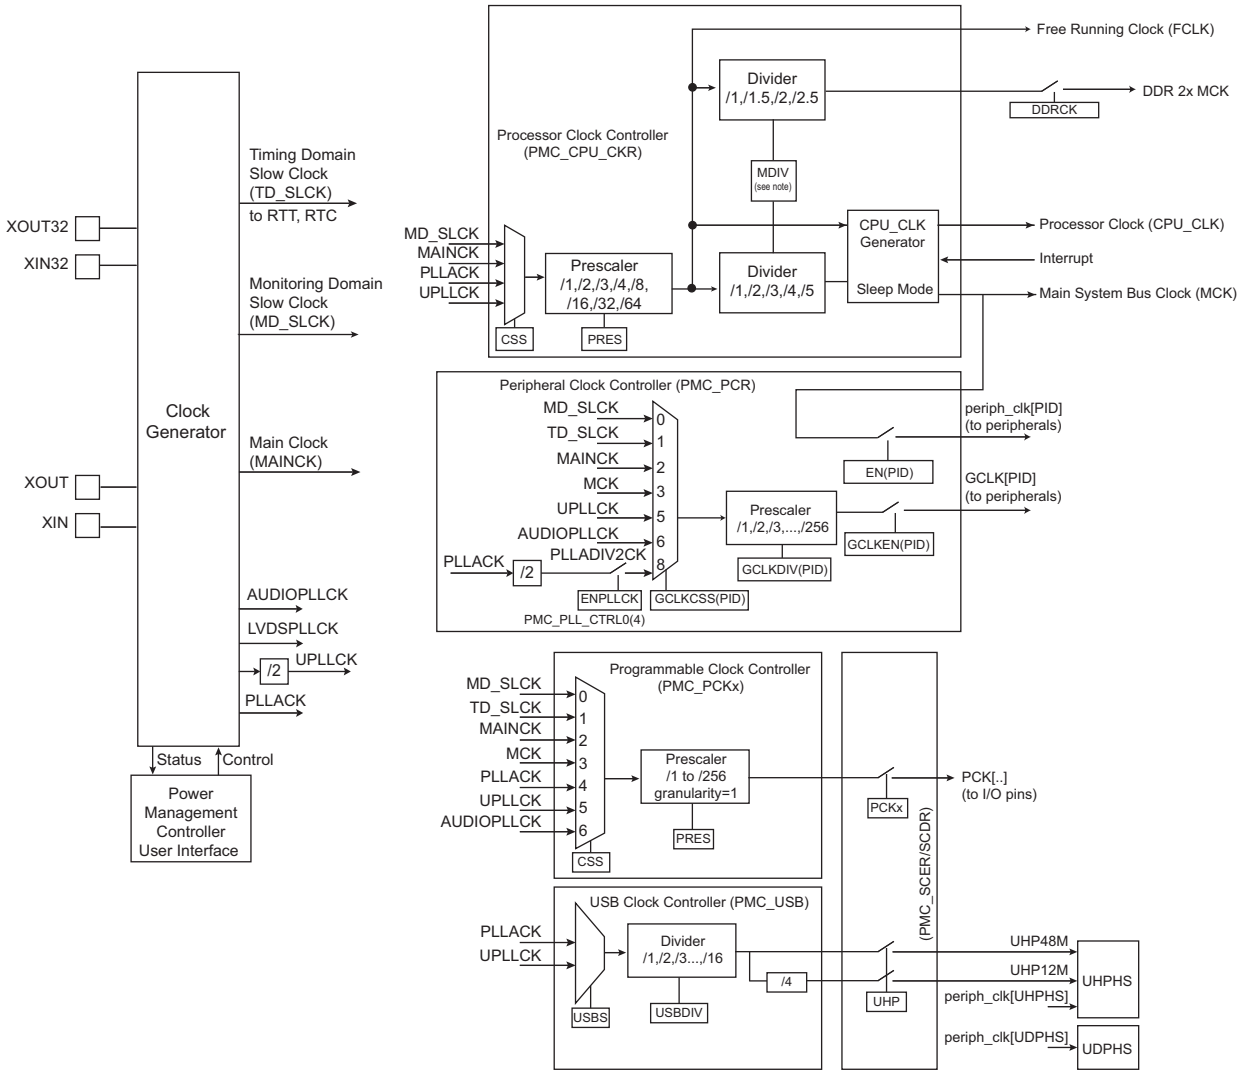
The Slow Clock Controller (SCKC) selects the source of TD_SLCK (drives the real-time part (RTT/RTC)). The source of MD_SLCK (drives the rest of the system controller: wake-up logic, watchdog, PMC, etc.) is always the slow RC oscillator.

By default, at start-up, the chip runs out of MCK using the main RC oscillator.

41.2. Embedded Characteristics

The Power Management Controller provides the following clocks:

- Main System Bus Clock (MCK)—programmable from a few hundred Hz to the maximum operating frequency of the device. It is available to the modules running permanently.
- Processor Clock (CPU_CLK)—can be tuned through a frequency scaler module and automatically switched off when entering the processor in Sleep mode.
- Free-Running Processor Clock (FCLK)—the source clock of CPU_CLK. Is not affected when Sleep mode is activated.
- UHDP Clocks (UHP48M and UHP12M)—required by USB Host Device Port operations.
- Peripheral Clocks with independent on/off control, provided to the peripherals. Each peripheral clock is inherited from MCK.
- Programmable Clock Outputs (PCKx), selected from the clock generator outputs to drive the device PCKx pins.
- Generic Clock (GCLK) with controllable division and on/off control, independent of MCK and CPU_CLK. Provided to selected peripherals. Refer to the table “Peripheral Identifiers” for more details on GCLK availability per peripheral.



The Power Management Controller also provides the following features on clocks:

- A main crystal oscillator failure detector
- A 32.768 kHz crystal oscillator frequency monitor
- A frequency counter on main crystal oscillator or main RC oscillator
- An MCK failure detector

© 2026 Microchip Technology Inc. and its subsidiaries

41.3. Block Diagram

Figure 41.1. General Clock Distribution Block Diagram

Note: MDIV should always be different from 0 when using DDR memories. If MDIV must be set to 0, first switch the DDR memories to Self-refresh mode and disable DDRCLK.

41.4. Processor Clock Controller

The PMC features a Processor Clock (CPU_CLK) controller that implements the processor Sleep mode. CPU_CLK can be disabled by executing the WFI (WaitForInterrupt) processor instruction.

CPU_CLK is enabled after a reset and is automatically re-enabled by any enabled interrupt. The processor Sleep mode is entered by disabling CPU_CLK, which is automatically re-enabled by any enabled interrupt, or by the reset of the product.

When processor Sleep mode is entered, the current instruction is finished before the CPU_CLK is stopped, but this does not prevent data transfers from other hosts of the system bus.

The clock selection is done in PMC_CPU_CKR.CSS.

The prescaler is configured in PMC_CPU_CKR.PRES.

© 2026 Microchip Technology Inc. and its subsidiaries

The Processor Clock Controller also generates a main system bus clock, MCK, which is a subdivision of the CPU_CLK.

Only one of CSS, PRES and MDIV fields can be modified at a time. When one of these parameters is modified, no other modification can be performed on these fields as long as the MCKRDY status flag is low.

Any modification in CSS, PRES or MDIV fields must never lead to generate an MCK frequency that is greater than the maximum allowed system frequency. When changing the source clock of the system to a faster clock, the fields must be modified using the following order: MDIV, PRES and then CSS. When changing the source clock of the system to a slower clock, the fields must be modified using the following order: CSS, PRES and then MDIV.

If the destination clock does not exist, the switching is not performed. The CPU_CLK keeps running with the previous clock and the system must be reset to run correctly again.

Note: Among all possible sources of GCLK, PLL(0) cannot be selected. PLL(4) (which is PLL(0) divided by 2) can be selected instead.

41.5. USB Clock Controller

The user can select the PLLA or the UPLL output as the USB source clock by writing PMC_USB.USBS. If using the USB, the user must program the PLL to generate an appropriate frequency depending on PMC_USB.USBDIV.

When the PLL output is stable (the LOCK bit is set), the USB device and host clocks can be enabled by setting the UHP bits in the System Clock Enable register (PMC_SCER). To save power on this peripheral when it is not used, the user can set the UHP bits in the System Clock Disable register (PMC_SCDR). The UHP bits in the System Clock Status register (PMC_SCSR) shows the activity of this clock. The USB device and host ports requires both the 48 MHz signal and the peripheral clock. The USB peripheral clock may be controlled by means of the Peripheral Clock Controller.

41.6. Free-Running Processor Clock

The Free-Running Processor clock (FCLK) used for sampling interrupts and clocking debug blocks ensures that interrupts can be sampled, and sleep events can be traced, while the processor is sleeping.

41.7. Peripheral and Generic Clock Controller

The PMC controls the clocks of the embedded peripherals by means of the Peripheral Control register (PMC_PCR). With this register, the user can enable and disable the different clocks used by the peripherals:

- Peripheral clocks (periph_clk[PID]), routed to every peripheral and derived from MCK. It is mandatory to enable this clock before using a peripheral.
- Generic clocks (GCLK[PID]), routed to selected peripherals only (refer to the “Peripheral Identifiers” table). These clocks are independent of the core and bus clocks (CPU_CLK, MCK and periph_clk[PID]). They are generated by selection and division of available sources. The list of available source clocks depends on the peripheral. Refer to the description of each peripheral to know available sources and limitations to be applied to GCLK[PID] compared to periph_clk[PID].

To configure a peripheral’s clocks, PMC_PCR.CMD must be written to ‘1’ and PMC_PCR.PID must be written with the index of the corresponding peripheral. All other configuration fields must be correctly set.

To read the current clock configuration of a peripheral, PMC_PCR must be first accessed with PMC_PCR.CMD bit written to ‘0’ and PMC_PCR.PID field written with the index of the corresponding peripheral. This write does not modify the configuration of the peripheral. The PMC_PCR can then be read to know the configuration status of the corresponding PID.

The status of the peripheral clock activity can be read in the Peripheral Clock Status registers (PMC_CSRx).

© 2026 Microchip Technology Inc. and its subsidiaries

The status of the peripheral generic clock activity can be read in the Generic Clock Status registers (PMC_GCSRx).

When a peripheral or a generic clock is disabled, it is immediately stopped. These clocks are disabled after a reset. The source and the division ratio of generic clocks must not be modified while the peripheral is enabled. The generic clock configuration must be set before the peripheral is enabled.

To stop a peripheral clock, it is recommended that the system software wait until the peripheral has executed its last programmed operation before disabling the clock. This is to avoid data corruption or erroneous behavior of the system.

41.8. Programmable Clock Output Controller

The PMC controls two signals to be output on the external pins PCKx. Each signal can be independently programmed via the Programmable Clock registers (PMC_PCKx).

PCKx can be independently selected between MD_SLCK, TD_SLCK, MAINCK, MCK and any PLLCK by configuring PMC_PCKx.CSS. Each output signal can also be divided by 1 to 256 by configuring PMC_PCKx.PRES.

Each output signal can be enabled and disabled by writing a '1' to the corresponding bits PMC_SCER.PCKx and PMC_SCDR.PCKx, respectively. The status of the active programmable output clocks is shown in PMC_SCSR.PCKx.

The status flag PMC_SR.PCKRDYx indicates that the clock configured through the PMC_PCKx register is correctly established.

As the Programmable Clock Controller does not manage with glitch prevention when switching clocks, it is strongly recommended to disable PCKx before any configuration change and to re-enable it once the change is performed.

41.9. Ultra-Low Power Mode and Fast Start-Up

The following sections provide a brief description of the Ultra-Low Power mode features of the device as seen from the PMC. A more detailed description, including power consumption and wake-up time figures, can be found in the section "Electrical Characteristics".

41.9.1. ULP1 Mode

When the system is in Ultra-Low Power 1 (ULP1) mode, all clocks of the system except MD_SLCK are stopped. The source clock of all MCKx must be set to the main clock, and the source of the main clock must be set to main RC oscillator.

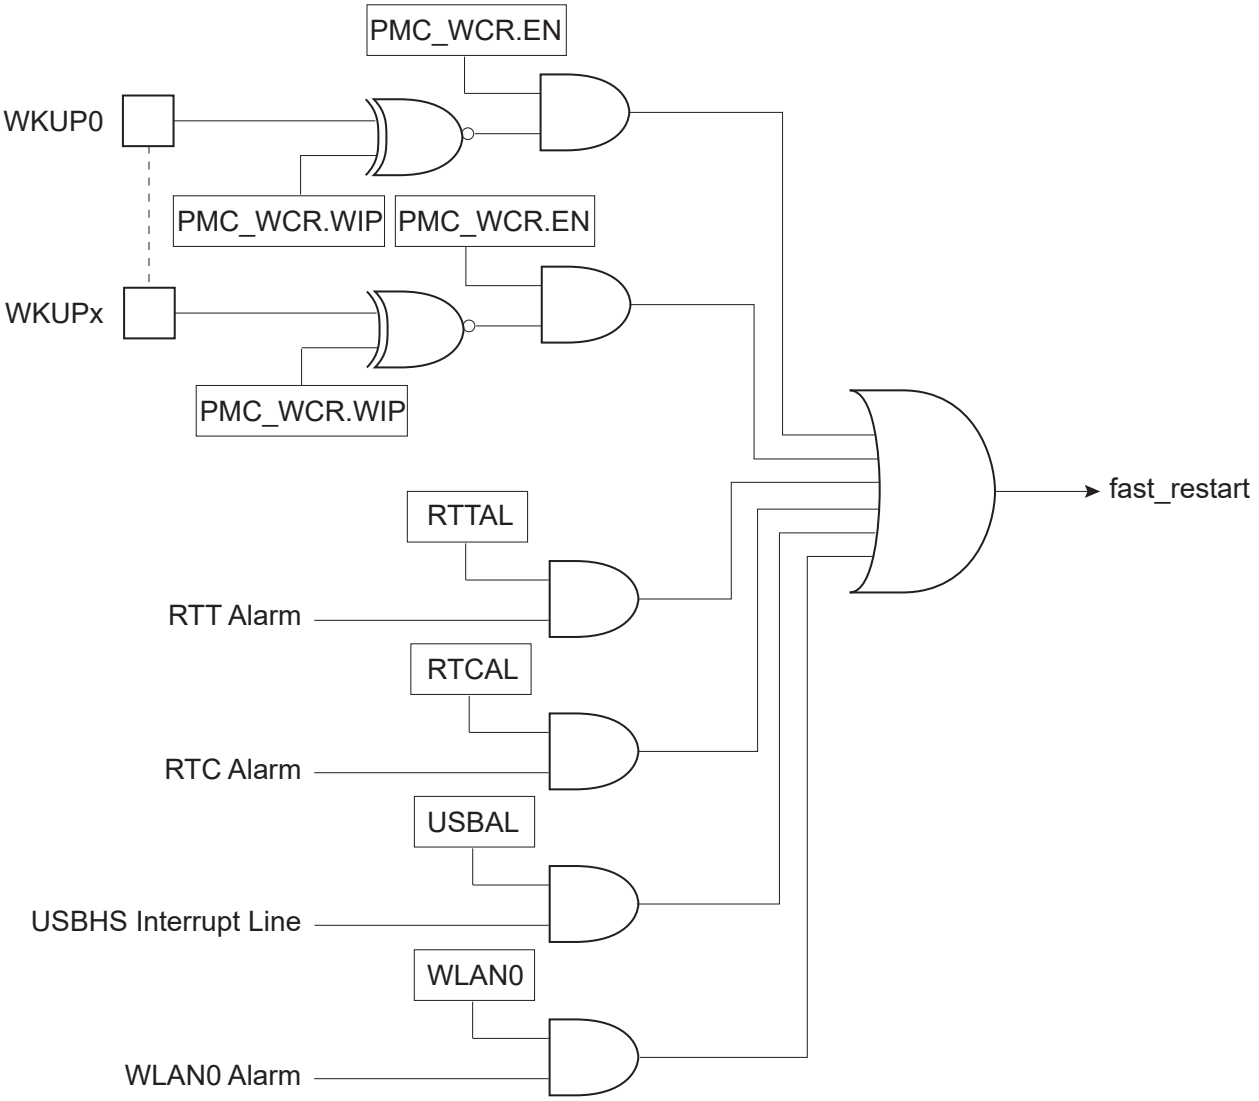
Prior to instructing the device to enter ULP1 mode:

1. Select Main RC as the source of MAINCK by configuring CKGR_MOR.MOSCSEL to '0'.
2. Select MAINCK as the source of MCK by configuring PMC_CPU_CKR.CSS to '1'.
3. Disable the PLL if enabled and disable the main crystal oscillator by setting CKGR_MOR.MOSCXTEN to '0'.
4. Wait for two SLCK clock cycles.
5. Clear the internal wake-up sources.
6. Verify that none of the enabled external wake-up inputs (WKUP) hold an active polarity.

The system enters ULP1 mode by setting CKGR_MOR.ULP1. The PMC registers must not be accessed immediately after this access.

41.9.2. Fast Start-Up

At exit from ULP1 mode, the device allows the processor to restart in several microseconds only if the C-code function that manages the ULP1 mode entry and exit is linked to and executed from on-chip SRAM.



© 2026 Microchip Technology Inc. and its subsidiaries

A fast start-up occurs upon the detection of a programmed level on one of the wake-up inputs (WKUP) or upon an active alarm from the RTC, RTT, USB Controller or Wake-up on LAN 0 alarm. The polarity of each of the wake-up inputs is programmable in the PMC Wake-Up Control Register (PMC_WCR).

WARNING The duration of the WKUPx pins active level must be greater than four MAINCK cycles.

The fast start-up circuitry, as shown in the following figure, is fully asynchronous and provides a fast start-up signal to the PMC. As soon as the fast start-up signal is asserted, the main RC oscillator restarts automatically.

Figure 41.2. Fast Start-Up Circuitry

Each wake-up input pin can be configured to generate a fast start-up event by setting the corresponding bits in PMC_WCR.

To configure a wake-up pin, a write access must be performed in PMC_WCR (CMD='1'). Field PID must be written with the ID of the wake-up pin, WIP set to the polarity of the wake-up pin and EN set to enable/disable the wake-up pin.

© 2026 Microchip Technology Inc. and its subsidiaries

To read the configuration status of a wake-up pin, PMC_WCR.PID must be written with the ID of the wake-up pin and the CMD bit set to ‘0’. Then the next read access to PMC_WCR sends the configuration status of the wake-up pin specified in PID.

Each alarm can be enabled to generate a fast start-up event by setting the corresponding bit in PMC_FSMR.

The user interface does not provide any status for fast start-up. The status can be read in the PIO Controller and the status registers of the RTC, RTT and USB Controller.

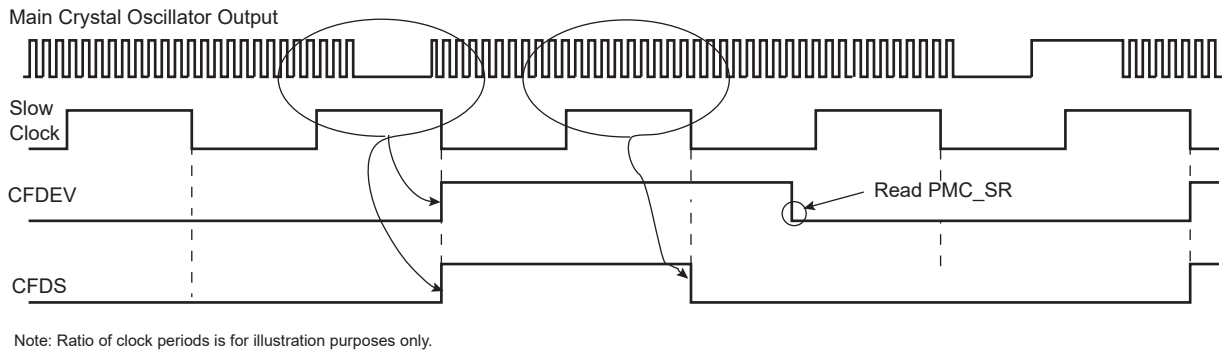
41.10. Main Crystal Oscillator Failure Detection

The main crystal oscillator failure detector monitors the main crystal oscillator against the slow RC oscillator and provides an automatic switchover of the MAINCK source to the main RC oscillator in case of failure detection.

The failure detector can be enabled or disabled by configuring CKGR_MOR.CFDEN. It cannot be enabled if the main crystal oscillator is disabled. It must be disabled before disabling the main crystal oscillator.

It is also disabled in either of the following cases:

- after a VDDCORE reset
- when the main crystal oscillator is disabled (MOSCXTEN = 0)



A failure is detected by means of a counter incrementing on the main crystal oscillator output and detection logic is triggered by the slow RC oscillator which is automatically enabled when CFDEN = 1.

The counter is cleared when the slow RC oscillator clock signal is low and enabled when the signal is high. Thus, the failure detection time is one slow RC oscillator period. If, during the high level period of the slow RC oscillator clock signal, less than eight main crystal oscillator clock periods have been counted, then a failure is reported. Note that when enabling the failure detector, up to two cycles of the slow RC oscillator are needed to detect a failure of the main crystal oscillator.

If a main crystal oscillator failure is detected, PMC_SR.CFDEV and PMC_SR.FOS both indicate a failure event. PMC_SR.CFDEV is cleared on read of PMC_SR, and PMC_SR.FOS is cleared by writing a ‘1’ to the FOCLR bit in the PMC Fault Output Clear register (PMC_FOCR).

Only PMC_SR.CFDEV can generate an interrupt if the corresponding interrupt source is enabled in PMC_IER. The current status of the clock failure detection can be read at any time from PMC_SR.CFDS.

Figure 41.3. Clock Failure Detection Example

Note: Ratio of clock periods is for illustration purposes only.

If the CKGR_MOR.AUTOMAINSW bit is set to'1', the source of MAINCK automatically switches to the MAIN RC oscillator. If the main RC oscillator was previously powered off, it is first powered on before

© 2026 Microchip Technology Inc. and its subsidiaries

switching. If the CKGR_MOR.AUTOCPUSW bit is set to '1', the source of MCK automatically switches to MAINCK.

If the main crystal oscillator is selected as the source of MAINCK, the PMC can be configured to automatically select the main RC oscillator as the source of MAINCK in case of a main crystal oscillator failure detection by setting the CKGR_MOR.AUTOMAINSW to '1'. Additionally, if the source of CPU_CLK is a PLL driven by the main crystal oscillator, the PMC can be configured to automatically select the MAINCK as the source of CPU_CLK in case of a main crystal oscillator failure detection by setting the CKGR_MOR.AUTOCPUSW to '1'. CKGR_MOR.AUTOMAINSW must be set to '1' prior to setting CKGR_MOR.AUTOCPUSW to '1'.

Six slow RC oscillator clock cycles are necessary to detect and switch from the main crystal oscillator to the main RC oscillator.

41.11. 32.768 kHz Crystal Oscillator Frequency Monitor

The frequency of the 32.768 kHz crystal oscillator can be monitored by configuring CKGR_MOR.XT32KFME. Prior to enabling the monitoring, the 32.768 kHz crystal oscillator must be started and its start-up time be elapsed. Refer to the section “Slow Clock Controller (SCKC)” for details on the slow clock generator.

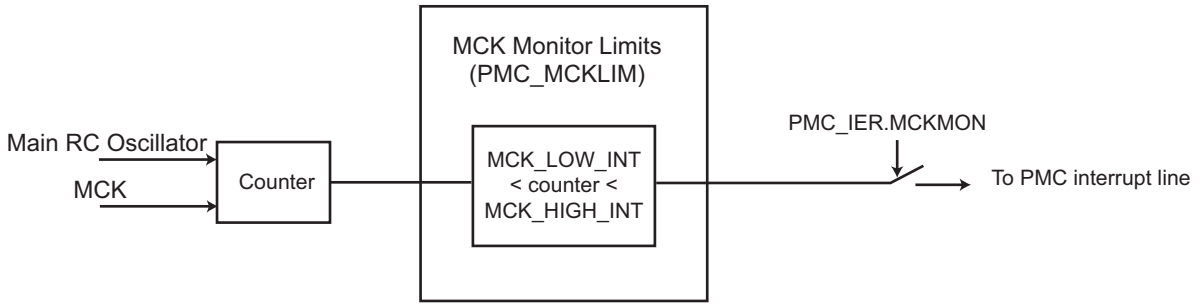
An error flag (PMC_SR.XT32KERR) is asserted when the 32.768 kHz crystal oscillator frequency is out of its nominal frequency value (i.e., 32.768 kHz). The error flag can be cleared only if the monitoring is disabled.

The frequency drift is computed with the main RC oscillator. The permitted drift of the crystal is 10000 ppm (1%), which allows any standard crystal to be used.

The monitored clock frequency is declared invalid if at least four consecutive 32.768 kHz crystal oscillator clock period measurement results are over the nominal period.

The error flag can be defined as an interrupt source of the PMC by setting PMC_IER.XT32KERR. This flag is also routed to the Reset Controller (RSTC) and may generate a reset of the device.

41.12. MCK Frequency Monitor



The frequency of MCK can be monitored with the main RC oscillator. This monitoring can only be performed if the MCK frequency is at least three times faster than the embedded main RC oscillator. This function is enabled by writing a ‘1’ to PMC_IER.MCKMON.

An error on the MCK frequency can lead to a PMC interrupt.

When the corresponding PMC interrupt is enabled, the status of the MCK monitoring can be read on PMC_SR.MCKMON. This status is cleared on read.

Once enabled, the monitor continuously counts the number of MCK cycles within 15 cycles of the embedded main RC oscillator. The result is then compared to threshold values defined in the PMC_MCKLIM register. Two levels of threshold can be defined to generate an interrupt.

Figure 41.4. MCK Frequency Monitor

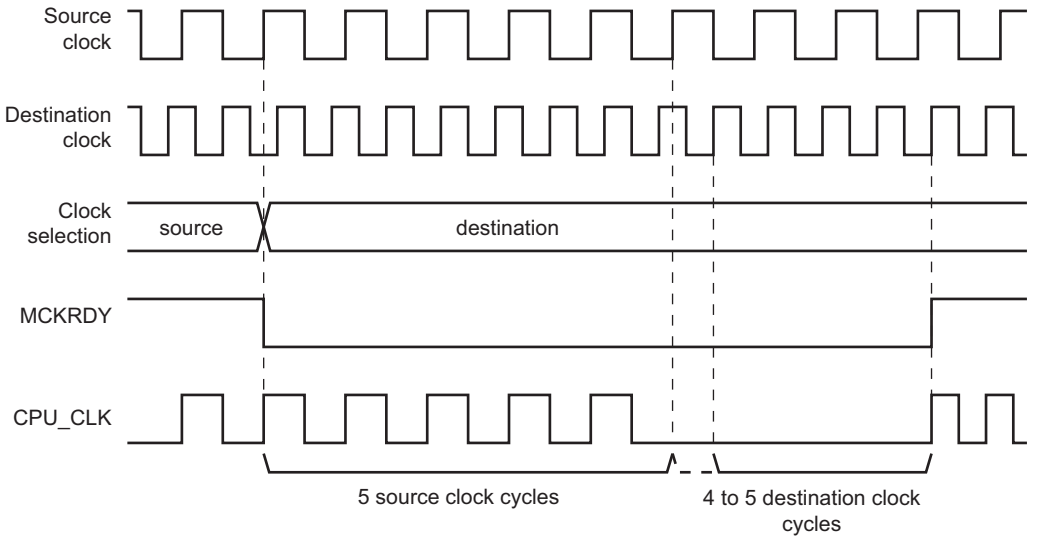
© 2026 Microchip Technology Inc. and its subsidiaries

41.13. Recommended Programming Sequence

Follow the steps below to program the PMC:

1. If the main crystal oscillator is not required, the PLL can be directly configured (step 5) else this oscillator must be started (step 2).
2. Verify the existence and frequency value of the main crystal oscillator following the sequence defined in Main Frequency Counter.
3. If the main crystal oscillator is enabled and valid, the source of MAINCK can be switched to the main crystal oscillator by writing CKGR_MOR.MOSCSEL to 1 else the PLL can be directly configured.
4. Wait for the end of the MAINCK source switching by either polling the MOSCSELS or setting the corresponding interrupt.
5. Configure the PLLs by following the setup defined in Divider and Phase Lock Loop Programming (if not required, proceed to step 6).
6. Configure the MCK division ratio by setting PMC_CPU_CKR.MDIV. Available values are 0, 1, 2, 3, 4. MCK output is the CPU_CLK frequency divided by 1, 2, 3, 4 or 5, depending on the value programmed in MDIV.
   By default, MDIV is cleared, which indicates that the CPU_CLK is equal to MCK.
7. Wait for the end of the MCK ratio switching by either polling the MCKRDY or setting the corresponding interrupt.
8. Select the division ratio of CPU_CLK by setting PMC_CPU_CKR.PRES.
   PRES is used to define the CPU_CLK and MCK prescaler. The user can choose between different values (1, 2, 3, 4, 8, 16, 32, 64). Prescaler output is the selected clock source frequency divided by the PRES value.
9. Wait for the end of the CPU_CLK ratio switching by either polling the MCKRDY or setting the corresponding interrupt.
10. Select the source clock of CPU_CLK by setting PMC_CPU_CKR.CSS.
    CSS is used to select the clock source of MCK and CPU_CLK. By default, the selected clock source is MAINCK.
11. Wait for the end of the CPU_CLK source switching by either polling the MCKRDY or setting the corresponding interrupt.
    PMC_CPU_CKR must not be programmed in a single write operation.
    Reconfiguring MDIV, PRES and CSS fields must always be done by following the right order of operation described above (steps 6 to 11).
12. Configure the programmable clocks (PCKx):
    PCKx are controlled via registers PMC_SCER, PMC_SCDR and PMC_SCSR.
    PCKx can be enabled and/or disabled via PMC_SCER and PMC_SCDR. Two PCKx can be used. PMC_SCSR indicates which PCKx is enabled. By default all PCKx are disabled.
    PMC_PCKx registers are used to configure PCKx as described in Programmable Clock Output Controller.
13. Enable the peripheral and generic clocks.
    Once all of the previous steps have been completed, the peripheral and generic clocks can be configured via register PMC_PCR as described in Peripheral and Generic Clock Controller.

41.14. Clock Switching Details



41.14.1. CPU Clock Switching Timings

The glitch-free clock switcher implemented to control the sources of CPU_CLK and MCK performs clock switching in 5 clock cycles of the currently used clock plus 5 cycles of the target clock.

© 2026 Microchip Technology Inc. and its subsidiaries

The clock switching is effective once MCKRDY rises. See the following figure.

Figure 41.5. Switch CPU Clock (CPU_CLK) from Source Clock to Destination Clock

41.15. Register Write Protection

To prevent any single software error from corrupting PMC behavior, certain registers in the address space can be write-protected by setting the WPEN bit or the WPITEN bit in the PMC Write Protection Mode Register (PMC_WPMR).

If a write access to a write-protected register is detected, the WPVS flag in the PMC Write Protection Status Register (PMC_WPSR) is set and the field WPVSRC indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading the PMC_WPSR.

The following registers are write-protected when the WPEN bit is set in PMC_WPMR:

- PMC System Clock Enable Register
- PMC System Clock Disable Register
- PMC PLL Control Register 0
- PMC PLL Control Register 1
- PMC PLL Spread Spectrum Register
- PMC PLL Analog Control Register
- PMC PLL Update Register
- PMC Clock Generator Main Oscillator Register
- PMC Clock Generator Main Clock Frequency Register
- PMC CPU Clock Register
- PMC USB Clock Register
- PMC Programmable Clock Register
- PMC Fast Start-Up Mode Register
- PMC Wake-Up Control Register
- PMC Peripheral Control Register
- PMC MCK Monitor Limits Register

© 2026 Microchip Technology Inc. and its subsidiaries

The following interrupt registers are write-protected when the WPITEN bit is set in PMC_WPMR:

- PMC Interrupt Enable Register
- PMC Interrupt Disable Register
- PMC PLL Interrupt Enable Register
- PMC PLL Interrupt Disable Register

41.16.3. PMC System Clock Status Register

Name: PMC_SCSR
Offset: 0x0008
Reset: 0x00000001
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
							PCK1	PCK0
Access							R	R
Reset							0	0

Bit	7	6	5	4	3	2	1	0
		UHP				DDRCK		
Access		R				R		
Reset		0				0		

Bits 8, 9 – PCKx Programmable Clock x Output Status

Value	Description
0	The corresponding Programmable Clock output is disabled.
1	The corresponding Programmable Clock output is enabled.

Bit 6 – UHP USB Host OHCI Clocks Status

Value	Description
0	The UHP48M and UHP12M OHCI clocks are disabled.
1	The UHP48M and UHP12M OHCI clocks are enabled.

Bit 2 – DDRCK MPDDRC Clock Status

Value	Description
0	The MPDDRC clock is disabled.
1	The MPDDRC clock is enabled.

© 2026 Microchip Technology Inc. and its subsidiaries

41.16.4. PMC PLL Control Register 0

Name: PMC_PLL_CTRL0
Offset: 0x000C
Reset: 0x00000000
Property: Read/Write

All fields defined here are applied to the PLL defined by the last ID field written in the PMC_PLL_UPDT register.

Bit	31	30	29	28	27	26	25	24
	ENLOCK	ENIOPLLCK	ENPLLCK	ENPLL				
Access	R/W	R/W	R/W	R/W				
Reset	0	0	0	0				

Bit	23	22	21	20	19	18	17	16
					DIVIO[7:4]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	15	14	13	12	11	10	9	8
	DIVIO[3:0]							
Access	R/W	R/W	R/W	R/W				
Reset	0	0	0	0				

Bit	7	6	5	4	3	2	1	0
	DIVPMC[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 31 – ENLOCK Enable PLL Lock

Value	Description
0	The lock signal sent by the PLL is ignored. The PLL is considered as locked once the start-up time defined by PMC_PLL_UPDT.STUPTIM has elapsed.
1	The PLL is considered as locked once the start-up time defined by PMC_PLL_UPDT.STUPTIM has elapsed and the lock signal sent by the PLL has risen.

Bit 30 – ENIOPLLCK Enable PLL Clock for IO

This feature is available for AUDIOPLL only and is configurable only when the DIVIO fied is programmed to 0.

Value	Description
0	The clock generated by the PLL is not sent to the IO.
1	The clock generated by the PLL is sent to the IO.

Bit 29 – ENPLLCK Enable PLL Clock for PMC

This feature is available for all PLLs and is configurable only when the DIVPMC fied is programmed to 0.

Value	Description
0	The clock generated by the PLL is not send to the PMC.
1	The clock generated by the PLL is sent to the PMC.

Bit 28 – ENPLL Enable PLL

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	The PLL is off.
1	The PLL is on.

Bits 19:12 – DIVIO[7:0] Divider for PAD

Specifies the division ratio applied to the internal PLL clock before being sent to the IO. This feature is only available for AUDIOPLL. The frequency is defined by the following formula:

$$f_{\mathrm{IOPLLCK}} = \frac{f_{\mathrm{COREPLLCK}}}{(\mathrm{DIVIO} + 1)}$$

Bits 7:0 – DIVPMC[7:0] Divider for PMC

Specifies the division ratio applied to the internal PLL clock before being sent to the PMC. The frequency is defined by the following formula:

$$f_{\mathrm{PLL\ Clock}} = \frac{f_{\mathrm{COREPLLCK}}}{(\mathrm{DIVPMC} + 1)}$$

For the PLLA, DIVPMC must be lower than or equal to 48 and its value must be different from 10, 12, 16, 18, 21, 22, 25, 26, 28, 30, 31, 32, 33, 36, 37, 38, 39, 40, 42, 43, 44, 45, 46 and 47.

© 2026 Microchip Technology Inc. and its subsidiaries

41.16.5. PMC PLL Control Register 1

Name: PMC_PLL_CTRL1
Offset: 0x0010
Reset: 0x00000000
Property: Read/Write

All fields defined here are applied to the PLL defined by the last ID field written in the PMC_PLL_UPDT register.

Bit	31	30	29	28	27	26	25	24
	MUL[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:24 – MUL[7:0] Multiplier Factor Value
Configures the internal clock frequency. See Divider and Phase Lock Loop Programming.

Bits 21:0 – FRACR[21:0] Fractional Loop Divider Setting

© 2026 Microchip Technology Inc. and its subsidiaries

41.16.6. PMC PLL Spread Spectrum Register

Name: PMC_PLL_SSR
Offset: 0x0014
Reset: 0x00000000
Property: Read/Write

All fields defined here are applied to the PLL defined by the last ID field written in the PMC_PLL_UPDT register.

Bit	31	30	29	28	27	26	25	24
				ENSPREAD				
Access				R/W				
Reset				0				

Bit	23	22	21	20	19	18	17	16
	NSTEP[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	STEP[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 28 – ENSPREAD Spread Spectrum Enable

Value	Description
0	The spread spectrum is not applied to the PLL.
1	The spread spectrum is applied to the PLL.

Bits 23:16 – NSTEP[7:0] Spread Spectrum Number of Steps
Specifies how many times STEP is applied to the PLL ratio. The value of NSTEP must be equal to or greater than 1.

Bits 15:0 – STEP[15:0] Spread Spectrum Step Size
When the spread spectrum is active, this field defines the step size that will be applied the PMC_PLL_CTRL1.FRACR factor. The step is applied on the LSB of PMC_PLL_CTRL1.FRACR.

© 2026 Microchip Technology Inc. and its subsidiaries

41.16.7. PMC PLL Analog Control Register

Name: PMC_PLL_ACR
Offset: 0x0018
Reset: 0x00020033
Property: Read/Write

This register must be loaded with the recommended values described in the Electrical Characteristics section.

All fields defined here are applied to the PLL defined by the last ID field written in the PMC_PLL_UPDT register.

Bit	31	30	29	28	27	26	25	24
			LOOP_FILTER[5:0]					
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
						LOCK_THR[2:0]		
Access						R/W	R/W	R/W
Reset						0	1	0

Bit	15	14	13	12	11	10	9	8
			UTMIBG	UTMIVR	CONTROL[11:8]			
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	CONTROL[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	1	1	0	0	1	1

Bits 29:24 – LOOP_FILTER[5:0] Loop Filter Selection

Bits 18:16 – LOCK_THR[2:0] PLL Lock Threshold Value Selection

Bit 13 – UTMIBG UPLL Bandgap Control
This bit has no effect when applied to PLLA.

Value	Description
0	The UPLL bandgap is switched off.
1	The UPLL bandgap is switched on.

Bit 12 – UTMIVR UPLL Voltage Regulator Control
This bit has no effect when applied to PLLA.

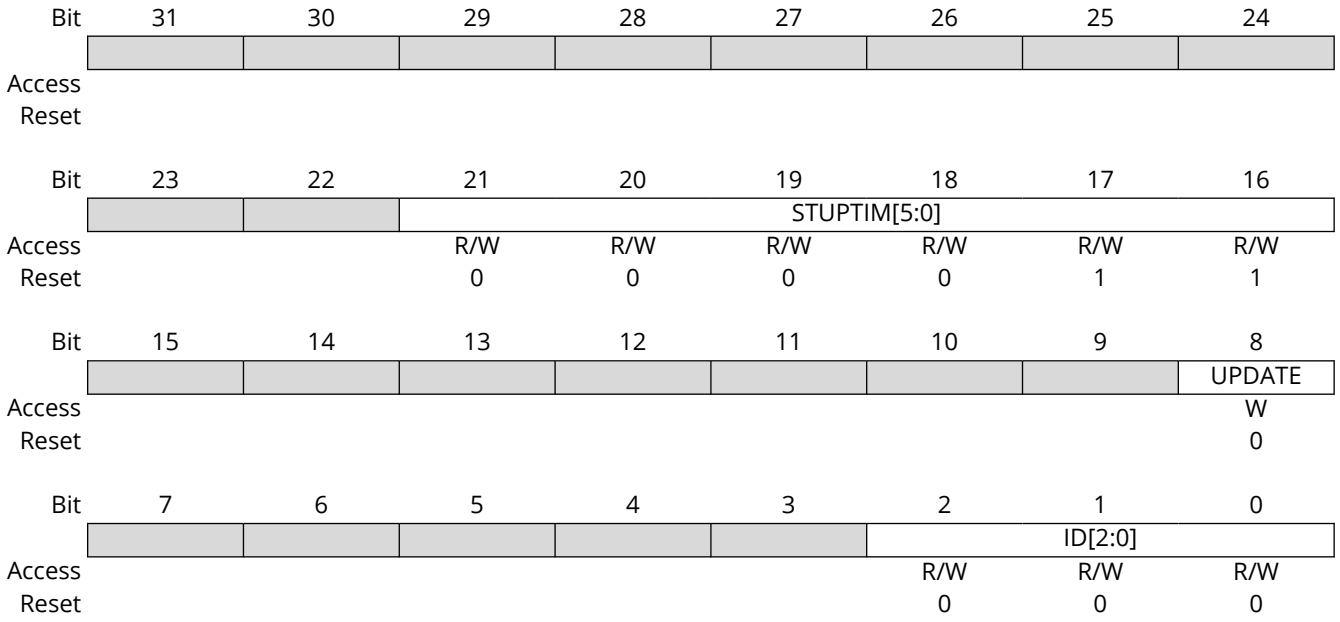
Value	Description
0	The UPLL voltage regulator is switched off.
1	The UPLL voltage regulator is switched on.

Bits 11:0 – CONTROL[11:0] PLL CONTROL Value Selection
On PLLA, this field controls the DCO analog filters:

Field	Description
CONTROL[1:0]	Analog VCO filter selection

© 2026 Microchip Technology Inc. and its subsidiaries

CONTROL (continued)	
Field	**Description**
CONTROL[4:2]	Process configuration
CONTROL[6:5]	VCO gain configuration
CONTROL[7]	Offset frequency adjustment
CONTROL[8]	External pad connection
CONTROL[9]	Test mode dedicated
CONTROL[10]	DAC mode
CONTROL[11]	Enable output phases



On UPLL, this field controls the following PLL ports:

Field	Description
CONTROL[1:0]	Not used
CONTROL[4:2]	Process configuration
CONTROL[6:5]	VCO gain configuration
CONTROL[7]	Offset frequency adjustment
CONTROL[11:8]	Not used

© 2026 Microchip Technology Inc. and its subsidiaries

41.16.8. PMC PLL Update Register

Name: PMC_PLL_UPDT
Offset: 0x001C
Reset: 0x00030000
Property: Read/Write

Bits 21:16 – STUPTIM[5:0] Start-up Time
The start-up time is defined as a number of MD_SLCK cycles and is the same for all PLLs.
STUPTIM can be modified only if all PLLs are off.

Value	Description
0	Only the lock of the PLL is considered to know the lock status of the PLL. If the lock of the PLL is not enabled, the lock never rises.
Other values	If PMC_PLL_CTRL0.ENLOCK is low, specifies the start-up time of the PLL. If PMC_PLL_CTRL0.ENLOCK is high, specifies how long the LOCK signal of the PLL is masked before being read.

Bit 8 – UPDATE PLL Setting Update (write-only)

Value	Description
0	No effect.
1	The PLL configuration written in PMC_PLL_CTRL0 and PMC_PLL_CTRL1 are applied to the PLL defined by the last ID written in the PMC_PLL_CTRL0 register.

Bits 2:0 – ID[2:0] PLL ID
When writing a PLL control register (PMC_PLL_CTRLx), this ID specifies which PLL is impacted by written fields.
When reading a PLL control register (PMC_PLL_CTRLx), this ID specifies which PLL fields are read.

Index	PLL Name	Clock Name	PLL Clock Source	Usage Example
0	PLLA	PLLACK	MAINCK	CPU_CLK and MCK clock sources
1	UPLL	ULLCK	MAIN XTAL OSC	UTMI clock source
2	AUDIOPLL	AUDIOPLLCK	MAIN XTAL OSC	AUDIOCLK output clock source
3	LVDSPLL	LVDSPLLCK	MAIN XTAL OSC	LVDS clock source

© 2026 Microchip Technology Inc. and its subsidiaries

ID (continued)				
Index	**PLL Name**	**Clock Name**	**PLL Clock Source**	**Usage Example**
4	PLLA	PLLADIV2CK	MAINCK	This clock is PLLA divided by 2. Usage: GCLK source

© 2026 Microchip Technology Inc. and its subsidiaries

41.16.9. PMC Clock Generator Main Oscillator Register

Name: CKGR_MOR
Offset: 0x0020
Reset: 0x00000028
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PMC Write Protection Mode Register.
Note: Bit 5 is always read at 1.

Bit	31	30	29	28	27	26	25	24
		AUTOCPUSW	AUTOMAINSW			XT32KFME	CFDEN	MOSCSEL
Access		R/W	R/W			R/W	R/W	R/W
Reset		0	0			0	0	0

Bit	23	22	21	20	19	18	17	16
	KEY[7:0]							
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	MOSCXTST[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
					MOSCRCEN	ULP1		MOSCXTEN
Access					R/W	W		R/W
Reset					1	0		0

Bit 30 – AUTOCPUSW Automatic Processor Clock Source Switching

Value	Description
0	A main crystal oscillator failure detection has no effect on the processor clock source selection.
1	If a main crystal oscillator failure is detected, the processor clock source selection automatically switches to the main clock.

Bit 29 – AUTOMAINSW Automatic Main Clock Source Switching

Value	Description
0	A main crystal oscillator failure detection has no effect on the main clock source selection.
1	If a main crystal oscillator failure is detected, the main clock source selection automatically switches to the main RC.

Bit 26 – XT32KFME 32.768 kHz Crystal Oscillator Frequency Monitoring Enable

Value	Description
0	The 32.768 kHz crystal oscillator frequency monitoring is disabled.
1	The 32.768 kHz crystal oscillator frequency monitoring is enabled.

Bit 25 – CFDEN Clock Failure Detector Enable

Value	Description
0	The clock failure detector is disabled.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	The clock failure detector is enabled.

Bit 24 – MOSCSEL Main Clock Oscillator Selection

Value	Description
0	The main RC oscillator is selected.
1	The main crystal oscillator is selected.

Bits 23:16 – KEY[7:0] Write Access Password

Value	Name	Description
0x37	PASSWD	Writing any other value in this field aborts the write operation. Always reads as 0.

Bits 15:8 – MOSCXTST[7:0] Main Crystal Oscillator Start-up Time

Specifies the number of MD_SLCK cycles multiplied by 8 for the main crystal oscillator start-up time.

Bit 3 – MOSCRCEN Main RC Oscillator Enable

When MOSCRCEN is set, the MOSCRCS flag is set once the main RC oscillator start-up time is achieved.

Value	Description
0	The main RC oscillator is disabled.
1	The main RC oscillator is enabled.

Bit 2 – ULP1 ULP1 Mode Command (write-only)

Value	Description
0	No effect.
1	Puts the device in ULP1 mode.

Bit 0 – MOSCXTEN Main Crystal Oscillator Enable

A crystal must be connected between XIN and XOUT or a clock signal must be provided on XIN with XOUT grounded.

When MOSCXTEN is set, the MOSCXTS flag is set once the main crystal oscillator start-up time is achieved.

Value	Description
0	The main crystal oscillator is disabled.
1	The main crystal oscillator is enabled or in bypass.

© 2026 Microchip Technology Inc. and its subsidiaries

41.16.10.PMC Clock Generator Main Clock Frequency Register

Name: CKGR_MCFR
Offset: 0x0024
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PMC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
								CCSS
Access								R/W
Reset								0

Bit	23	22	21	20	19	18	17	16
				RCMEAS				MAINFRDY
Access				W				R/W
Reset				0				0

Bit	15	14	13	12	11	10	9	8
	MAINF[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	MAINF[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 24 – CCSS Counter Clock Source Selection

Value	Description
0	The measured clock of the MAINF counter is the main RC oscillator.
1	The measured clock of the MAINF counter is the main crystal oscillator.

Bit 20 – RCMEAS RC Oscillator Frequency Measure (write-only)
The measurement is performed on the main frequency (i.e., not limited to the main RC oscillator only). If the source of MAINCK is the main crystal oscillator, the restart of measurement may not be required because of the stability of crystal oscillators.

Value	Description
0	No effect.
1	Restarts measuring of the frequency of MAINCK. MAINF carries the new frequency as soon as a low-to-high transition occurs on the MAINFRDY flag.

Bit 16 – MAINFRDY Main Clock Frequency Measure Ready
To ensure that a correct value is read on the MAINF field, the MAINFRDY flag must be read at '1' then another read access must be performed on the register to get a stable value on the MAINF field.

Value	Description
0	The MAINF value is not valid or the measured oscillator is disabled or a measure has just been started by means of RCMEAS.
1	The measured oscillator has been enabled previously and the MAINF value is available.

© 2026 Microchip Technology Inc. and its subsidiaries

Bits 15:0 – MAINF[15:0] Main Clock Frequency

Provides the number of cycles of the clock selected by the bit CCSS within 16 MD_SLCK periods. To calculate the frequency of the measured clock:

$f_{SELCLK} = (MAINF \times f_{MD_SLCK})/16$

where frequency is in MHz.

© 2026 Microchip Technology Inc. and its subsidiaries

41.16.11.PMC CPU Clock Register

Name: PMC_CPU_CKR
Offset: 0x0028
Reset: 0x00000001
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the PMC Write Protection Mode Register.

The CSS, PRES and MDIV fields cannot be modified simultaneously. If more than one field modification is required, proceed sequentially: modify the first field and wait for PMC_SR.MCKRDY high, then modify the second field and wait for PMC_SR.MCKRDY high, etc.

Bit	7	6	5	4	3	2	1	0
					MCKRDY			MOSCXTS
Access					R			R
Reset					1			0

Bit 25 – PLL_INT PLL Interrupt Status

Value	Description
0	No PLL interrupt has occurred.
1	A PLL interrupt has occurred. PLL interrupt is defined by the configuration of PMC_IMR.

Bit 24 – GCLKRDY GCLK Ready

Value	Description
0	A GCLK is not ready to use (clock switching in progress).
1	All GCLKs are switched to their selected source clock and ready to use.

Bit 23 – MCKMON Main System Bus Clock Clock Monitor Error
This status is cleared on read.

Value	Description
0	Main system bus clock is correct or the CPU clock monitor is disabled.
1	Main system bus clock is incorrect or has been incorrect for an elapsed period of time since the monitoring has been enabled.

Bit 21 – XT32KERR Slow Crystal Oscillator Error

Value	Description
0	The frequency of the 32.768 kHz crystal oscillator is correct (32.768 kHz ±1%) or the monitoring is disabled.
1	The frequency of the 32.768 kHz crystal oscillator is incorrect or has been incorrect for an elapsed period of time since the monitoring has been enabled.

Bit 20 – FOS Clock Failure Detector Fault Output Status

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	The fault output of the clock failure detector is inactive.
1	The fault output of the clock failure detector is active. This status is cleared by writing a '1' to FOCLR in PMC_FOCR.

Bit 19 – CFDS Clock Failure Detector Status

Value	Description
0	A clock failure of the main crystal oscillator clock is not detected.
1	A clock failure of the main crystal oscillator clock is detected.

Bit 18 – CFDEV Clock Failure Detector Event

Value	Description
0	No clock failure detection of the main crystal oscillator clock has occurred since the last read of PMC_SR.
1	At least one clock failure detection of the main crystal oscillator clock has occurred since the last read of PMC_SR.

Bit 17 – MOSCRCS Main RC Oscillator Status

Value	Description
0	The main RC oscillator is not stabilized.
1	The main RC oscillator is stabilized.

Bit 16 – MOSCSELS Main Clock Source Oscillator Selection Status

Value	Description
0	Selection is in progress.
1	Selection is done.

Bits 8, 9 – PCKRDYx Programmable Clock Ready Status

Value	Description
0	Programmable clock x is not ready.
1	Programmable clock x is ready.

Bit 3 – MCKRDY Main System Bus Clock Status

Value	Description
0	Main system bus clock is not ready.
1	Main system bus clock is ready.

Bit 0 – MOSCXTS Main Crystal Oscillator Status

Value	Description
0	The main crystal oscillator is not stabilized.
1	The main crystal oscillator is stabilized.

Bit 24 – WLAN0 Wake-Up on LAN[x] Enable

Value	Description
0	The Wake-up on LAN[x] alarm has no effect on the PMC.
1	The Wake-up on LAN[x] alarm enables a fast restart signal to the PMC.

Bit 18 – USBAL USB Alarm Enable

Value	Description
0	The USB alarm has no effect on the PMC.
1	The USB alarm enables a fast restart signal to the PMC.

Bit 17 – RTCAL RTC Alarm Enable

Value	Description
0	The RTC alarm has no effect on the PMC.
1	The RTC alarm enables a fast restart signal to the PMC.

Bit 16 – RTTAL RTT Alarm Enable

Value	Description
0	The RTT alarm has no effect on the PMC.
1	The RTT alarm enables a fast restart signal to the PMC.

Bit 24 – CMD Command

Value	Description
0	Read mode.
1	Write mode.

Bit 17 – WIP Wake-Up Input Polarity

Defines the active polarity of the selected wake-up input. If the corresponding wake-up input is enabled at the WIP level, it enables a fast restart signal.

Value	Description
0	Active polarity is low.
1	Active polarity is high.

Bit 16 – EN Wake-Up Input Enable

Value	Description
0	The selected wake-up input has no effect on the PMC.
1	The selected wake-up input enables a fast restart signal to the PMC.

Bits 3:0 – WKPIONB[3:0] Wake-Up Input Number

Defines which wake-up source is to be modified during a write access (CMD is set to '1') or which wake-up source status is read on the next read access to this register (CMD is set to '0').

Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
							WPITEN	WPEN
Access							R/W	R/W
Reset							0	0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x504D43	PASSWD	Writing any other value in this field aborts the write operation of the WPEN bit. Always reads as 0.

Bit 1 – WPITEN Write Protection Interrupt Enable

See Register Write Protection for the list of registers that can be write-protected.

Value	Description
0	Disables the write protection on interrupt registers if WPKEY corresponds to 0x504D43 (“PMC” in ASCII).
1	Enables the write protection on interrupt registers if WPKEY corresponds to 0x504D43 (“PMC” in ASCII).

Bit 0 – WPEN Write Protection Enable

See Register Write Protection for the list of registers that can be write-protected.

Value	Description
0	Disables the write protection if WPKEY corresponds to 0x504D43 (“PMC” in ASCII).
1	Enables the write protection if WPKEY corresponds to 0x504D43 (“PMC” in ASCII).

Bit	7	6	5	4	3	2	1	0
								WPVS
Access								R
Reset								0

Bits 23:8 – WPVSRC[15:0] Write Protection Violation Source
When WPVS = 1, WPVSRC indicates the register address offset at which a write access has been attempted.

Bit 0 – WPVS Write Protection Violation Status

Value	Description
0	No write protection violation has occurred since the last read of the PMC_WPSR.
1	A write protection violation has occurred since the last read of the PMC_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSRC.

Access		R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset		0	0	0	0	0	0	0

Bit 31 – CMD Command

Value	Description
0	Read mode.
1	Write mode.

Bit 29 – GCLKEN Generic Clock Enable

Value	Description
0	The selected generic clock is disabled.
1	The selected generic clock is enabled.

Bit 28 – EN Enable

Value	Description
0	The selected peripheral clock is disabled.
1	The selected peripheral clock is enabled.

Bits 27:20 – GCLKDIV[7:0] Generic Clock Division Ratio
Generic clock is the selected clock period divided by GCLKDIV + 1.
GCLKDIV must not be changed while the peripheral selects GCLKx (bit rate, etc.).

Bits 12:8 – GCLKCSS[4:0] Generic Clock Source Selection

Value	Name	Description
0	MD_CLK	MD_SLCK is selected.
1	TD_CLOCK	TD_SLCK is selected.
2	MAINCK	MAINCK is selected.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
3	MCK	MCK is selected.
4	–	Reserved
5	UPLLCK	UPLLCK is selected.
6	AUDIOPLLCK	AUDIOPLLCK is selected.
7	–	Reserved
8	PLLADIV2CLK	PLLADIV2CLK is selected.

Bits 6:0 – PID[6:0] Peripheral ID
Peripheral ID selection.
Not all GCLK inputs are available on all peripherals.
Refer to identifier definitions in the table “Peripheral Identifiers”.

© 2026 Microchip Technology Inc. and its subsidiaries

41.16.24.PMC MCK Monitor Limits Register

Name: PMC_MCKLIM
Offset: 0x009C
Reset: 0x00000000
Property: Read/Write

Reset	0	0	0	0	0	0	0	0

Bits 15:8 – MCK_HIGH_IT[7:0] MCK Monitoring High IT Limit
Beyond this limit, the MCK frequency monitor generates an interrupt.

Bits 7:0 – MCK_LOW_IT[7:0] MCK Monitoring Low IT Limit
Below this limit, the MCK frequency monitor generates an interrupt.

42. Parallel Input/Output Controller (PIO)

42.1. Description

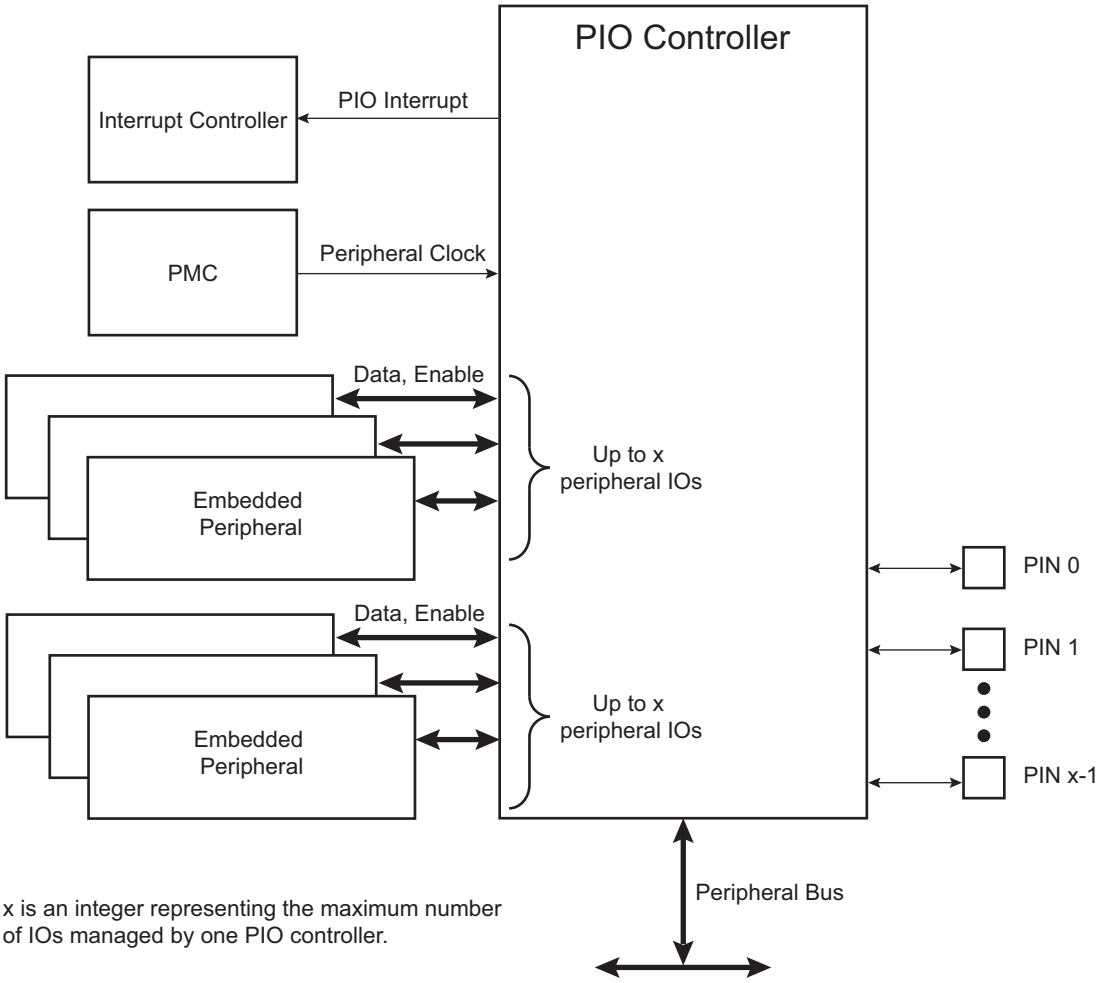
The Parallel Input/Output Controller (PIO) manages up to 32 fully programmable input/output lines. Each I/O line may be dedicated as a general-purpose I/O or be assigned to a function of an embedded peripheral. This ensures effective optimization of the pins of the product.

Each I/O line is associated with a bit number in all of the 32-bit registers of the 32-bit wide user interface.

Each I/O line of the PIO Controller features the following:

- An input change interrupt enabling level change detection on any I/O line
- Additional Interrupt modes enabling rising edge, falling edge, low-level or high-level detection on any I/O line
- A glitch filter providing rejection of glitches lower than one-half of peripheral clock cycle
- A debouncing filter providing rejection of unwanted pulses from key or push button operations
- Multi-drive capability similar to an open drain I/O line
- Control of the I/O line pull-up and pull-down
- Input visibility and output control

The PIO Controller also features a synchronous output providing up to 32 bits of data output in a single write operation.



42.2. Embedded Characteristics

- Up to 32 Programmable I/O Lines
- Fully Programmable through Set/Clear Registers
- Multiplexing of Four Peripheral Functions per I/O Line
- For each I/O Line (Whether Assigned to a Peripheral or Used as General Purpose I/O)
  - Input change interrupt
  - Programmable glitch filter
  - Programmable debouncing filter
  - Multi-drive option enables driving in open drain
  - Programmable pull-up on each I/O line
  - Pin Data Status register provides visibility of the level on the pin at any time
  - Additional interrupt modes on a programmable event: Rising Edge, Falling Edge, Low-Level or High-Level
- Synchronous Output, Provides Set and Clear of Several I/O Lines in a Single Write
- Register Write Protection
- Programmable Schmitt Trigger Inputs
- Programmable Slewrate per I/O Line
- Programmable I/O Drive

© 2026 Microchip Technology Inc. and its subsidiaries

42.3. Block Diagram

Figure 42.1. Block Diagram

42.4. Product Dependencies

42.4.1. Pin Multiplexing

Each pin is configurable, depending on the product, as either a general-purpose I/O line only, or as an I/O line multiplexed with one or two peripheral I/Os. As the multiplexing is hardware defined and thus product-dependent, the hardware designer and programmer must carefully determine the configuration of the PIO Controllers required by their application. When an I/O line is general-purpose only, i.e., not multiplexed with any peripheral I/O, programming of the PIO Controller regarding the assignment to a peripheral has no effect and only the PIO Controller can control how the pin is driven by the product.

42.4.2. External Interrupt Lines

The interrupt signals FIQ and IRQ0 to IRQn are generally multiplexed through the PIO Controllers. However, it is not necessary to assign the I/O line to the interrupt function as the PIO Controller has no effect on inputs and the external interrupt lines are used only as inputs.

© 2026 Microchip Technology Inc. and its subsidiaries

42.4.3. Power Management

The Power Management Controller controls the peripheral clock in order to save power. Writing any of the registers of the user interface does not require the peripheral clock to be enabled. This means that the configuration of the I/O lines does not require the peripheral clock to be enabled.

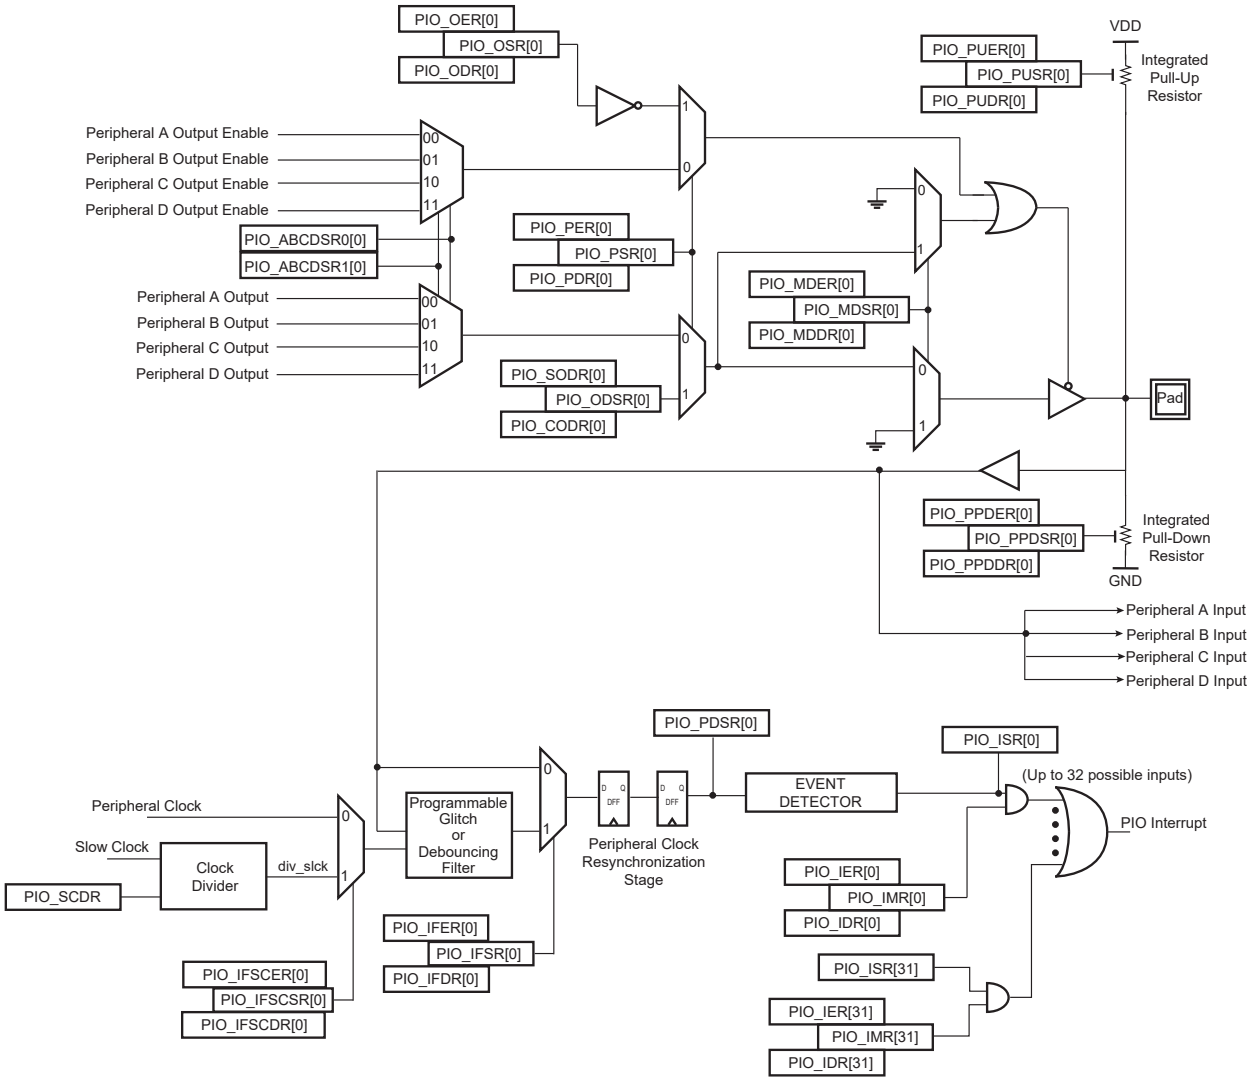
However, when the clock is disabled, not all of the features of the PIO Controller are available, including glitch filtering. Note that the input change interrupt, the interrupt modes on a programmable event and the read of the pin level require the clock to be validated.

After a hardware reset, the peripheral clock is disabled by default.

The user must configure the Power Management Controller before any access to the input line information.

42.4.4. Interrupt Sources

For interrupt handling, the PIO Controllers are considered as user peripherals. This means that the PIO Controller interrupt lines are connected among the interrupt sources. Refer to the PIO Controller peripheral identifier in the Peripheral Identifiers table to identify the interrupt sources dedicated to the PIO Controllers. Using the PIO Controller requires the Interrupt Controller to be programmed first.



The PIO Controller interrupt can be generated only if the peripheral clock is enabled.

42.5. Functional Description

The PIO Controller features up to 32 fully-programmable I/O lines. Most of the control logic associated to each I/O is represented in the following figure. In this description each signal shown represents one of up to 32 possible indexes.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 42.2. I/O Line Control Logic

42.5.1. Pull-up and Purell-down Resistor Control

Each I/O line is designed with an embedded pull-up resistor and an embedded pull-down resistor. The pull-up resistor can be enabled or disabled by writing to the Pull-Up Enable register (PIO_PUER) or Pull-Up Disable register (PIO_PUDR), respectively. Writing to these registers results in setting or clearing the corresponding bit in the Pull-Up Status register (PIO_PUSR). Reading a one in PIO_PUSR means the pull-up is disabled and reading a zero means the pull-up is enabled. The pull-down resistor can be enabled or disabled by writing the Pull-Down Enable register (PIO_PPDER) or the Pull-Down Disable register (PIO_PPDDR), respectively. Writing in these registers results in setting or clearing the corresponding bit in the Pull-Down Status register (PIO_PPDSR). Reading a one in PIO_PPDSR means the pull-up is disabled and reading a zero means the pull-down is enabled.

Enabling the pull-down resistor while the pull-up resistor is still enabled is not possible. In this case, the write of PIO_PPDER for the relevant I/O line is discarded. Likewise, enabling the pull-up resistor while the pull-down resistor is still enabled is not possible. In this case, the write of PIO_PUER for the relevant I/O line is discarded.

Control of the pull-up resistor is possible regardless of the configuration of the I/O line.

After reset, depending on the I/O, pull-up or pull-down can be set.

© 2026 Microchip Technology Inc. and its subsidiaries

42.5.2. I/O Line or Peripheral Function Selection

When a pin is multiplexed with one or two peripheral functions, the selection is controlled with the Enable register (PIO_PER) and the Disable register (PIO_PDR). The Status register (PIO_PSR) is the result of the set and clear registers and indicates whether the pin is controlled by the corresponding peripheral or by the PIO Controller. A value of zero indicates that the pin is controlled by the corresponding on-chip peripheral selected in the Peripheral ABCD Select registers (PIO_ABCDSR0 and PIO_ABCDSR1). A value of one indicates the pin is controlled by the PIO Controller.

If a pin is used as a general-purpose I/O line (not multiplexed with an on-chip peripheral), PIO_PER and PIO_PDR have no effect and PIO_PSR returns a one for the corresponding bit.

After reset, the I/O lines are controlled by the PIO Controller, i.e., PIO_PSR resets at one. However, in some events, it is important that PIO lines are controlled by the peripheral (as in the case of memory chip select lines that must be driven inactive after reset, or for address lines that must be driven low for booting out of an external memory). Thus, the reset value of PIO_PSR is defined at the product level and depends on the multiplexing of the device.

42.5.3. Peripheral A or B or C or D Selection

The PIO Controller provides multiplexing of up to four peripheral functions on a single pin. The selection is performed by writing PIO_ABCDSR0 and PIO_ABCDSR1.

For each pin:

- The corresponding bit at level zero in PIO_ABCDSR0 and the corresponding bit at level zero in PIO_ABCDSR1 means peripheral A is selected.
- The corresponding bit at level one in PIO_ABCDSR0 and the corresponding bit at level zero in PIO_ABCDSR1 means peripheral B is selected.
- The corresponding bit at level zero in PIO_ABCDSR0 and the corresponding bit at level one in PIO_ABCDSR1 means peripheral C is selected.
- The corresponding bit at level one in PIO_ABCDSR0 and the corresponding bit at level one in PIO_ABCDSR1 means peripheral D is selected.

Note that multiplexing of peripheral lines A, B, C and D only affects the output line. The peripheral input lines are always connected to the pin input (see the figure I/O Line Control Logic).

Writing in PIO_ABCDSR0 and PIO_ABCDSR1 manages the multiplexing regardless of the configuration of the pin. However, assignment of a pin to a peripheral function requires a write in PIO_ABCDSR0 and PIO_ABCDSR1 in addition to a write in PIO_PDR.

After reset, PIO_ABCDSR0 and PIO_ABCDSR1 are zero, thus indicating that all the PIO lines are configured on peripheral A. However, peripheral A generally does not drive the pin as the PIO Controller resets in I/O Line mode.

If the software selects a peripheral A, B, C or D which does not exist for a pin, no alternate functions are enabled for this pin and the selection is taken into account. The PIO Controller does not carry out checks to prevent selection of a peripheral which does not exist.

42.5.4. Output Control

When the I/O line is assigned to a peripheral function, i.e., the corresponding bit in PIO_PSR is at zero, the drive of the I/O line is controlled by the peripheral. Peripheral A or B or C or D depending on the value in PIO_ABCDSR0 and PIO_ABCDSR1 determines whether the pin is driven or not.

When the I/O line is controlled by the PIO Controller, the pin can be configured to be driven. This is done by writing the Output Enable register (PIO_OER) and Output Disable register (PIO_ODR). The results of these write operations are detected in the Output Status register (PIO_OSR). When a bit in this register is at zero, the corresponding I/O line is used as an input only. When the bit is at one, the corresponding I/O line is driven by the PIO Controller.

© 2026 Microchip Technology Inc. and its subsidiaries

The level driven on an I/O line can be determined by writing in the Set Output Data register (PIO_SODR) and the Clear Output Data register (PIO_CODR). These write operations, respectively, set and clear the Output Data Status register (PIO_ODSR), which represents the data driven on the I/O lines. Writing in PIO_OER and PIO_ODR manages PIO_OSR whether the pin is configured to be controlled by the PIO Controller or assigned to a peripheral function. This enables configuration of the I/O line prior to setting it to be managed by the PIO Controller.

Similarly, writing in PIO_SODR and PIO_CODR affects PIO_ODSR. This is important as it defines the first level driven on the I/O line.

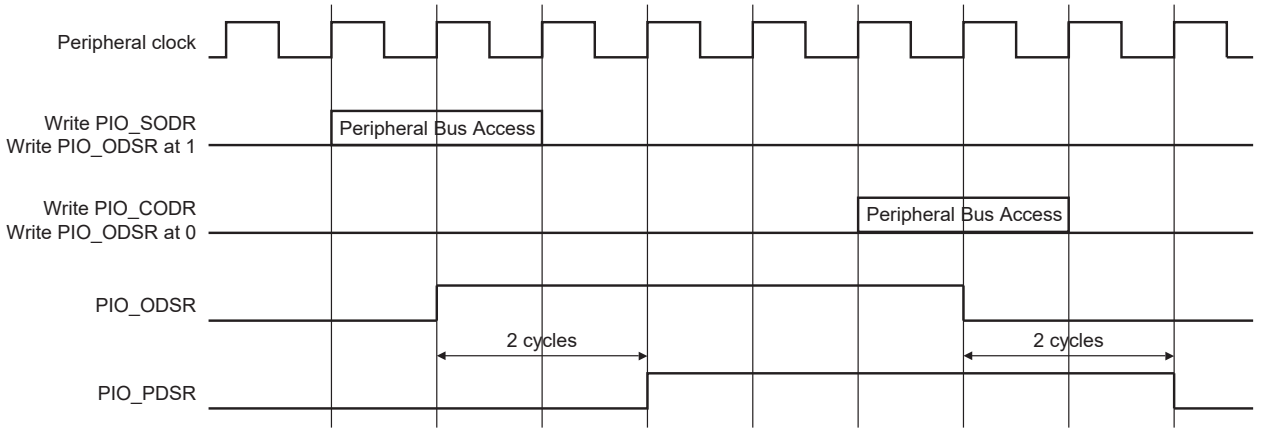
42.5.5. Synchronous Data Output

Clearing one or more PIO line(s) and setting another one or more PIO line(s) synchronously cannot be done by using PIO_SODR and PIO_CODR. It requires two successive write operations into two different registers. To overcome this, the PIO Controller offers a direct control of PIO outputs by single write access to PIO_ODSR. Only bits unmasked by the Output Write Status register (PIO_OWSR) are written. The mask bits in PIO_OWSR are set by writing to the Output Write Enable register (PIO_OWER) and cleared by writing to the Output Write Disable register (PIO_OWDR).

After reset, the synchronous data output is disabled on all the I/O lines as PIO_OWSR resets at 0x0.

42.5.6. Multi-Drive Control (Open Drain)

Each I/O can be independently programmed in open drain by using the multi-drive feature. This feature permits several drivers to be connected on the I/O line which is driven low only by each device. An external pull-up resistor (or enabling of the internal one) is generally required to guarantee a high level on the line.



The multi-drive feature is controlled by the Multi-driver Enable register (PIO_MDER) and the Multi-driver Disable register (PIO_MDDR). The multi-drive can be selected whether the I/O line is controlled by the PIO Controller or assigned to a peripheral function. The Multi-driver Status register (PIO_MDSR) indicates the pins that are configured to support external drivers.

After reset, the multi-drive feature is disabled on all pins, i.e., PIO_MDSR resets at value 0x0.

42.5.7. Output Line Timings

The following figure shows how the outputs are driven either by writing PIO_SODR or PIO_CODR, or by directly writing PIO_ODSR. This last case is valid only if the corresponding bit in PIO_OWSR is set. The Output Line Timings figure also shows when the feedback in the Pin Data Status register (PIO_PDSR) is available.

Figure 42.3. Output Line Timings

© 2026 Microchip Technology Inc. and its subsidiaries

42.5.8. Inputs

The level on each I/O line can be read through PIO_PDSR. This register indicates the level of the I/O lines regardless of their configuration, whether uniquely as an input, or driven by the PIO Controller, or driven by a peripheral.

Reading the I/O line levels requires the clock of the PIO Controller to be enabled, otherwise PIO_PDSR reads the levels present on the I/O line at the time the clock was disabled.

42.5.9. Input Glitch and Debouncing Filters

Optional input glitch and debouncing filters are independently programmable on each I/O line.

The glitch filter can filter a glitch with a duration of less than 1/2 peripheral clock and the debouncing filter can filter a pulse of less than 1/2 period of a programmable divided slow clock.

The selection between glitch filtering or debounce filtering is done by writing in the PIO Input Filter Slow Clock Disable register (PIO_IFSCDR) and the PIO Input Filter Slow Clock Enable register (PIO_IFSCER). Writing PIO_IFSCDR and PIO_IFSCER, respectively, sets and clears bits in the Input Filter Slow Clock Status register (PIO_IFSCSR).

The current selection status can be checked by reading the PIO_IFSCSR.

- If PIO_IFSCSR[i] = 0: The glitch filter can filter a glitch with a duration of less than 1/2 main system bus clock period.
- If PIO_IFSCSR[i] = 1: The debouncing filter can filter a pulse with a duration of less than 1/2 programmable divided slow clock period.

For the debouncing filter, the period of the divided slow clock is defined by writing in the DIV field of the Slow Clock Divider Debouncing register (PIO_SCDR):

$t_{div_slck} = ((DIV + 1) \times 2) \times t_{slck}$

When the glitch or debouncing filter is enabled, a glitch or pulse with a duration of less than 1/2 selected clock cycle (selected clock represents peripheral clock or divided slow clock depending on PIO_IFSCDR and PIO_IFSCER programming) is automatically rejected, while a pulse with a duration of one selected clock (peripheral clock or divided slow clock) cycle or more is accepted. For pulse durations between 1/2 selected clock cycle and one selected clock cycle, the pulse may or may not be taken into account, depending on the precise timing of its occurrence. Thus for a pulse to be visible, it must exceed one selected clock cycle, whereas for a glitch to be reliably filtered out, its duration must not exceed 1/2 selected clock cycle.

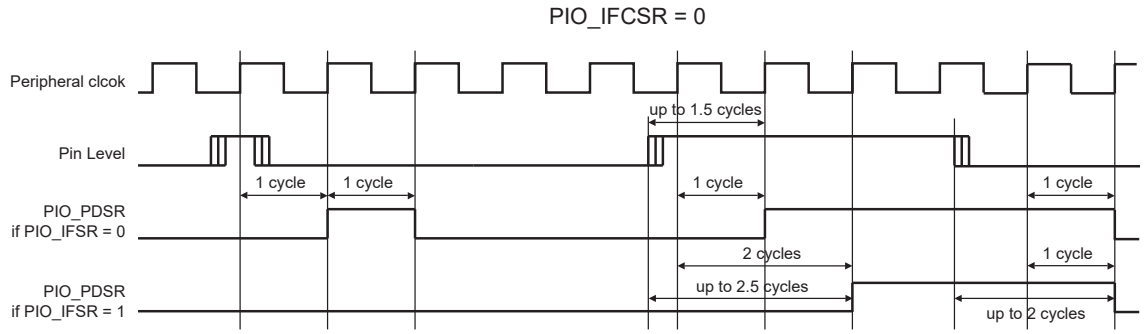
The filters also introduce some latencies, illustrated in the following two figures.

The glitch filters are controlled by the Input Filter Enable register (PIO_IFER), the Input Filter Disable register (PIO_IFDR) and the Input Filter Status register (PIO_IFSR). Writing PIO_IFER and PIO_IFDR respectively sets and clears bits in PIO_IFSR. This last register enables the glitch filter on the I/O lines.

When the glitch and/or debouncing filter is enabled, it does not modify the behavior of the inputs on the peripherals. It acts only on the value read in PIO_PDSR and on the input change interrupt detection. The glitch and debouncing filters require that the peripheral clock is enabled.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 42.4. Input Glitch Filter Timing



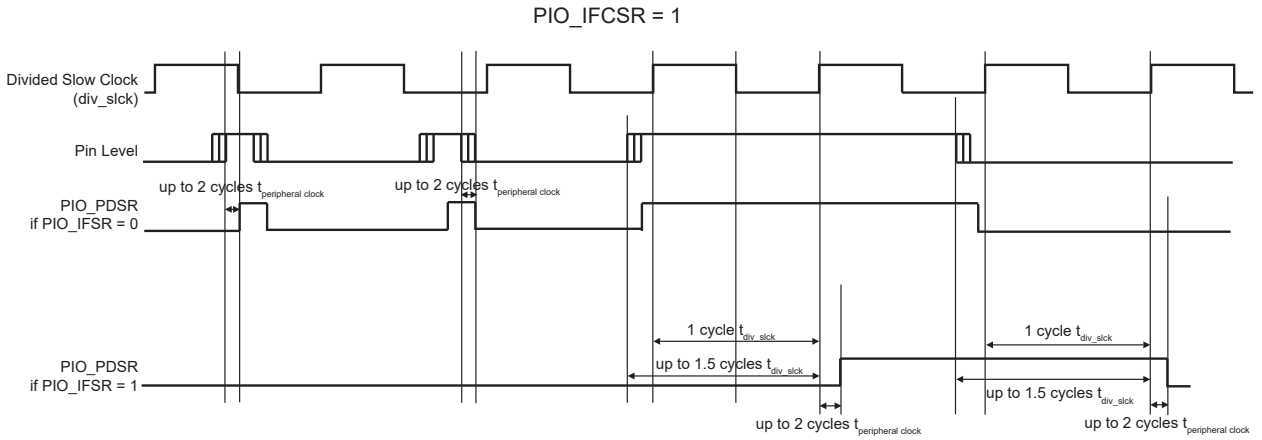


Figure 42.5. Input Debouncing Filter Timing

42.5.10. Input Edge/Level Interrupt

The PIO Controller can be programmed to generate an interrupt when it detects an edge or a level on an I/O line. The Input Edge/Level interrupt is controlled by writing the Interrupt Enable register (PIO_IER) and the Interrupt Disable register (PIO_IDR), which enable and disable the input change interrupt respectively by setting and clearing the corresponding bit in the Interrupt Mask register (PIO_IMR). As input change detection is possible only by comparing two successive samplings of the input of the I/O line, the peripheral clock must be enabled. The Input Change interrupt is available regardless of the configuration of the I/O line, i.e., configured as an input only, controlled by the PIO Controller or assigned to a peripheral function.

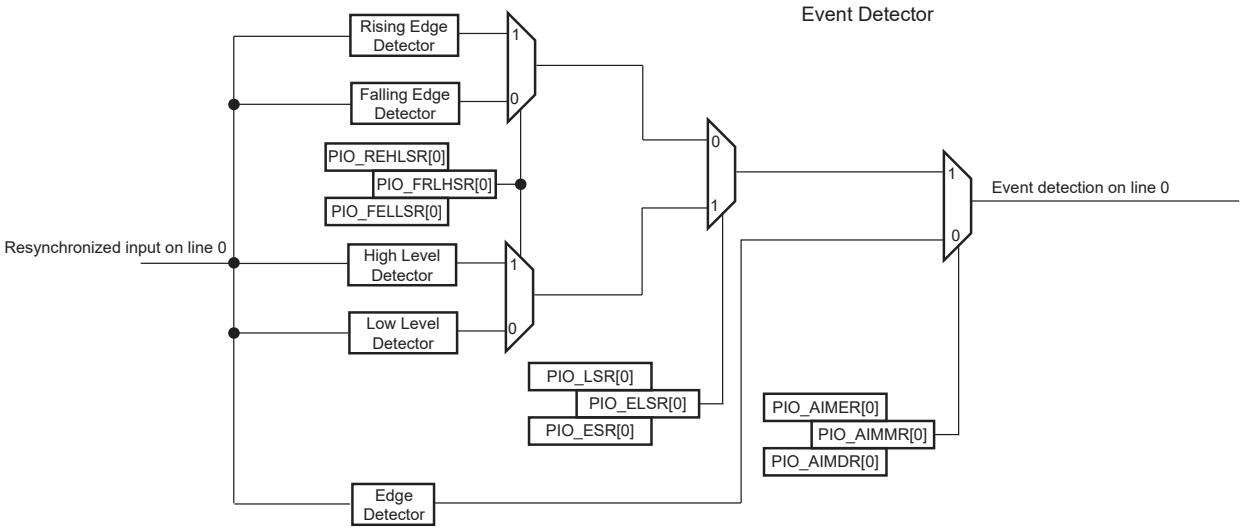
By default, the interrupt can be generated at any time an edge is detected on the input.

Some additional interrupt modes can be enabled/disabled by writing in the Additional Interrupt Modes Enable register (PIO_AIMER) and Additional Interrupt Modes Disable register (PIO_AIMDR). The current state of this selection can be read through the Additional Interrupt Modes Mask register (PIO_AIMMR).

These additional modes are:

- Rising edge detection
- Falling edge detection
- Low-level detection
- High-level detection

In order to select an additional interrupt mode:



© 2026 Microchip Technology Inc. and its subsidiaries

- The type of event detection (edge or level) must be selected by writing in the Edge Select register (PIO_ESR) and Level Select register (PIO_LSR) which select, respectively, the edge and level detection. The current status of this selection is accessible through the Edge/Level Status register (PIO_ELSR).
- The polarity of the event detection (rising/falling edge or high/low-level) must be selected by writing in the Falling Edge/Low-Level Select register (PIO_FELLSR) and Rising Edge/High-Level Select register (PIO_REHLSR) which allow to select falling or rising edge (if edge is selected in PIO_ELSR) edge or high- or low-level detection (if level is selected in PIO_ELSR). The current status of this selection is accessible through the Fall/Rise - Low/High Status register (PIO_FRLHSR).

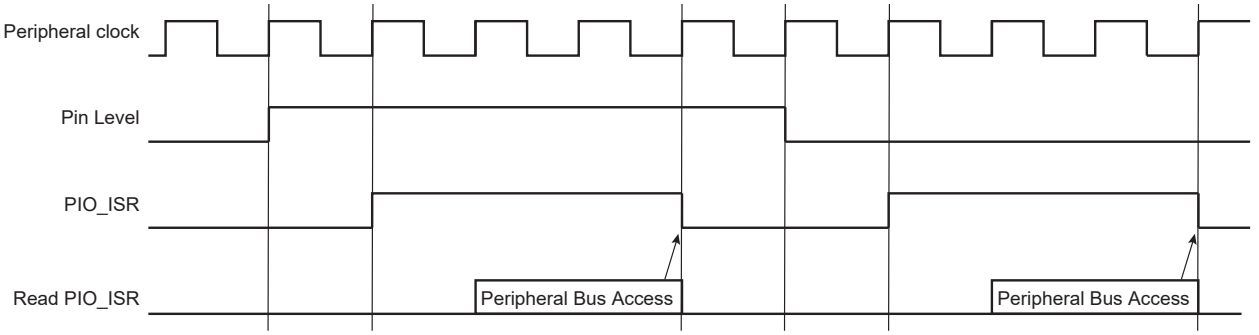
When an input edge or level is detected on an I/O line, the corresponding bit in the Interrupt Status register (PIO_ISR) is set. If the corresponding bit in PIO_IMR is set, the PIO Controller interrupt line is asserted. The interrupt signals of the 32 channels are ORed-wired together to generate a single interrupt signal to the interrupt controller.

When the software reads PIO_ISR, all the interrupts are automatically cleared. This signifies that all the interrupts that are pending when PIO_ISR is read must be handled. When an Interrupt is enabled on a “level”, the interrupt is generated as long as the interrupt source is not cleared, even if some read accesses in PIO_ISR are performed.

Figure 42.6. Event Detector on Input Lines (Figure Represents Line 0)

Example of interrupt generation on following lines:

- Rising edge on PIO line 0
- Falling edge on PIO line 1
- Rising edge on PIO line 2
- Low-level on PIO line 3
- High-level on PIO line 4
- High-level on PIO line 5
- Falling edge on PIO line 6
- Rising edge on PIO line 7
- Any edge on the other lines



The following table provides the required configuration for this example.

© 2026 Microchip Technology Inc. and its subsidiaries

Table 42.1. Configuration for Example Interrupt Generation

Configuration	Description
Interrupt Mode	All the interrupt sources are enabled by writing 32'hFFFF_FFFF in PIO_IER. Then the additional Interrupt mode is enabled for lines 0 to 7 by writing 32'h0000_00FF in PIO_AIMER.
Edge or Level Detection	Lines 3, 4 and 5 are configured in level detection by writing 32'h0000_0038 in PIO_LSR. The other lines are configured in edge detection by default, if they have not been previously configured. Otherwise, lines 0, 1, 2, 6 and 7 must be configured in edge detection by writing 32'h0000_00C7 in PIO_ESR.
Falling/Rising Edge or Low/High-Level Detection	Lines 0, 2, 4, 5 and 7 are configured in rising edge or high-level detection by writing 32'h0000_00B5 in PIO_REHLSR. The other lines are configured in falling edge or low-level detection by default if they have not been previously configured. Otherwise, lines 1, 3 and 6 must be configured in falling edge/low-level detection by writing 32'h0000_004A in PIO_FELLSR.

Figure 42.7. Input Change Interrupt Timings When No Additional Interrupt Modes

42.5.11. Programmable Schmitt Trigger

It is possible to configure each input for the Schmitt trigger. By default the Schmitt trigger is active. Disabling the Schmitt trigger is requested when using the QTouch® Library.

42.5.12. I/O Lines Programming Example

The programming example shown in the following table is used to obtain the following configuration:

- 4-bit output port on I/O lines 0 to 3 (should be written in a single write operation), open-drain, with pull-up resistor
- Four output signals on I/O lines 4 to 7 (to drive LEDs for example), driven high and low, no pull-up resistor, no pull-down resistor
- Four input signals on I/O lines 8 to 11 (to read push-button states for example), with pull-up resistors, glitch filters and input change interrupts
- Four input signals on I/O line 12 to 15 to read an external device status (polled, thus no input change interrupt), no pull-up resistor, no glitch filter
- I/O lines 16 to 19 assigned to peripheral A functions with pull-up resistor
- I/O lines 20 to 23 assigned to peripheral B functions with pull-down resistor
- I/O lines 24 to 27 assigned to peripheral C with input change interrupt, no pull-up resistor and no pull-down resistor
- I/O lines 28 to 31 assigned to peripheral D, no pull-up resistor and no pull-down resistor

Table 42.2. Programming Example

Register	Value to be Written
PIO_PER	0x0000_FFFF

© 2026 Microchip Technology Inc. and its subsidiaries

Table 42.2. Programming Example (continued)

Register	Value to be Written
PIO_PDR	0xFFFF_0000
PIO_OER	0x0000_00FF
PIO_ODR	0xFFFF_FF00
PIO_IFER	0x0000_0F00
PIO_IFDR	0xFFFF_F0FF
PIO_SODR	0x0000_0000
PIO_CODR	0x0FFF_FFFF
PIO_IER	0x0F00_0F00
PIO_IDR	0xF0FF_F0FF
PIO_MDER	0x0000_000F
PIO_MDDR	0xFFFF_FFF0
PIO_PUDR	0xFFF0_00F0
PIO_PUER	0x000F_FF0F
PIO_PPDDR	0xFF0F_FFFF
PIO_PPDER	0x00F0_0000
PIO_ABCDSR0	0xF0F0_0000
PIO_ABCDSR1	0xFF00_0000
PIO_OWER	0x0000_000F
PIO_OWDR	0x0FFF_FFF0

42.5.13. Register Write Protection

To prevent any single software error from corrupting PIO behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the PIO Write Protection Mode Register (PIO_WPMR).

If a write access to a write-protected register is detected, the WPVS flag in the PIO Write Protection Status Register (PIO_WPSR) is set and the field WPVSRC indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading PIO_WPSR.

The following registers can be write-protected:

- PIO Enable Register
- PIO Disable Register
- PIO Output Enable Register
- PIO Output Disable Register
- PIO Input Filter Enable Register
- PIO Input Filter Disable Register
- PIO Multi-driver Enable Register
- PIO Multi-driver Disable Register
- PIO Pull-Up Disable Register
- PIO Pull-Up Enable Register
- PIO Peripheral ABCD Select Register 1
- PIO Peripheral ABCD Select Register 2
- PIO Output Write Enable Register
- PIO Output Write Disable Register

42.6. Register Summary

Each I/O line controlled by the PIO Controller is associated with a bit in each of the PIO Controller User Interface registers. Each register is 32 bits wide. If a parallel I/O line is not defined, writing to the corresponding bits has no effect. Undefined bits read zero. If the I/O line is not multiplexed with any peripheral, the I/O line is controlled by the PIO Controller and PIO_PSR returns one systematically.

Offset	Name	Bit Pos.	7	6	5	4	3	2	1	0
0x00	PIO_PER	31:24	P31	P30	P29	P28	P27	P26	P25	P24

Analog Subsystem

43. Overview

43.1. Block Diagram

Refer to Analog-to-Digital Controller (ADC).

43.2. Components

- Analog-to-Digital Controller

43.3. Product Dependencies

43.3.1. Clocks

The ADC clocks are controlled by the PMC, which is a part of the system controller.

43.3.2. Interrupts

Refer to Peripheral Identifiers.

43.3.3. Reset

The ADC resets to the processor and to the peripherals reset line.

43.3.4. I/Os

The eight analog I/Os (AD[7:0]) share the dedicated power and ground rails VDDANA and GNDANA. To avoid any unwanted input loading, disable the pull-up and pull-down resistors before using these lines in the PIO_PUDR and PIO_PDDR registers.

43.3.5. Special Functions in SFR

None.

© 2026 Microchip Technology Inc. and its subsidiaries

44. Analog-to-Digital Controller (ADC)

44.1. Description

The ADC is based on a 12-bit Analog-to-Digital Converter (ADC) managed by an ADC Controller providing enhanced resolution up to 16 bits. See the Block Diagram. It also integrates a 8-to-1 analog multiplexer, making possible the analog-to-digital conversions of 8 analog lines. The conversions extend from the voltage on pin ADVREFN to the voltage carried on pin ADVREFP.

Conversion results are reported in a common register for all channels, as well as in a channel-dedicated register.

The 13-bit, 14-bit, 15-bit and 16-bit resolution modes are obtained by averaging multiple samples to decrease quantization noise. For the 13-bit mode, 4 samples are used, which gives a real sample rate of 1/4 of the actual sample frequency. For the 14-bit mode, 16 samples are used, giving a real sample rate of 1/16 of the actual sample frequency. For the 15-bit and 16-bit modes, respectively 64 and 256 samples are used, giving a real sample rate of respectively 1/64 and 1/256 of the actual sample frequency. This arrangement allows conversion speed to be traded off against for better accuracy.

The software trigger, external trigger on rising edge of the ADTRG pin or internal triggers from Timer Counter output(s) are configurable.

The comparison circuitry allows automatic detection of values below a threshold, higher than a threshold, in a given range or outside the range, thresholds and ranges being fully configurable.

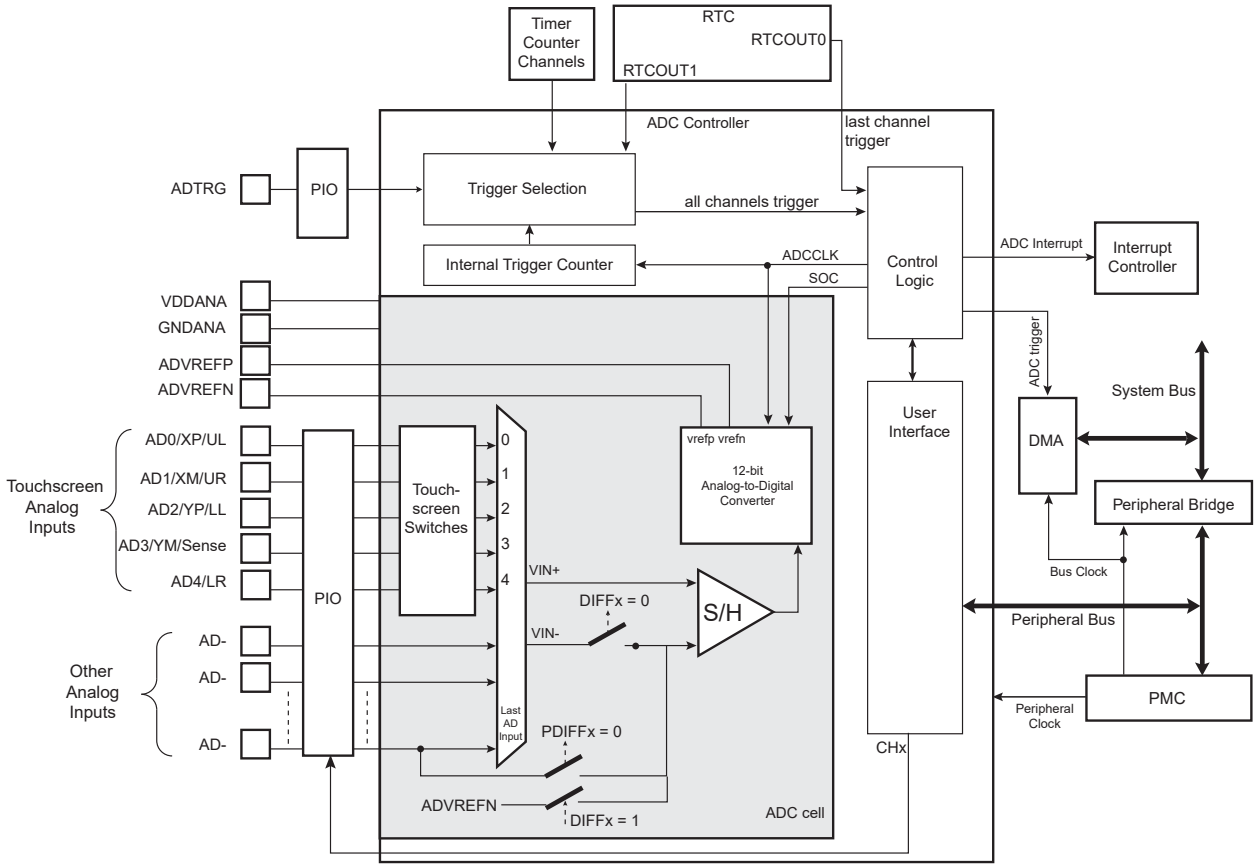
The ADC Controller internal fault output is directly connected to the PWM fault input. This input can be asserted by means of comparison circuitry to immediately put the PWM output in a safe state (pure combinational path).

The ADC also integrates a Sleep mode and a conversion sequencer and connects with a DMA channel. These features reduce both power consumption and processor intervention.

This ADC has a selectable single-ended, pseudo-differential or fully differential input.

This ADC Controller includes a Resistive Touchscreen Controller. It supports 4-wire and 5-wire technologies.

44.2. Embedded Characteristics



- 12-bit Resolution with Enhanced Mode up to 16 bits
- 1 MSps Conversion Rate
- Digital Averaging Function providing Enhanced Resolution Mode up to 16 bits
- Wide Range of Power Supply Operation
- Selectable Single-Ended, Pseudo-Differential or Differential Input Voltage
- Digital correction of offset and gain errors
- Resistive 4-wire and 5-wire Touchscreen Controller
  - Position and pressure measurement for 4-wire screens
  - Position measurement for 5-wire screens
  - Average of up to 8 measures for noise filtering
- Programmable Pen Detection Sensitivity
- Integrated Multiplexer Offering Up to 8 Independent Analog Inputs
- Individual Enable and Disable of Each Channel
- Hardware or Software Trigger from:

© 2026 Microchip Technology Inc. and its subsidiaries

  - External trigger pin
  - Timer counter outputs (corresponding TIOA trigger)
  - ADC internal trigger counter
  - Trigger on pen contact detection
  - PWM event line
- Drive of PWM Fault Input
- DMA Support
- Two Sleep Modes (Automatic Wake-Up on Trigger)
  - Lowest power consumption (voltage reference off between conversions)
  - Fast wake-up time response on trigger event (voltage reference on between conversions)
- Channel Sequence Customizing
- Automatic Window Comparison of Converted Values
- Register Write Protection

44.3. Block Diagram

Table 44.1. ADC Pin Description (continued)

Pin Name	Description
GNDANA	Analog ground supply
ADVREFP	Reference voltage
ADVREFN	Reference voltage
AD[7:0]	Analog input channels
ADTRG	External trigger

44.5. Product Dependencies

44.5.1. Power Management

The ADC Controller is not continuously clocked. The programmer must first enable the ADC Controller peripheral clock in the Power Management Controller (PMC) before using the ADC Controller. However, if the application does not require ADC operations, the ADC Controller clock can be stopped when not needed and restarted when necessary. Configuring the ADC Controller does not require the ADC Controller clock to be enabled.

44.5.2. Interrupt Sources

The ADC interrupt line is connected on one of the internal sources of the Interrupt Controller. Using the ADC interrupt requires the interrupt controller to be programmed first.

44.5.3. I/O Lines

The digital inputs ADx and ADTRG are multiplexed with digital functions on the I/O lines.

ADx inputs are selected as inputs of the ADCC when writing a one in the corresponding ADC_CHER.CHx bit and the associated I/O is automatically turned in Analog mode.

44.5.4. Hardware Triggers

The ADC can use internal signals to start conversions. See the ADC_MR.TRGSEL field description in ADC_MR for exact wiring of internal triggers.

44.5.5. Fault Output

The ADC Controller has the FAULT output connected to the FAULT input of PWM. See Fault Event and section “Pulse Width Modulation Controller (PWM)”.

44.6. Functional Description

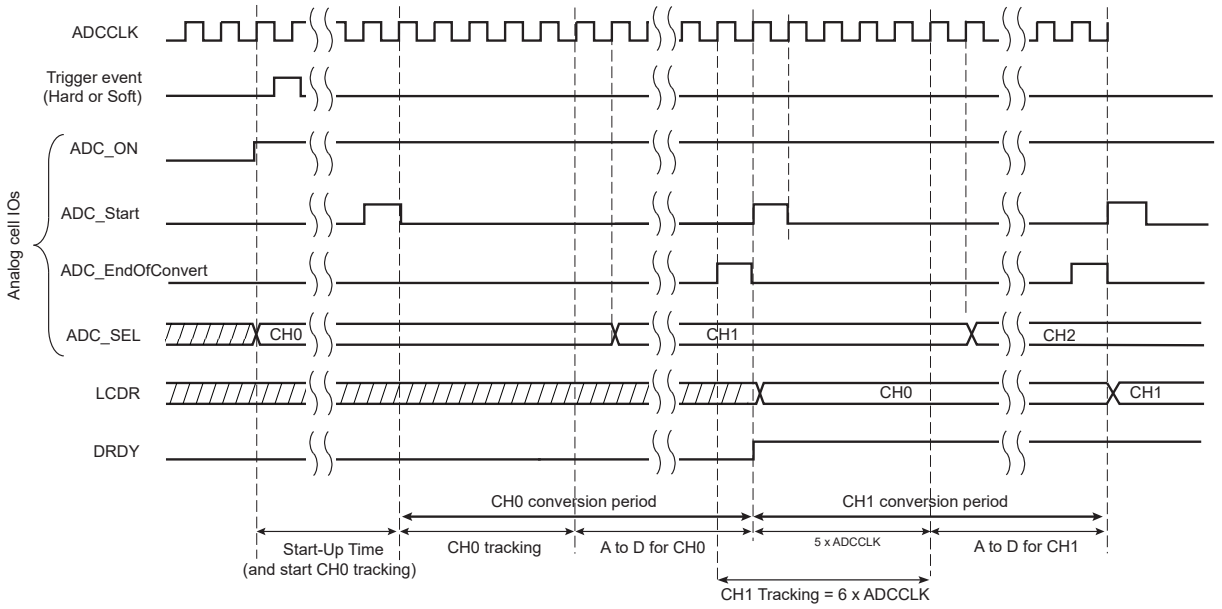
44.6.1. Analog-to-Digital Conversion

Once the programmed start-up time (ADC_MR.STARTUP) has elapsed, ADC conversions are sequenced by three operating times:

- Tracking time—the time for the ADC to charge its input sampling capacitor to the input voltage (depends on the impedance of the analog driver connected to the package pin). When several channels are converted to Continuous mode (i.e., without waiting for a trigger event), the inherent tracking time is 6 ADC clock cycles. However, the tracking time can be increased using the TRACKTIM field in the Mode register (ADC_MR) and the TRACKX4 bit in the Extended Mode register (ADC_EMR).
- ADC inherent conversion time—the time for the ADC to convert the sampled analog voltage. This time is constant and is defined from start of conversion to end of conversion.
- Channel conversion period—the effective time between the end of the current channel conversion and the end of the next channel conversion.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 44.2. Sequence of Consecutive ADC Conversions with TRACKTIM = 0



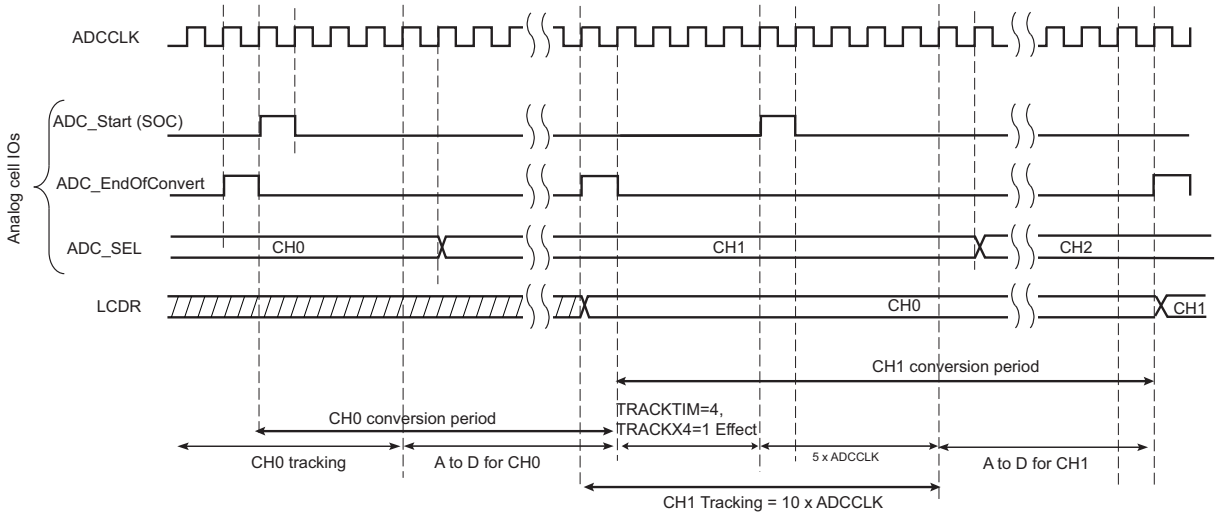


Figure 44.3. Sequence of Consecutive ADC Conversions with TRACKTIM = 4 and TRACKX4 = 1

44.6.2. ADC Clock

The ADC uses the ADC clock (ADCCLK) to perform conversions. The ADC clock frequency is selected in the ADC_MR.PRESCAL.

To generate the ADC clock, the prescaler has two clock sources: the peripheral clock and the GCLK clock. This clock source is selected using the SRCCLK bit in the Extended Mode register (ADC_EMR).

If GCLK is selected as a source clock, the ADC clock frequency is independent of the processor/bus clock. At reset, the peripheral clock is selected.

If ADC_EMR.SRCCLK is cleared, the prescaler clock (presc_clk) is driven by peripheral_clock. If ADC_EMR.SRCCLK is set, the prescaler clock is driven by GCLK. The ADC clock frequency is between fpresc_clk/2, if PRESCAL is 0, and fpresc_clk/512, if PRESCAL is set to 255 (0xFF).

PRESCAL must be programmed to provide the ADC clock frequency parameter provided in the “Electrical Characteristics” section.

© 2026 Microchip Technology Inc. and its subsidiaries

44.6.3. ADC Reference Voltage

The voltage reference input of the ADC is the ADVREFP pin and the negative reference voltage is ADVREFN. Refer to the section “Electrical Characteristics”.

44.6.4. ADC Input Sampling Capacitor Charging Time (Tracking Time)

The ADC embeds an input capacitor to sample the analog input. This capacitor must be fully charged to provide a correct conversion result.

The analog sensor connected to the ADC has a serial impedance (also known as “output impedance” or “source impedance”). The tracking time must ensure the error introduced by the charge is lower than the quantification error introduced by the ADC resolution.

It is recommended to use a value higher or equal to 10 x Rs x C for the tracking time (refer to the Electrical Characteristics section for value of C).

The ADC has an inherent tracking time, and additional time can be configured (see ADC_MR).

The full voltage range of the ADC (i.e., ADVREFP-ADVREFN) must be used to calculate the required tracking time, especially when multiple channels are enabled for conversion. In such case, one channel can be tied to ADVREFN and the consecutive channel in the conversion sequence can be tied to ADVREFP.

44.6.5. Conversion Resolution

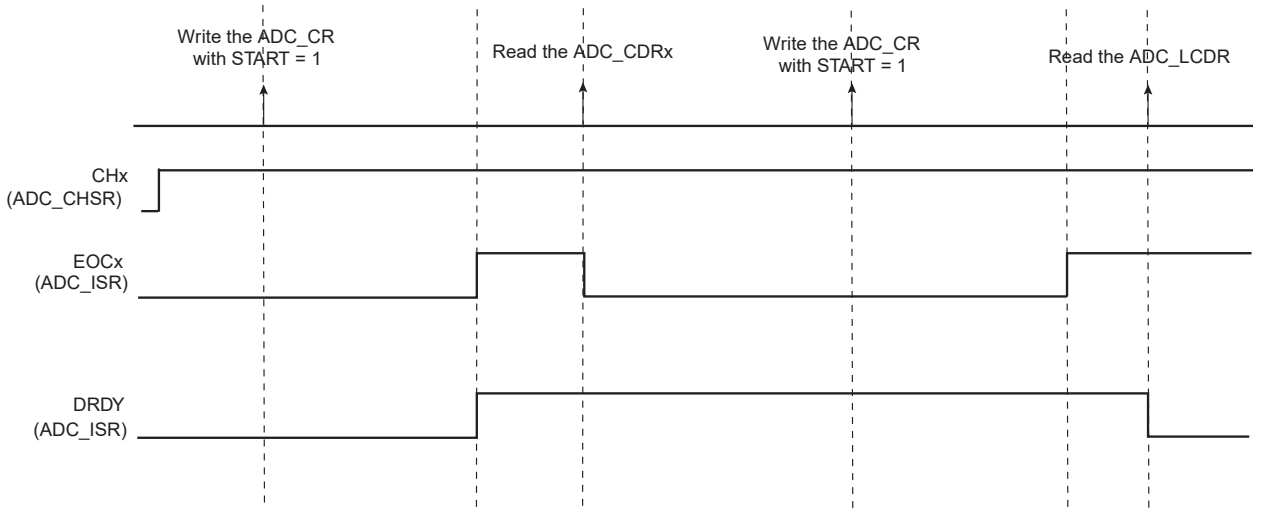
The ADC has a native resolution of 12 bits.

The ADC Controller provides enhanced resolution up to 16 bits by means of digital averaging.

If ADTRG is asynchronous to the ADC peripheral clock, the internal resynchronization introduces a jitter of 1 peripheral clock. This jitter may reduce the resolution of the converted signal.

The same applies when using the independent clock (ADC_MR.SRCCLK = 1), if the provided clock is asynchronous to ADC peripheral clock.

44.6.6. Conversion Results



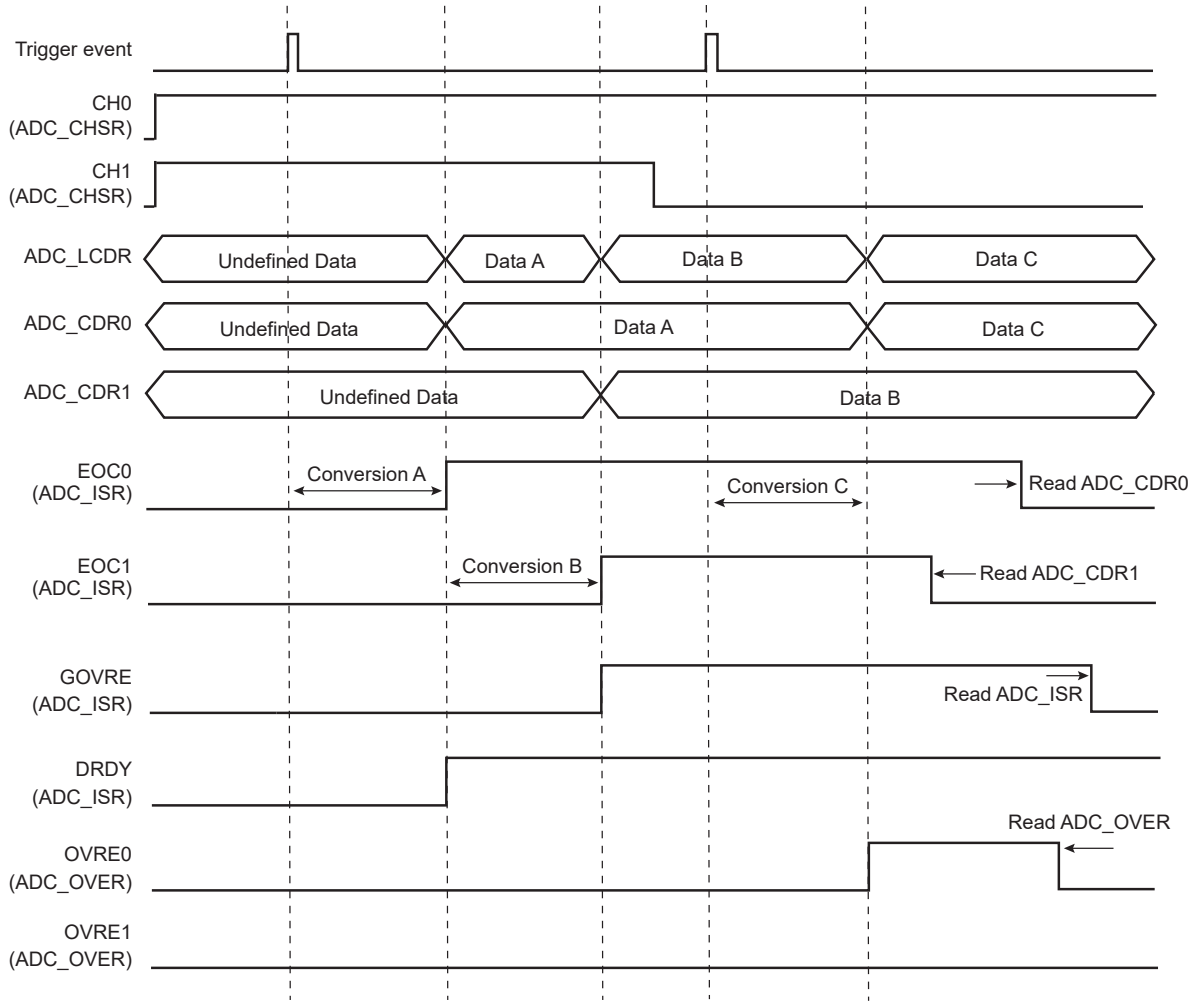
When a conversion is completed, the resulting digital value is stored in the Channel Data register (ADC_CDRx) of the current channel and in the Last Converted Data register (ADC_LCDR). By setting the TAG option in ADC_EMR, ADC_LCDR presents the channel number associated with the last converted data in the CHNB field.

When a conversion is completed, the channel EOC bit and the DRDY bit in the Interrupt Status register (ADC_ISR) are set. In the case of a connected DMA channel, DRDY rising triggers a data request. In any case, either EOC and DRDY can trigger an interrupt.

Reading one of the ADC_CDRx clears the corresponding EOC bit. Reading ADC_LCDR clears the DRDY bit.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 44.4. EOCx and DRDY Flag Behavior



If ADC_CDR is not read before further incoming data is converted, the corresponding OVREx flag is set in the Overrun Status register (ADC_OVER).

If new data is converted when DRDY is high, ADC_ISR.GOVRE is set.

The OVREx flag is automatically cleared when ADC_OVER is read, and the GOVRE flag is automatically cleared when ADC_ISR is read.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 44.5. EOCx, OVREx and GOVREx Flag Behavior

WARNING If the corresponding channel is disabled during a conversion or if it is disabled and then reenabled during a conversion, its associated data and corresponding EOCx and GOVRE flags in ADC_ISR and OVREx flags in ADC_OVER are unpredictable.

44.6.7. Maximum Sampling Frequency

The maximum sampling frequency of 1 MSps can be reached when the following conditions are met:

- Only one channel is enabled. Ex.: ADC_CHSR=1, 2, 4, 8, 16.
- Continuous mode is selected (ADC_TRGR.TRGMOD=6).
- The impedance of the analog source driving the ADC input allows ADC_MR.TRACKTIM=0.
- The ADCCLK clock frequency is configured to 1 MSps x 20 via the prescaler (ADC_MR.PRESCAL) of the source clock (the peripheral clock is driven by a generic clock, GCK). The minimum prescaler is 2.

Note: For sampling frequencies higher than 500 ksps, ADC_ACR.IBCTL must be written to 1.

© 2026 Microchip Technology Inc. and its subsidiaries

44.6.8. Conversion Results Format

The conversion results can be signed (2's complement) or unsigned depending on the value of the ADC_EMR.SIGNMODE field.

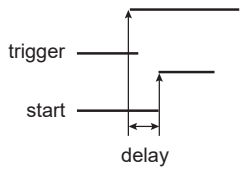
If conversion results are signed and resolution is less than 16 bits, the sign is extended up to the bit 15 (for example, 0xF43 for 12-bit resolution is read as 0xFF43, and 0x467 is read as 0x0467).

44.6.9. Conversion Triggers

Conversions of the active analog channels are started with a software or hardware trigger. The software trigger is provided by writing the Control register (ADC_CR) with the START bit at 1 and ADC_TRGR.TRGMOD=0.

The list of external/internal events is provided in ADC_MR. The hardware trigger is selected using the ADC_MR.TRGSEL field. The selected hardware trigger is enabled if TRGMOD = 1, 2 or 3 in the Trigger register (ADC_TRGR). In these modes, the software trigger is disabled (writing ADC_CR.START=1 has no effect).

The ADC also provides a Dual Trigger mode (ADC_LCTMR.DUALTRIG = 1) in which the higher index channel can be sampled at a rhythm different from the other channels. The trigger of the last channel is generated by the RTC. See Last Channel Specific Measurement Trigger.



The ADC_TRGR.TRGMOD field selects the hardware trigger from the following:

- Any edge, either rising or falling or both, detected on the external trigger pin ADTRG or internal triggers
- The Pen Detect, depending on how the PENDET bit is set in the Touchscreen Mode register (ADC_TSMR)
- A continuous trigger, meaning the ADC Controller restarts the next sequence as soon as it finishes the current one
- A periodic trigger, which is defined by programming the ADC_TRGR.TRGPER field

The minimum time between two consecutive trigger events must be strictly greater than the duration time of the longest conversion sequence according to configuration of registers ADC_MR, ADC_CHSR, ADC_SEQR1, and ADC_TSMR.

If a hardware trigger is selected, the start of a conversion is triggered after a delay starting at each rising edge of the selected signal. Due to asynchronous handling, the delay may vary in a range of two peripheral clock periods to one ADC clock period. This delay introduces sampling jitter in the A/D conversion process and may therefore degrade the conversion performance (e.g., SNR, THD).

Figure 44.6. Hardware Trigger Delay

If one of the TIOA outputs is selected, the corresponding Timer Counter channel must be programmed in Waveform mode.

Only one start command is necessary to initiate a conversion sequence on all the enabled channels. The ADC hardware logic automatically performs the conversions on the active channels, then waits for a new request. The Channel Enable (ADC_CHER) and Channel Disable (ADC_CHDR) registers enable the analog channels to be enabled or disabled independently.

If the ADC is used with a DMA, only the transfers of converted data from enabled channels are performed and the resulting data buffers should be interpreted accordingly.

© 2026 Microchip Technology Inc. and its subsidiaries

44.6.10. Sleep Mode and Conversion Sequencer

The ADC Sleep mode maximizes power saving by automatically deactivating the ADC when it is not being used for conversions. Sleep mode is selected by setting ADC_MR.SLEEP.

Sleep mode is managed by a conversion sequencer, which automatically processes the conversions of all channels at lowest power consumption.

This mode can be used when the minimum period of time between two successive trigger events is greater than the start-up period of the ADC. Refer to the section “Electrical Characteristics”.

When a start conversion request occurs, the ADC is automatically activated. As the analog cell requires a start-up time, the logic waits during this time and starts the conversion on the enabled channels. When all conversions are complete, the ADC is deactivated until the next trigger. Events triggered during the sequence are ignored.

The conversion sequencer allows automatic processing with minimum processor intervention and optimized power consumption. Conversion sequences can be performed periodically using the internal timer (ADC_TRGR) or the PWM event line. The periodic acquisition of several samples can be processed automatically without any intervention of the processor via the DMA.

The sequence can be customized by programming the Sequence Channel registers ADC_SEQR1 and setting the USEQ bit of the Mode register (ADC_MR). The user can choose a specific order of channels and can program up to 8 conversions by sequence. The user is free to create a personal sequence by writing channel numbers in ADC_SEQR1. Not only can channel numbers be written in any sequence, channel numbers can be repeated several times. When ADC_MR.USEQ is set, ADC_SEQR1.USCHx are used to define the sequence. Only enabled USCHx fields will be part of the sequence. Each USCHx field has a corresponding enable, CHx-1, in ADC_CHER.

If all ADC channels (i.e., 8) are used on an application board, there is no restriction of usage of the user sequence. However, if some ADC channels are not enabled for conversion but rather used as pure digital inputs, the respective indexes of these channels cannot be used in the user sequence fields (see ADC_SEQR1). For example, if channel 4 is disabled (ADC_CHSR[4] = 0), ADC_SEQR1 fields USCH1 up to USCH8 must not contain the value 4. Thus the length of the user sequence may be limited by this behavior.

As an example, if only four channels over 8 (CH0 up to CH3) are selected for ADC conversions, the user sequence length cannot exceed four channels. Each trigger event may launch up to four successive conversions of any combination of channels 0 up to 3 but no more (i.e., in this case the sequence CH0, CH0, CH1, CH1, CH1 is impossible).

A sequence that repeats the same channel several times requires more enabled channels than channels actually used for conversion. For example, the sequence CH0, CH0, CH1, CH1 requires four enabled channels (four free channels on application boards) whereas only CH0, CH1 are really converted.

Note: The reference voltage pins always remain connected in Normal mode as in Sleep mode.

44.6.11. Comparison Window

The ADC Controller features automatic comparison functions. It compares converted values to a low threshold, a high threshold or both, depending on the value of the ADC_EMR.CMPMODE field. The comparison can be done on all channels or only on the channel specified in the ADC_EMR.CMPSEL field. To compare all channels, ADC_EMR.CMPALL must be set.

If set, ADC_EMR.CMPTYPE can be used to discard all conversion results that do not match the comparison conditions. Once a conversion result matches the comparison conditions, all the subsequent conversion results are stored in ADC_LCDR (even if these results do not meet the comparison conditions). Setting ADC_CR.CMPRST immediately stops the conversion result storage until the next comparison match.

© 2026 Microchip Technology Inc. and its subsidiaries

If ADC_EMR.CMPTYPE is cleared, all conversions are stored in ADC_LCDR. Only the conversions that match the comparison conditions trigger the ADC_ISR.COMPE flag.

Moreover, a filtering option can be set by writing the number of consecutive comparison matches needed to raise the flag. This number can be written and read in the ADC_EMR.CMPFILTER field. The filtering option is dedicated to reinforcing the detection of an analog signal overpassing a predefined threshold. The filter is cleared as soon as ADC_ISR is read, so this filtering function must be used with peripheral DMA controller and works only when using Interrupt mode (no polling).

The flag can be read on ADC_ISR.COMPE and can trigger an interrupt.

The high threshold and the low threshold can be read/write in the Compare Window register (ADC_CWR).

Depending on the sign of the conversion, chosen with the ADC_EMR.SIGNMODE field, the high threshold and low threshold values must be signed or unsigned to maintain consistency during the comparison. If the conversion is signed, both thresholds must also be signed; if the conversion is unsigned, both thresholds must be unsigned. If comparison occurs on all channels, the ADC_EMR.SIGNMODE field must be set to ALL_UNSIGNED or ALL_SIGNED and the thresholds must be set accordingly.

44.6.12. Pseudo-Differential, Differential and Single-Ended Input Modes

44.6.12.1.Input-Output Transfer Functions

The ADC can be configured to operate in the following input voltage modes:

- Single-Ended—ADC_CCR.DIFFx = 0 and ADC_PDR.PDIFFx = 0. This is the default mode after a reset.
- Differential—ADC_CCR.DIFFx = 1 and ADC_PDR.PDIFFx = 0 (see the figure below). In Differential mode, the ADC requires differential input signals having a VDD/2 common mode voltage (refer to the section “Electrical Characteristics”).
- • Pseudo-Differential—ADC_PDR.PDIFFx = 1. In Pseudo-Differential mode, one of the analog pins is used as the negative input of the ADC (see table Input Pins and Channel Numbers in Pseudo-Differential Mode). The ADC samples the other analog inputs with respect to this one. The common mode input range is 0 to VDD (refer to the section “Electrical Characteristics”).

The following equations provide the unsigned ADC input-output transfer function in each mode(1). With signed conversions (see field ADC_EMR.SIGNMODE), subtract 2047 from the ADC_LCDR.DATA value given below. Note that the Single-Ended mode introduces a x2 gain compared to the Pseudo-Differential mode.

In the formula, REFP = VREFP, REFN = VREFN.

Single-Ended mode:

$$\text{ADC_LCDR.LDATA} = \frac{\text{ADx} - \text{REFN}}{\text{REFP} - \text{REFN}} \times 2^{12}$$

Differential mode:

$$\text{ADC_LCDR.LDATA} = \left(1 + \frac{\text{ADx} - \text{ADx+1}}{\text{REFP} - \text{REFN}}\right) \times 2^{11}$$

Pseudo-Differential mode:

$$\text{ADC_LCDR.LDATA} = \left(1 + \frac{\text{ADx} - \text{AD7}}{\text{REFP} - \text{REFN}}\right) \times 2^{11}$$

Note: Equations assume ADC_EMR.OSR = 1

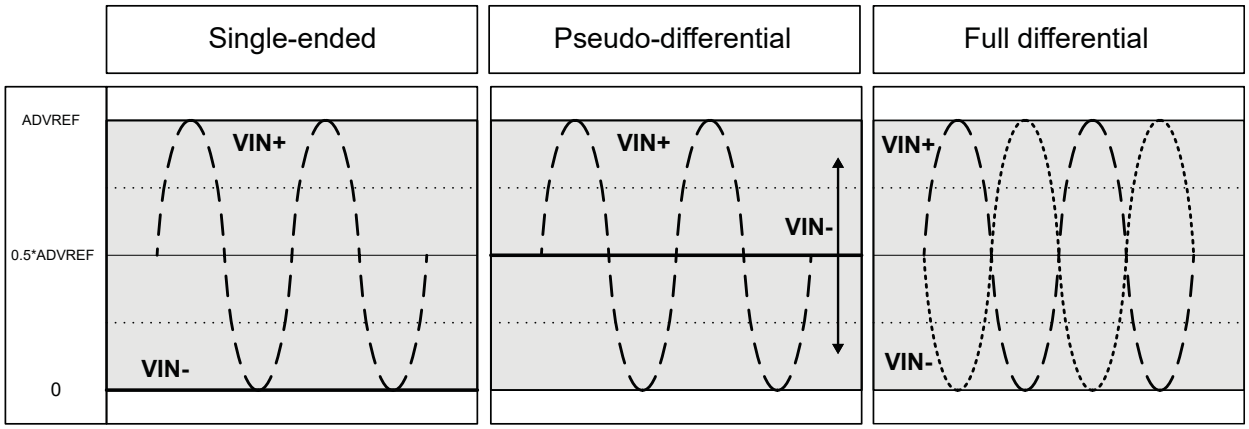
If ADC_MR.ANACH is set, the ADC can manage both differential channels and single-ended channels. If ADC_MR.ANACH is cleared, the parameters defined in ADC_CCR are applied to all channels.

© 2026 Microchip Technology Inc. and its subsidiaries

The following tables provide the internal positive and negative ADC inputs assignment with respect to the programmed mode (ADC_CCR.DIFFx and ADC_PDR.PDIFFx).

For example, if Differential mode is required on channel 0, input pins AD0 and AD1 are used. In this case, only channel 0 must be enabled by writing a 1 to ADC_CHER.CH0.

Table 44.2. Input Pins and Channel Numbers in Single-Ended and Differential Modes



Internal ADC Inputs (VIN+, VIN-)		Channel Number	
Single-Ended Mode	Differential Mode	Single-Ended Mode	Differential Mode
AD0, ADVREFN	AD0, AD1	CH0	CH0
AD1, ADVREFN	–	CH1	
AD2, ADVREFN	AD2, AD3	CH2	CH2
AD3, ADVREFN	–	CH3	
AD4, ADVREFN	AD4, AD5	CH4	CH4
AD5, ADVREFN	–	CH5	
AD6, ADVREFN	AD6, AD7	CH6	CH6
AD7, ADVREFN	–	CH7	

In Pseudo-Differential mode, inputs are managed by a 8/2:1-channel analog multiplexer. See the table below.

Table 44.3. Input Pins and Channel Numbers in Pseudo-Differential Mode

Internal ADC Inputs (VIN+, VIN-)	Channel Number
AD0, AD7	CH0
AD1, AD7	CH1
AD2, AD7	CH2
AD3, AD7	CH3
AD4, AD7	CH4
AD5, AD7	CH5
AD6, AD7	CH6
GNDANA, AD7	CH7

Figure 44.7. Analog Full Scale Ranges in Single-Ended/Pseudo-Differential/Differential Applications

44.6.13. ADC Timings

The ADC start-up time is programmed through the ADC_MR.STARTUP field. Refer to the section “Electrical Characteristics”.

The ADC Controller provides an inherent tracking time of six ADC clock cycles.

© 2026 Microchip Technology Inc. and its subsidiaries

A minimal tracking time is necessary for the ADC to guarantee the best converted final value between two conversions. The tracking time can be adjusted to accommodate a range of source impedances. If more than six ADC clock cycles are required, the tracking time can be increased using the ADC_MR.TRACKTIM field and ADC_EMR.TRACKX4.

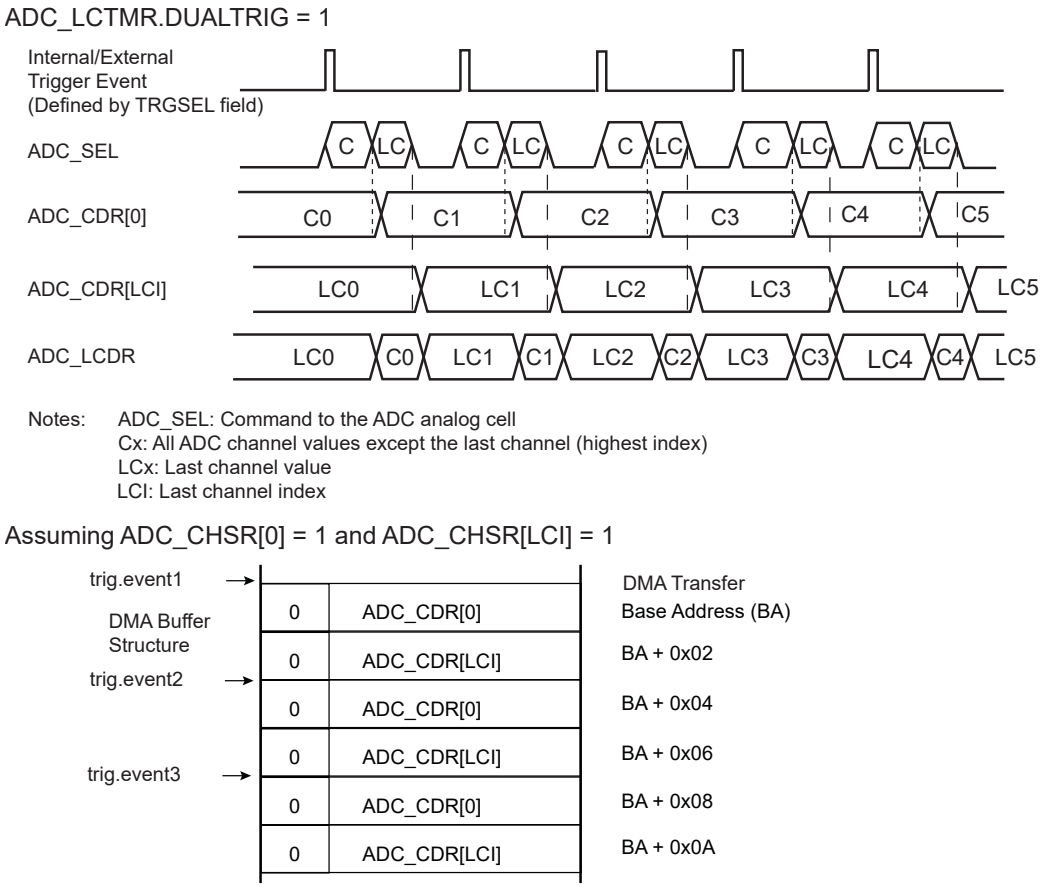
WARNING No input buffer amplifier to isolate the source is included in the ADC. Refer to the section "Electrical Characteristics".

44.6.14. Last Channel Specific Measurement Trigger

The last channel (higher index available) embeds a specific mode allowing a measurement trigger period which differs from other active channels. This allows efficient management of the conversions especially if the channel is driven by a device with a variation of a different frequency from other converted channels (for example, but not limited to, temperature sensor).

The last channel can be sampled in different ways through the ADC Controller. The different methods of sampling depend on the ADC_TRGR.TRGMOD configuration field and on ADC_CHSR.CH7.

The last channel conversion can be triggered like the other channels by enabling ADC_CHER.CH7.



The manual start can only be performed if field TRGMOD = 0. When ADC_CR.START is set, the last channel conversion is scheduled together with the other enabled channels (if any). The result of the conversion is placed in the ADC_CDR7 register, and the associated ADC_ISR.EOC7 flag is set.

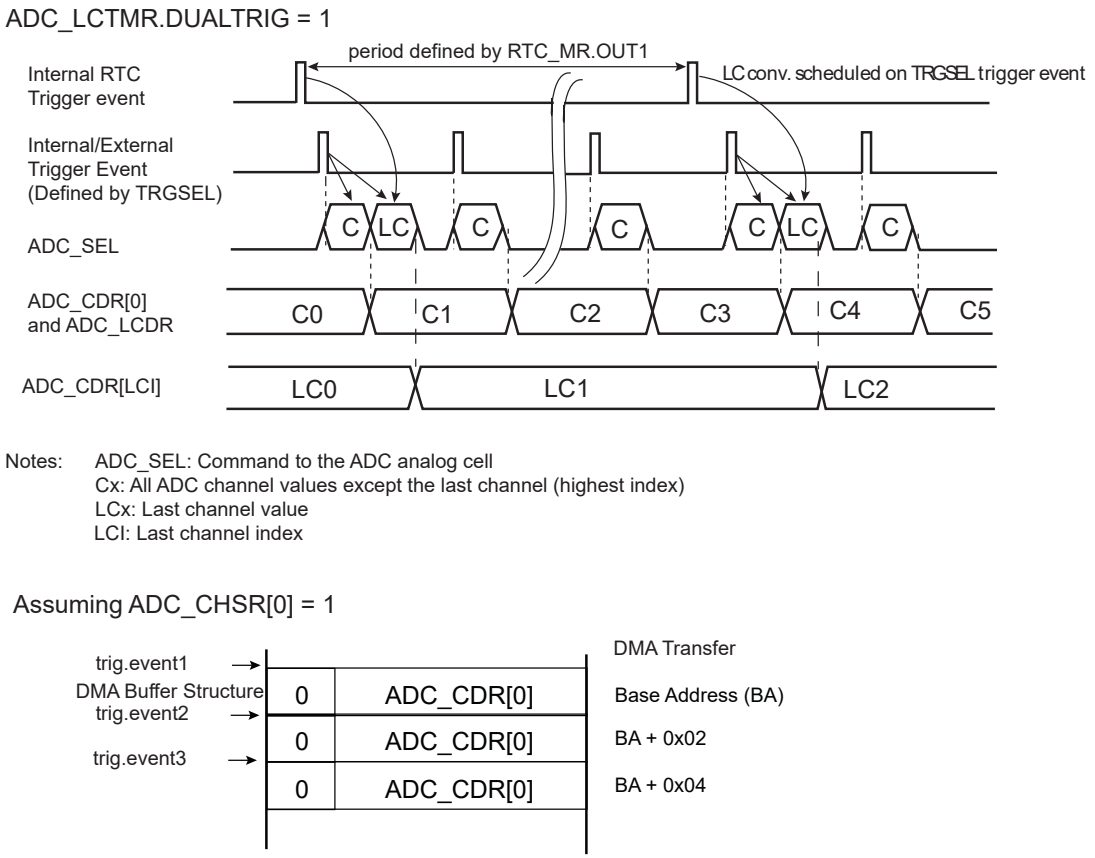
If the last channel is enabled in the Channel Status register (ADC_CHSR), ADC_LCTMR.DUALTRIG is cleared and field TRGMOD = 1, 2, 3, 5, the last channel is periodically converted together with the other enabled channels and the result is placed in the ADC_LCDR and ADC_CDR7 registers. Thus the last channel conversion result is part of the DMA Controller buffer (see the following figure).

When the conversion result matches the conditions defined in ADC_LCTMR and ADC_LCCWR, the ADC_ISR.LCCHG flag is set.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 44.8. Same Trigger for All Channels (ADC_CHSR[LCI] = 1 and ADC_TRGR.TRGMOD = 1, 2, 3, 5)

If the last channel is driven by a device with a slower variation compared to other channels (temperature sensor for example), the channel can be enabled/disabled at any time. However, this may not be optimal for downstream processing.



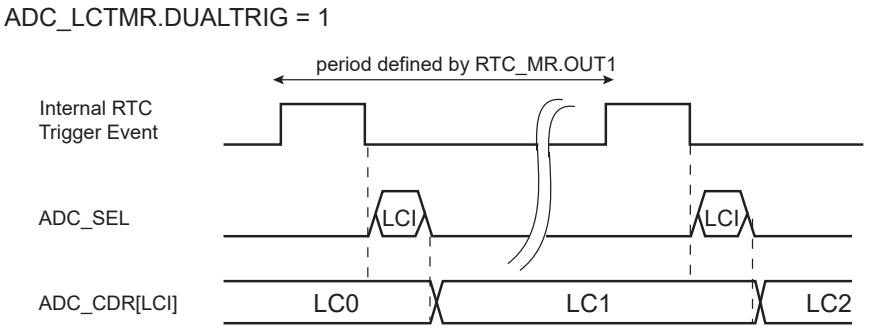
The ADC Controller allows a different way of triggering the measurement when DUALTRIG is set in the Last Channel Trigger Mode register (ADC_LCTMR) but CH7 is not set in ADC_CHSR.

Under these conditions, the last channel conversion is triggered with a period defined by the field RTC_MR.OUTx (see Block Diagram for the value of 'x') while other channels are still active and triggered by internal/external triggers. The RTC event is processed on the next internal/external trigger event, as shown in the following figure. The internal/external trigger for other channels is selected through the ADC_MR.TRGSEL field.

When DUALTRIG = 1, the result of each conversion of channel 7 is only uploaded in the ADC_CDR7 register and not in ADC_LCDR (see the following figure). Therefore, there is no change in the structure of the peripheral DMA controller buffer due to the conversion of the last channel: only the enabled channels are kept in the buffer. The end of conversion of the last channel is reported by the ADC_ISR.EOC7 flag.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 44.9. Independent Trigger Measurement for Last Channel (ADC_CHSR[LCI] = 0 and ADC_TRGR.TRGMOD = 1, 2, 3, 5)



If DUALTRIG = 1 and field ADC_TRGR.TRGMOD = 0 and none of the channels are enabled in ADC_CHSR (ADC_CHSR = 0), then only channel 7 is converted at a rate defined by the trigger event signal that can be configured in RTC_MR.OUT1 (see the following figure).

This mode of operation, when combined with the Sleep mode operation of the ADC Controller, provides a low-power mode for last channel measure. This assumes there is no other ADC conversion to schedule at a high sampling rate or no other channel to convert.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 44.10. Only Last Channel Measurement Triggered at Low Speed (ADC_CHSR[LCI] = 0 and ADC_TRGR.TRGMOD = 0)

Notes: ADC_SEL: Command to the ADC analog cell
LCx: Last channel value
LCI: Last channel index

44.6.15. Enhanced Resolution Mode and Digital Averaging Function

44.6.15.1.Enhanced Resolution Mode

The Enhanced Resolution mode is enabled if the OSR field is configured to 1, 2, 3 or 4 in ADC_EMR. The enhancement is based on a digital averaging function.

There is no averaging on the last index channel if the measure is triggered by an RTC event.

In this mode, the ADC Controller will trade off conversion speed against accuracy by averaging multiple samples, thus providing a digital low-pass filter function.

The selected oversampling ratio applies to all enabled channels when triggered by an RTC event.

$$\text{ADC_LCDR.LDATA} = \frac{1}{M} \times \sum_{k=0}^{k=N-1} \text{ADC}(k)$$

where N and M are as shown in the table below.

Table 44.4. Digital Averaging Function Configuration versus OSR Values

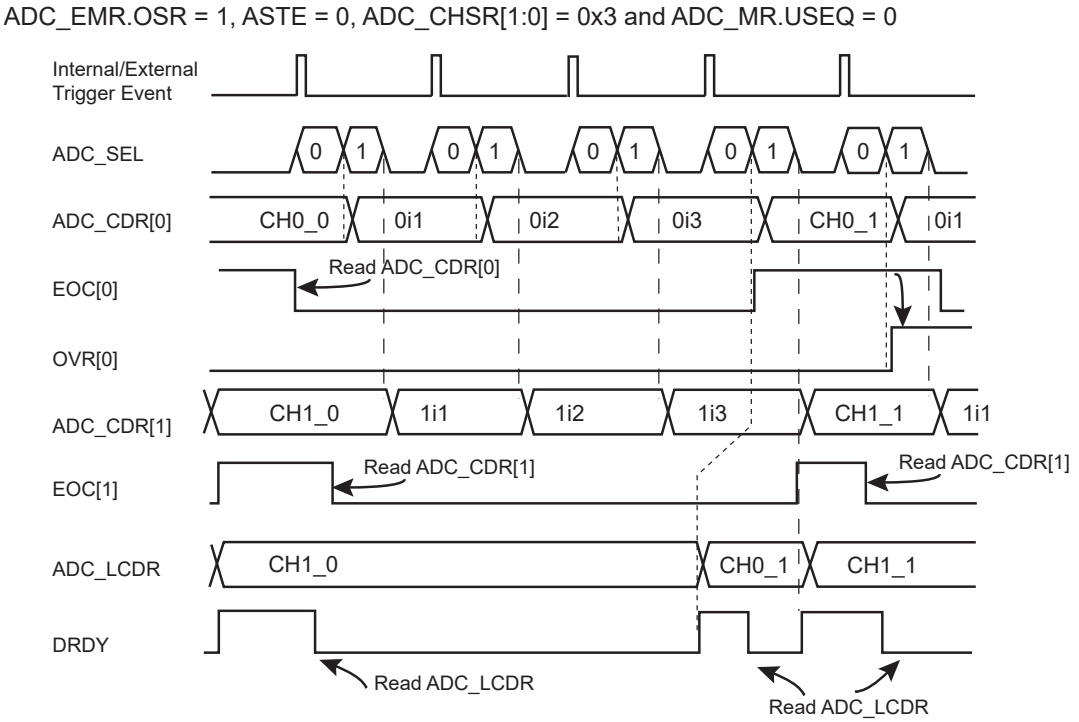
ADC_EMR.OSR Value	ADC_LCDR.LDATA Length	N Value	M Value	Full Scale Value	Maximum Value
0	12 bits	1	1	4095	4095
1	13 bits	4	2	8191	8190
2	14 bits	16	4	16383	16380
3	15 bits	64	8	32767	32760
4	16 bits	256	16	65535	65520

The average result is valid in ADC_CDRx (x corresponds to the index of the channel) only if the ADC_ISR.EOCn flag is set and if the ADC_OVER.OVREn flag is cleared. The average result for all channels is valid in ADC_LCDR only if ADC_ISR.DRDY is set and ADC_ISR.GOVRE is cleared.

Note that ADC_CDRs are not buffered. Therefore, when an averaging sequence is ongoing, the value in these registers changes after each averaging sample. However, overrun flags in ADC_OVER rise as soon as the first sample of an averaging sequence is received. Thus the previous averaged value is not read, even if the new averaged value is not ready.

Consequently, when an overrun flag rises in ADC_OVER, it means that the previous unread data is lost but it does not mean that this data has been overwritten by the new averaged value as the averaging sequence concerning this channel can still be ongoing.

© 2026 Microchip Technology Inc. and its subsidiaries



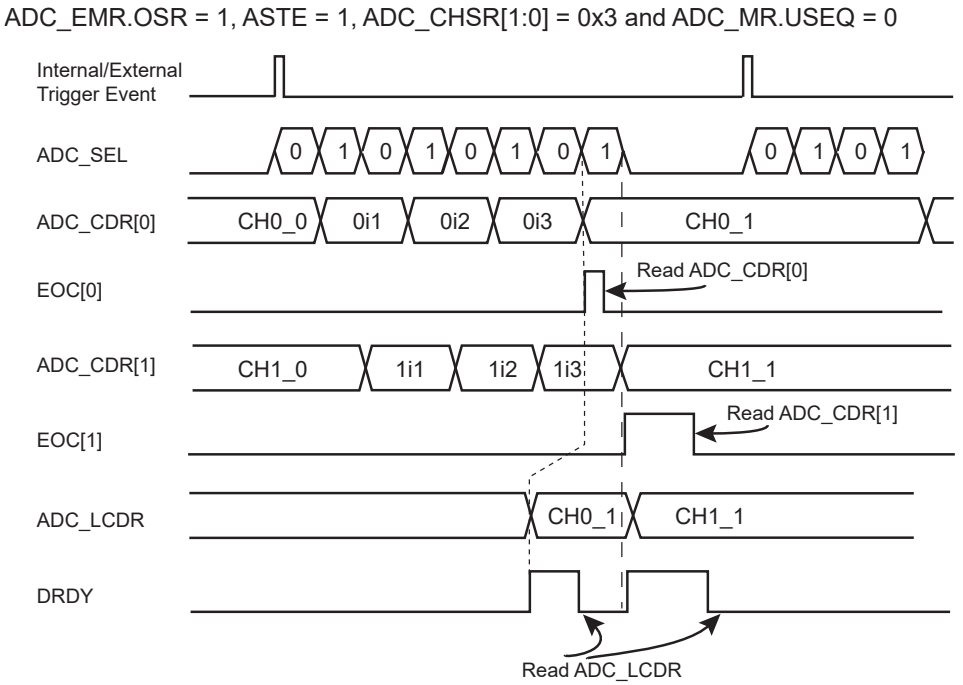
When an oversampling is performed, the maximum value that can be read on ADC_CDRx or ADC_LCDR is not the full-scale value, even if the maximum voltage is supplied on the analog input. See table above.

44.6.15.2.Averaging Function versus Trigger Events

The samples can be defined in different ways for the averaging function depending on the configuration of ADC_EMR.ASTE and ADC_MR.USEQ

When USEQ = 0, there are two possible ways to generate the averaging through the trigger event. If ADC_EMR.ASTE = 0, every trigger event generates one sample for each enabled channel, as described in the following figure. Therefore, four trigger events are required to obtain the result of averaging if OSR = 1.

Figure 44.11. Digital Averaging Function Waveforms Over Multiple Trigger Events



Note: ADC_SEL: Command to the ADC analog cell
0i1, 0i2, 0i3, 1i1, 1i2, 1i3 are intermediate results and CH0_0, CH0_1, CH1_0 and CH1_1 are final results of average function.

If ADC_EMR.ASTE = 1 and ADC_MR.USEQ = 0, the sequence to be converted, defined in ADC_CHSR, is automatically repeated n times (where n corresponds to the oversampling ratio defined in the ADC_EMR.OSR field). As a result, only one trigger is required to obtain the result of the averaging function as described in the following figure.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 44.12. Digital Averaging Function Waveforms on a Single Trigger Event

Note: ADC_SEL: Command to the ADC analog cell
0i1, 0i2, 0i3, 1i1, 1i2, 1i3 are intermediate results and CH0_0, CH0_1, CH1_0 and CH1_1 are final results of average function.

When USEQ = 1, the user can define the channel sequence to be converted by configuring ADC_SEQR1 and ADC_CHER so that channels are not interleaved during the averaging period. Under these conditions, a sample is defined for each end of conversion as described in the figure below.

When USEQ = 1 and ASTE = 1, OSR can be only configured to 1. Up to three channels can be converted in this mode. The averaging result will be placed in the corresponding ADC_CDRx and in ADC_LCDR for each trigger event. The ADC real sample rate remains the maximum ADC sample rate divided by 4.

It is important that the user sequence follows a specific pattern. The user sequence must be programmed in such a way that it generates a stream of conversion, where a same channel is successively converted.

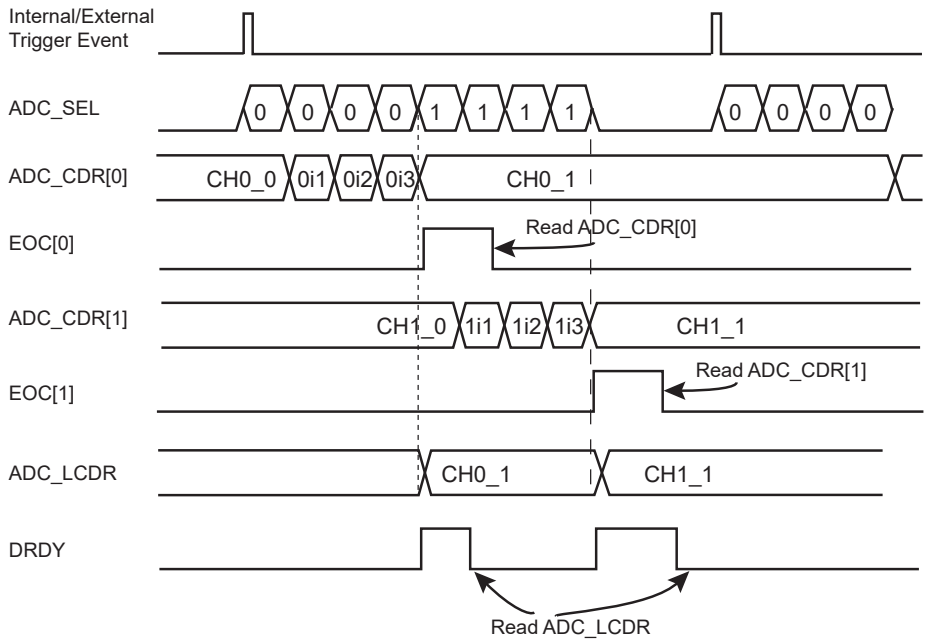


Table 44.5. Example Sequence Configurations (USEQ = 1, ASTE = 1, OSR = 1)

Register	Number of Channels Non-interleaved Averaging - Register Value		
	1 (e.g., CH0)	2 (e.g., CH0, CH1)	3 (e.g., CH0, CH1, CH2)
ADC_CHSR	0x0000_000F	0x0000_00FF	0x0000_0FFF
ADC_SEQR1	0x0000_0000	0x1111_0000	0x1111_0000

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 44.13. Digital Averaging Function Waveforms on a Single Trigger Event, Non-interleaved

ADC_EMR.OSR = 1, ASTE = 1, ADC_CHSR[7:0] = 0xFF and ADC_MR.USEQ = 1
ADC_SEQR1 = 0x1111_0000

Note: ADC_SEL: Command to the ADC analog cell
0i1, 0i2, 0i3, 1i1, 1i2, 1i3 are intermediate results and CH0_0, CH0_1, CH1_0 and CH1_1 are final results of average function.

44.6.16. Automatic Error Correction

The ADC features automatic error correction of conversion results. Offset and gain error corrections are available. The correction can be enabled for each channel and correction values (offset and gain) are .

To enable error correction, the corresponding ECORRx bit must be set in the Channel Error Correction register (ADC_CECR). The offset and gain values used to compensate the results are .

The error correction for channels used with the touchscreen is available in the ADC Touchscreen Correction Values register (ADC_TSCVR).

The ADC_EMR.ADCMODE field is used to configure a running mode of the ADC Normal mode, Offset Error mode, or Gain Error mode (see ADC_EMR). ADCMODE uses 3 internal references to be measured and to extract the offset and gain error from 3 point-measurement codes. If some references already exist on the final application connected to some input channel ADx, they can be used as a replacement of the ADCMODE to generate the 2 or 3 points of calibration and used to extract the GAINCORR and OFFSETCORR.

After a reset, the running mode of the ADC is Normal mode. Offset Error mode and Gain Error mode are used to determine values of offset compensation and gain compensation, respectively, to apply to conversion results. The table below provides formulas to obtain the compensation values, with:

- OFFSETCORR—the Offset Correction value. OFFSETCORR is a signed value.
- GAINCORR—the Gain Correction value
- GCi—the intermediate Gain Compensation value
- Gs—the value 15
- ConvValue—the value converted by the ADC (as returned in ADC_LCDR or ADC_CDR)

© 2026 Microchip Technology Inc. and its subsidiaries

- Resolution—the resolution used to process the conversion (either RESOLUTION, RESOLUTION+1 RESOLUTION+2, RESOLUTION+3, RESOLUTION+4).

Table 44.6. ADC Running Modes

ADC_EMR.ADCMODE	Mode	Description
0	Normal	Normal mode of operation to perform conversions
1	Offset Error	For unsigned conversions: OFFSETCORR = ConvValue – $2^{(\text{Resolution}} - 1)$
		For signed conversions: OFFSETCORR = ConvValue
2	Gain Error	GCi = ConvValue
3		$\text{GAINCORR} = \frac{3584}{\text{GCi} - \text{ConvValue}} \times 2^{(\text{Gs})}$

The final conversion result after error correction is obtained using the following formula:

$$\text{Corrected Data} = (\text{Converted Data} + \text{OFFSETCORR}) \times \frac{\text{GAINCORR}}{2^{(\text{Gs})}}$$

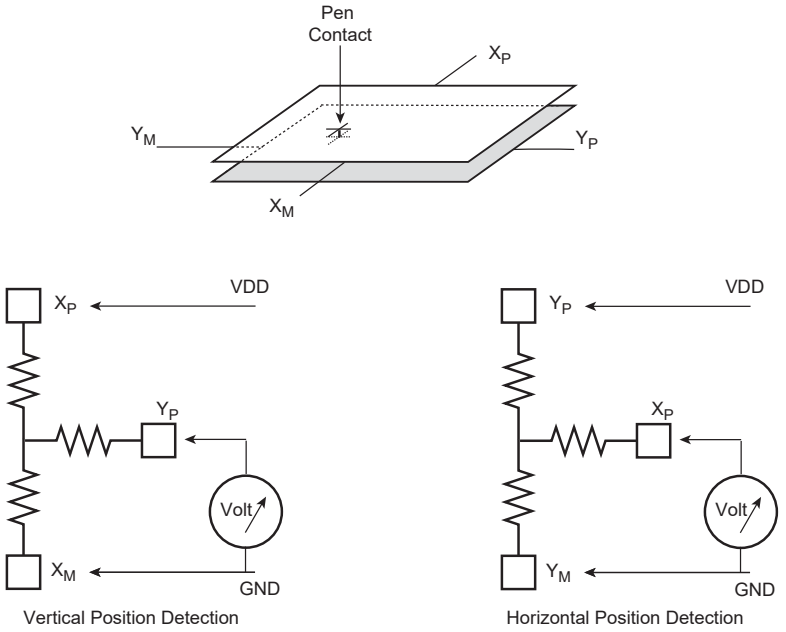
44.6.17. Touchscreen

44.6.17.1.Touchscreen Mode

The ADC_TSMR.TSMODE parameter is used to enable/disable the touchscreen functionality, to select the type of screen (4-wire or 5-wire) and, in the case of a 4-wire screen, to activate (or not) the pressure measurement.

In 4-wire mode, channels 0, 1, 2 and 3 must not be used for classic ADC conversions. Likewise, in 5-wire mode, channels 0, 1, 2, 3, and 4 must not be used for classic ADC conversions.

44.6.17.2.4-wire Resistive Touchscreen Principles



A resistive touchscreen is based on two resistive films, each one being fitted with a pair of electrodes, placed at the top and bottom on one film, and on the right and left on the other. In between, there is a layer acting as an insulator, but also enables contact when you press the screen. This is illustrated in the following figure.

The ADC Controller can perform the following tasks without external components:

- position measurement
- pressure measurement
- pen detection

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 44.14. Touchscreen Position Measurement

44.6.17.3.4-wire Position Measurement Method

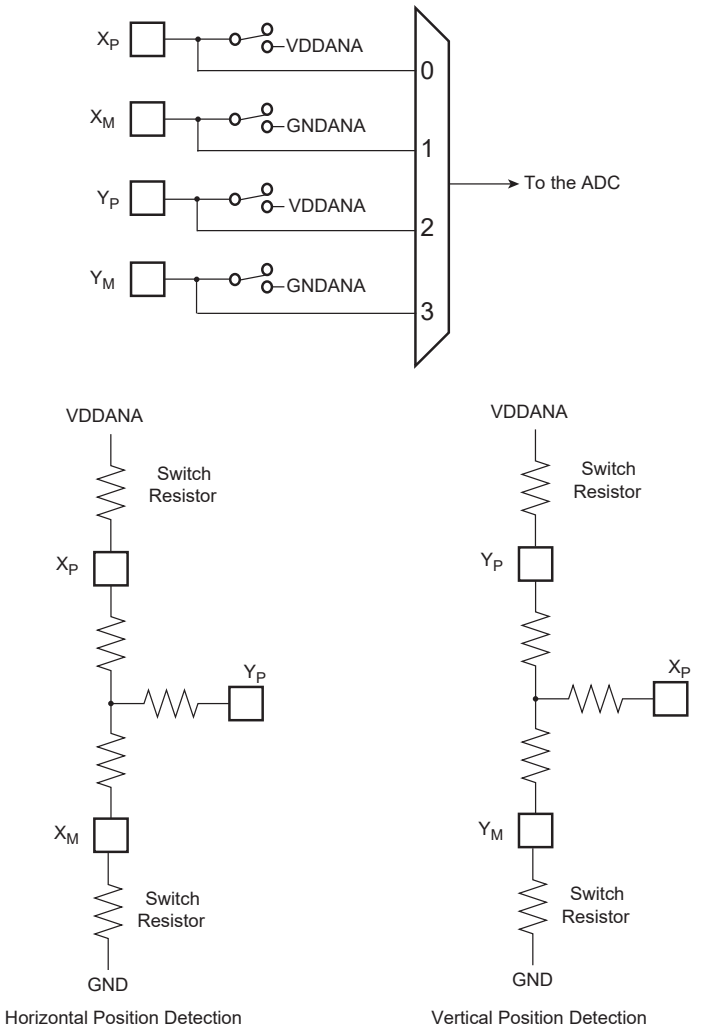
As shown in the above figure, to detect the position of a contact, a supply is first applied from top to bottom. Due to the linear resistance of the film, there is a voltage gradient from top to bottom. When a contact is performed on the screen, the voltage propagates at the point the two surfaces come into contact. If the input impedance on the right and left electrodes is high enough, the film intrinsic resistor does not affect this voltage.

For the horizontal direction, the same method is used, but by applying supply from left to right. The range depends on the supply voltage and on the loss in the switches that connect to the top and bottom electrodes.

In an ideal world (linear, with no loss through switches), the horizontal position is equal to:

VY_M / VDD or VY_P / VDD.

The implementation with on-chip power switches is shown in the figure below. The voltage measurement at the output of the switch compensates for the switches loss.



It is possible to correct for switch loss by performing the operation:

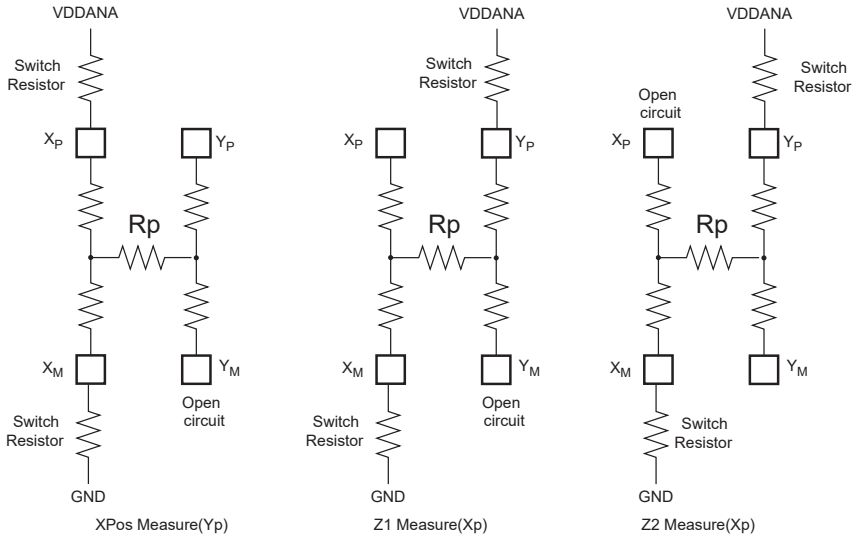
$[VY_P - VX_M] / [VX_P - VX_M]$.

This requires additional measurements, as shown in the figure below.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 44.15. Touchscreen Switches Implementation

44.6.17.4.4-wire Pressure Measurement Method



The method to measure the pressure (Rp) applied to the touchscreen is based on the known resistance of the X-Panel resistance (Rxp).

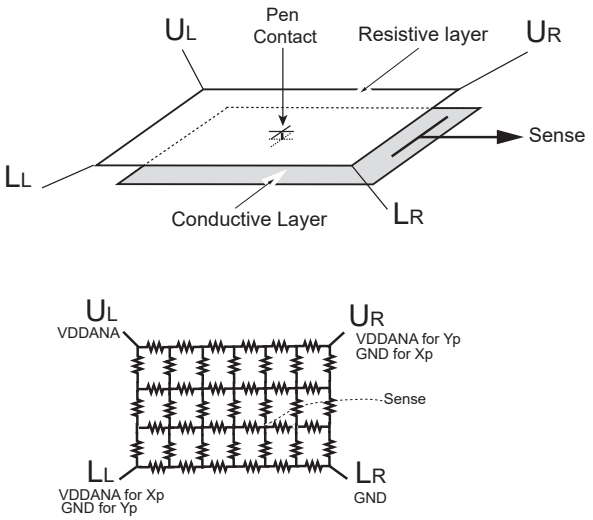
Three conversions (Xpos,Z1,Z2) are necessary to determine the value of Rp (Zaxis resistance).

$Rp = Rxp \times (Xpos/1024) \times [(Z2/Z1)-1]$

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 44.16. Pressure Measurement

44.6.17.5.5-wire Resistive Touchscreen Principles



To make a 5-wire touchscreen, a resistive layer with a contact point at each corner and a conductive layer are used.

The 5-wire touchscreen differs from the 4-wire type mainly in that the voltage gradient is applied only to one layer, the resistive layer, while the other layer is the sense layer for both measurements.

The measurement of the X position is obtained by biasing the upper left corner and lower left corner to VDDANA and the upper right corner and lower right to ground.

To measure along the Y axis, bias the upper left corner and upper right corner to VDDANA and bias the lower left corner and lower right corner to ground.

Figure 44.17. 5-Wire Principle

44.6.17.6.5-wire Position Measurement Method

In an application only monitoring clicks, 100 points per second is typically needed. For handwriting or motion detection, the number of measurements to consider is approximately 200 points per second. This must take into account that multiple measurements are included (over sampling, filtering) to compute the correct point.

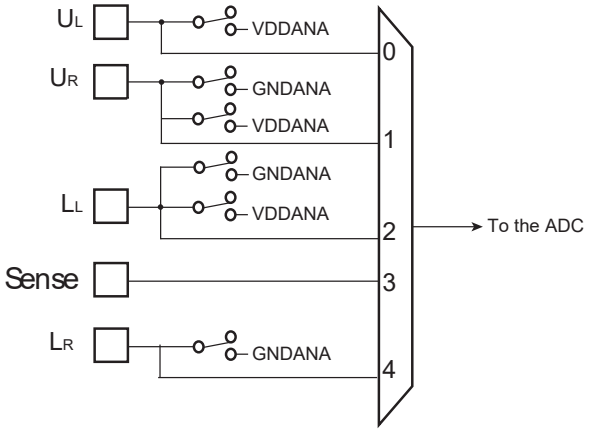
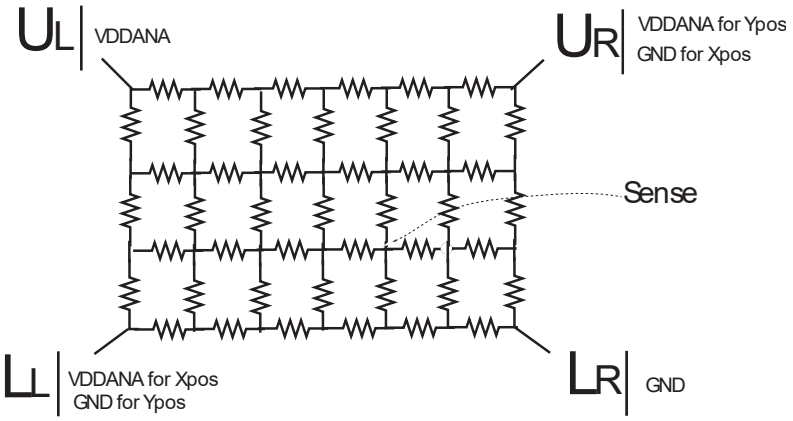
The 5-wire touchscreen panel works by applying a voltage at the corners of the resistive layer and measuring the vertical or horizontal resistive network with the sense input. The ADC converts the voltage measured at the point the panel is touched.

A measurement of the Y position of the pointing device is made by:

- Connecting Upper left (UL) and upper right (UR) corners to VDDANA
- Connecting Lower left (LL) and lower right (LR) corners to ground.



The voltage measured is determined by the voltage divider developed at the point of touch (Y position) and the SENSE input is converted by ADC.



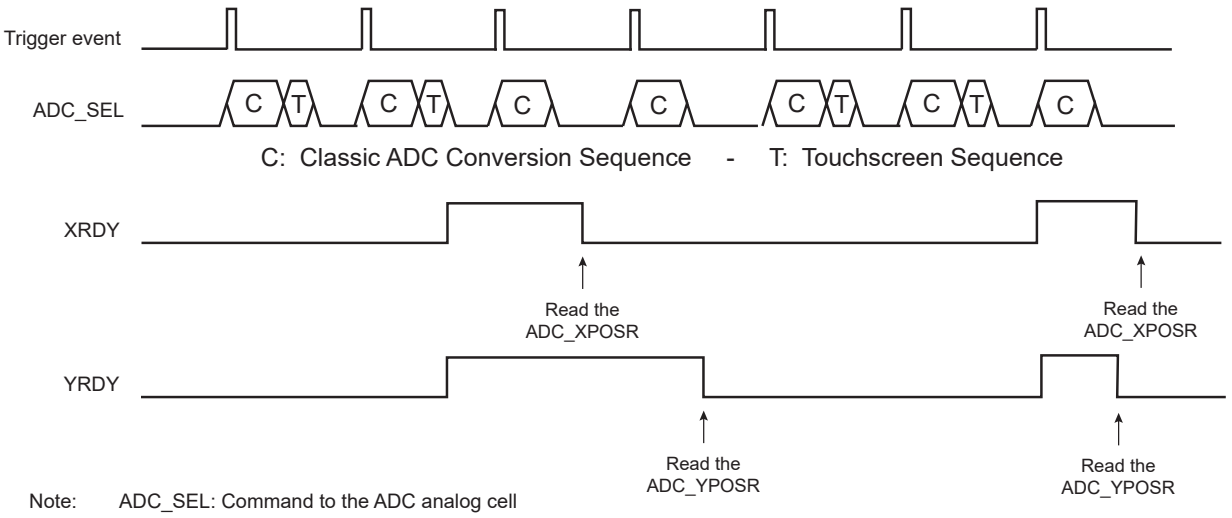
A measurement of the X position of the pointing device is made by:

- Connecting the upper left (UL) and lower left (LL) corners to ground
- Connecting the upper right and lower right corners to VDDANA.

The voltage measured is determined by the voltage divider developed at the point of touch (X position) and the SENSE input is converted by ADC.

Figure 44.18. Touchscreen Switches Implementation

44.6.17.7.Sequence and Noise Filtering



The ADC Controller can manage ADC conversions and touchscreen measurement. On each trigger event the sequence of ADC conversions is performed as described in Sleep Mode and Conversion Sequencer. The touchscreen measure frequency can be specified in number of trigger events by writing the ADC_TSMR.TSFREQ parameter. An internal counter counts triggers up to TSFREQ, and

© 2026 Microchip Technology Inc. and its subsidiaries

every time it rolls out, a touchscreen sequence is appended to the classic ADC conversion sequence (see figure below).

Additionally the user can average multiple touchscreen measures by writing the ADC_TSMR.TSAV parameter. This can be 1, 2, 4 or 8 measures performed on consecutive triggers as illustrated in the figure below. Consequently, the ADC_TSMR.TSFREQ parameter must be greater than or equal to the ADC_TSMR.TSAV parameter.

Figure 44.19. Insertion of Touchscreen Sequences (TSFREQ = 2; TSAV = 1)

44.6.17.8.Measured Values, Registers and Flags

As soon as the controller finishes the Touchscreen sequence, XRDY, YRDY and PRDY are set and can generate an interrupt. These flags can be read in the Interrupt Status register (ADC_ISR). They are reset independently by reading in the ADC Touchscreen X Position register (ADC_XPOSR), the ADC Touchscreen Y Position register (ADC_YPOSR) and the ADC Touchscreen Pressure register (ADC_PRESSR).

ADC_XPOSR presents XPOS (VX - VXmin) on its LSB and XSCALE (VXMAX - VXmin) aligned on the 16th bit.

ADC_YPOSR presents YPOS (VY - VYmin) on its LSB and YSCALE (VYMAX - VYmin) aligned on the 16th bit.

To improve the quality of the measure, the user must calculate XPOS/XSCALE and YPOS/YSCALE.

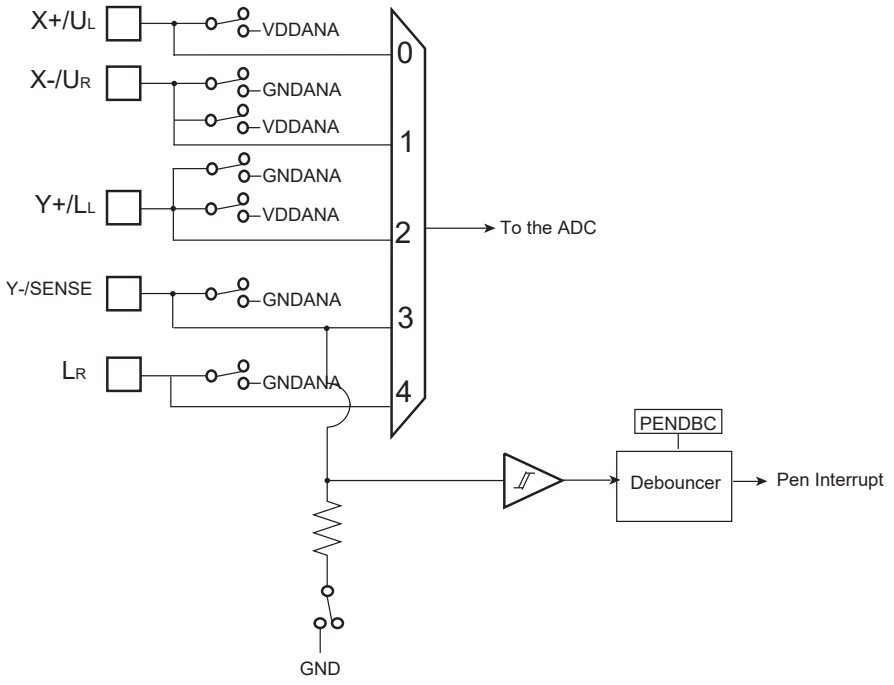
VXMAX, VXmin, VYMAX, and VYmin are measured at the first start-up of the controller. These values can change during use, so it can be necessary to refresh them. Refresh can be done by writing '1' in the ADC_CR.TSCALIB field.

ADC_PRESSR presents Z1 on its LSB and Z2 aligned on the 16th bit. See 4-wire Pressure Measurement Method.

44.6.17.9.Pen Detect Method

When there is no contact, it is not necessary to perform a conversion. However, it is important to detect a contact by keeping the power consumption as low as possible.

The implementation polarizes one panel by closing the switch on (X_P/U_L) and ties the horizontal panel by an embedded resistor connected to Y_M / Sense. This resistor is enabled by a fifth switch. Since there is no contact, no current is flowing and there is no related power consumption. As soon as a contact occurs, a current is flowing in the Touchscreen and a Schmitt trigger detects the voltage in the resistor.



© 2026 Microchip Technology Inc. and its subsidiaries

The Touchscreen Interrupt configuration is entered by programming ADC_TSMR.PENDET. If this bit is written at 1, the controller samples the pen contact state when it is not converting and waiting for a trigger.

To complete the circuit, a programmable debouncer is placed at the output of the Schmitt trigger. This debouncer is programmable up to 2^{15} ADC clock periods. The debouncer length can be selected by programming the ADC_TSMR.PENDBC field.

Due to the analog switch's structure, the debouncer circuitry is only active when no conversion (touchscreen or classic ADC channels) is in progress. Thus, if the time between the end of a conversion sequence and the arrival of the next trigger event is lower than the debouncing time configured on ADC_TSMR.PENDBC, the debouncer will not detect any contact.

Figure 44.20. Touchscreen Pen Detect

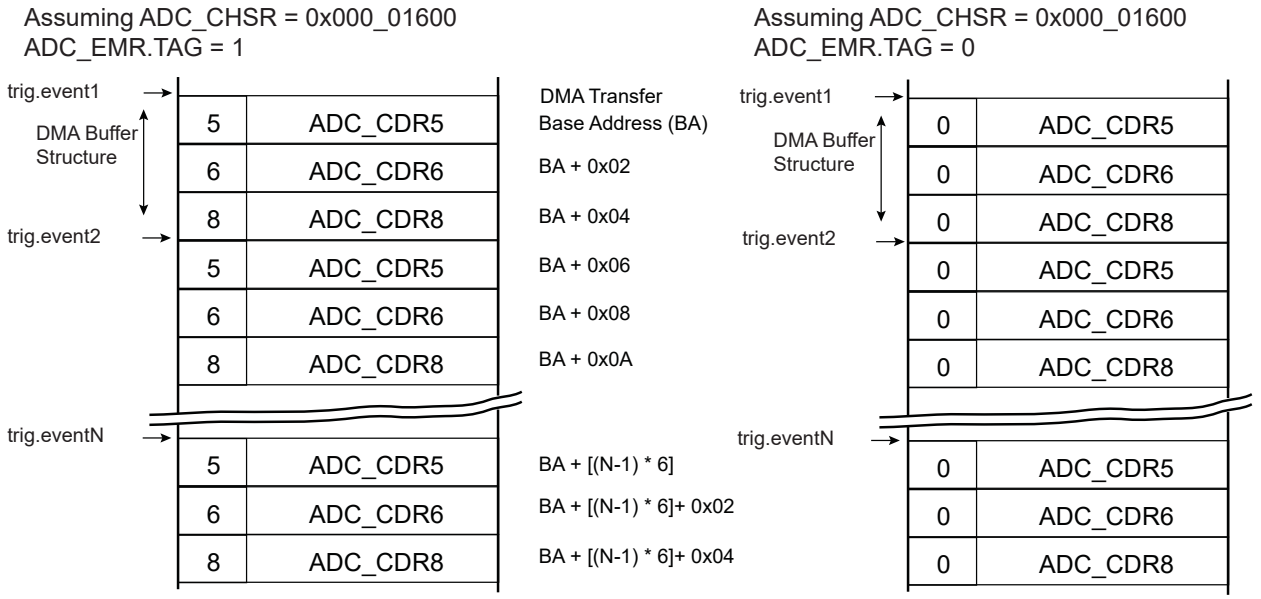
The touchscreen pen detect can be used to generate an ADC interrupt to wake up the system. The pen detect generates two types of status, reported in ADC_ISR:

- ADC_ISR.PEN is set as soon as a contact exceeds the debouncing time as defined by ADC_TSMR.PENDBC and remains set until ADC_ISR is read.
- ADC_ISR.NOPEN is set as soon as no current flows for a time over the debouncing time as defined by PENDBC and remains set until ADC_ISR is read.

Both bits are automatically cleared as soon as ADC_ISR is read, and can generate an interrupt by writing ADC_IER.

Moreover, the rising of either one of them clears the other, they cannot be set at the same time.

ADC_ISR.PENS shows the current status of the pen contact.



44.6.18. Buffer Structure

The DMA read channel is triggered each time a new data is stored in ADC_LCDR. The same data structure is repeatedly stored in ADC_LCDR each time a trigger event occurs. Depending on user mode of operation (ADC_MR, ADC_CHSR, ADC_SEQR1, ADC_TSMR) the structure differs. Each data read to DMA buffer, carried on a half-word (16-bit), consists of last converted data right-aligned and

© 2026 Microchip Technology Inc. and its subsidiaries

when the ADC_EMR.TAG is set, the four most significant bits are carrying the channel number thus allowing an easier postprocessing in the DMA buffer or better checking the DMA buffer integrity.

Figure 44.21. Buffer Structure

As soon as touchscreen conversions are required, the pen detection function can help the postprocessing of the buffer. See Pen Detection Status.

44.6.18.1.Classic ADC Channels Only (Touchscreen Disabled)

When no touchscreen conversion is required (i.e., ADC_TSMR.TSMODE = 0), the data structure within the buffer is defined by ADC_MR, ADC_CHSR, ADC_SEQR1. See figure Buffer Structure.

If the user sequence is not used (i.e., ADC_MR.USEQ is cleared) then only the value of ADC_CHSR defines the data structure. For each trigger event, enabled channels will be consecutively stored in ADC_LCDR and automatically read to the buffer.

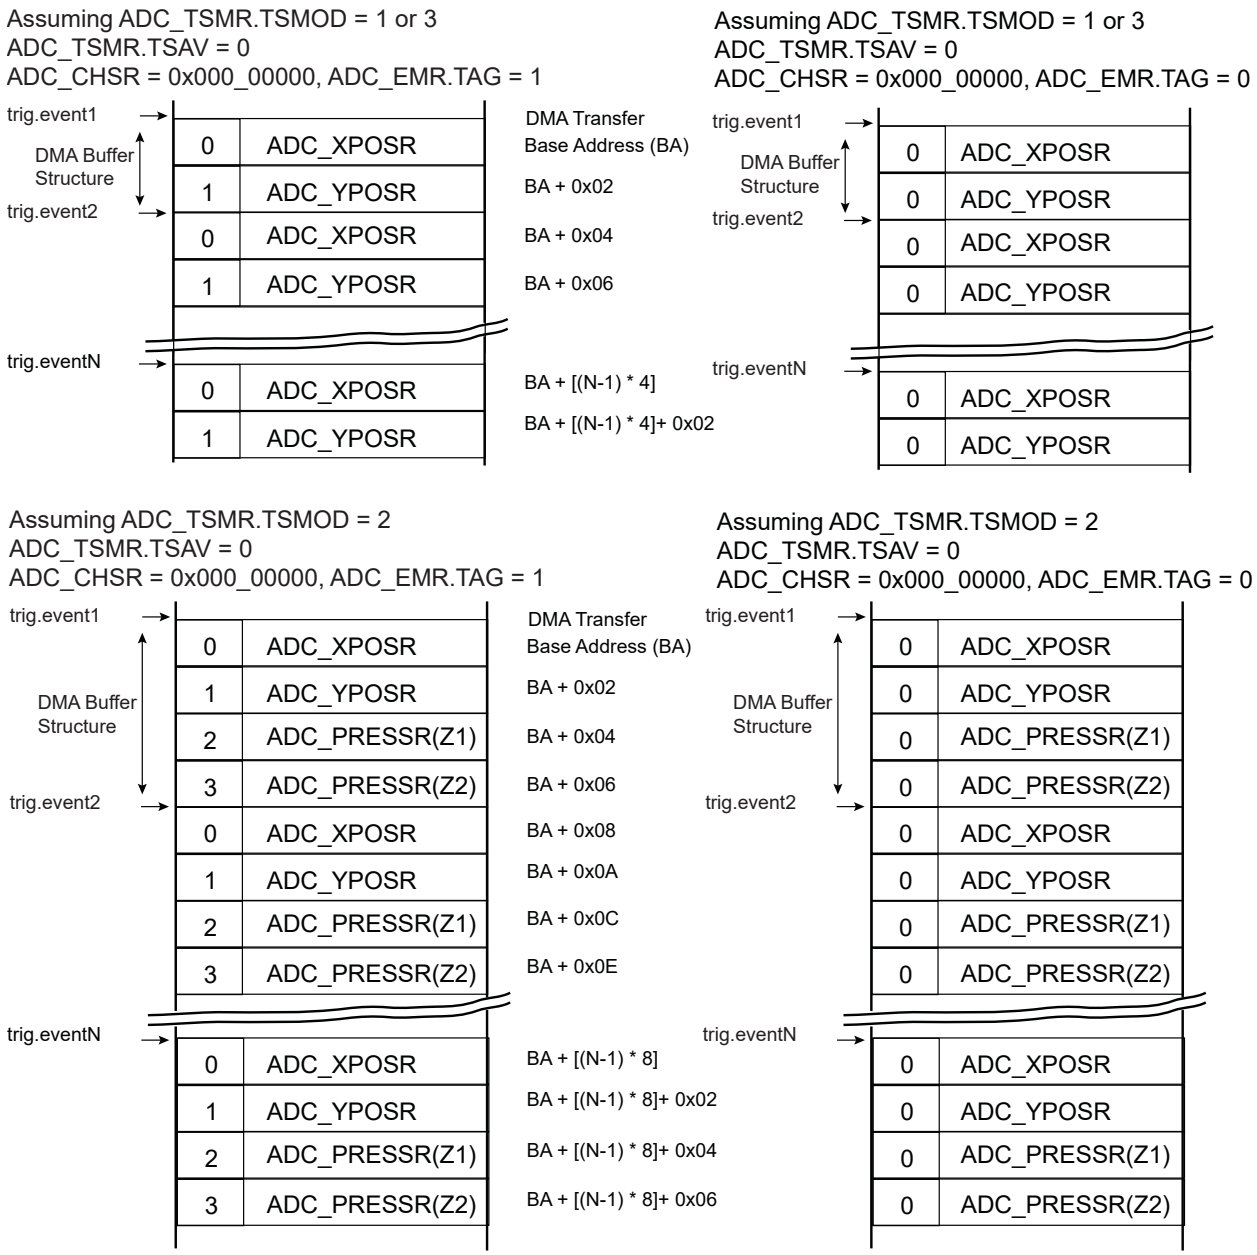
When the user sequence is configured (i.e., ADC_MR.USEQ is set) not only does ADC_CHSR modify the data structure of the buffer, but ADC_SEQR1 may modify the data structure of the buffer as well.

44.6.18.2.Touchscreen Channels Only

When only touchscreen conversions are required (i.e., TSMODE ≠ 0 in ADC_TSMR and ADC_CHSR equals 0), the structure of data within the buffer is defined by ADC_TSMR.

When TSMODE = 1 or 3, each trigger event adds two half-words in the buffer (assuming TSAV = 0), first half-word being ADC_XPOSR.XPOS, then ADC_YPOSR.YPOS. If TSAV/TSFREQ ≠ 0, the data structure remains unchanged. Not all trigger events add data to the buffer.

When TSMODE = 2, each trigger event adds four half-words to the buffer (assuming TSAV = 0), first half-word being ADC_XPOSR.XPOS, followed by ADC_YPOSR.YPOS and finally ADC_PRESSR.Z1, followed by ADC_PRESSR.Z2.



When ADC_EMR.TAG is set, the CHNB field (four most significant bits of ADC_LCDR) is cleared when ADC_XPOSR.XPOS is transmitted and set when ADC_YPOSR.YPOS is transmitted, allowing an easier post-processing of the buffer or a better checking of the buffer integrity. In case 4-wire with Pressure mode is selected, the Z1 value is transmitted to the buffer along with tag set to 2 and Z2 is tagged with value 3.

XSCALE and YSCALE (calibration values) are not transmitted to the buffer because they are supposed to be constant and moreover only measured at the very first start-up of the controller or upon user request.

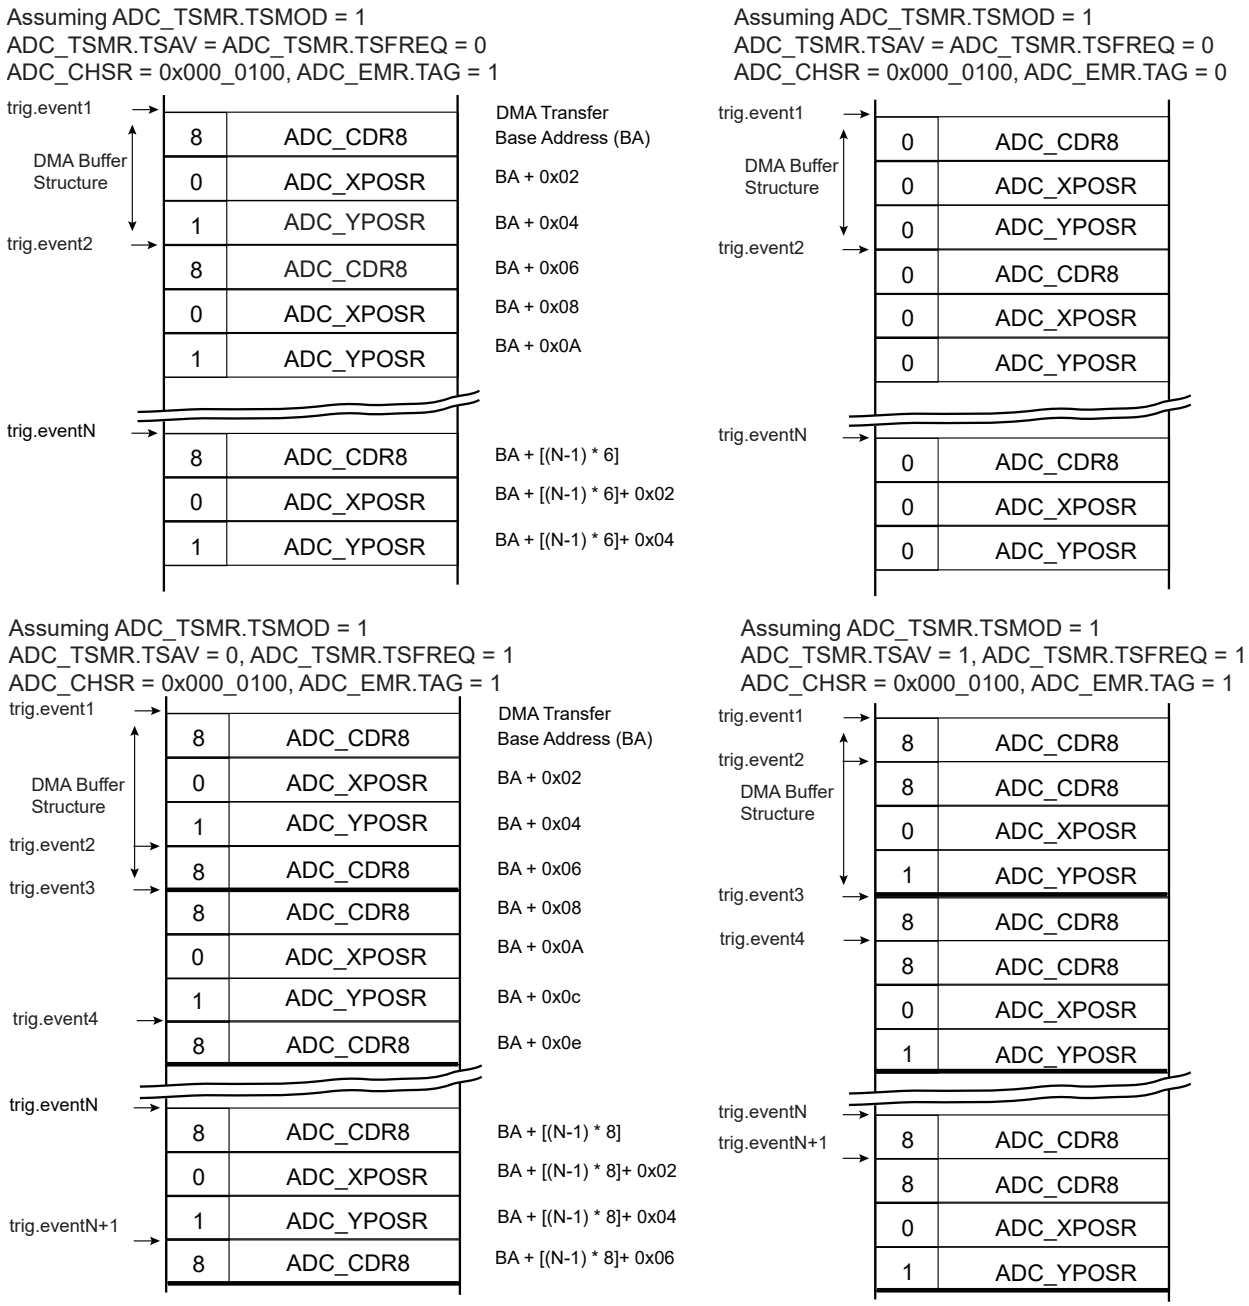
© 2026 Microchip Technology Inc. and its subsidiaries

There is no change in buffer structure whatever the value of PENDET.ADC_TSMR, but it is recommended to use the pen detection function for buffer postprocessing (see Pen Detection Status).

Figure 44.22. Buffer Structure When Only Touchscreen Channels are Enabled

44.6.18.3.Interleaved Channels

When both classic ADC channels (CH4/CH5 up to CH8 are set in ADC_CHSR) and touchscreen conversions are required (TSMODE ≠ 0 in ADC_TSMR), the structure of the buffer differs according to the ADC_TSMR.TSAV and ADC_TSMR.TSFREQ values.



If TSFREQ ≠ 0, not all events generate touchscreen conversions, therefore the buffer structure is based on 2^{TSFREQ} trigger events. Given a TSFREQ value, the location of touchscreen conversion results depends on TSAV value.

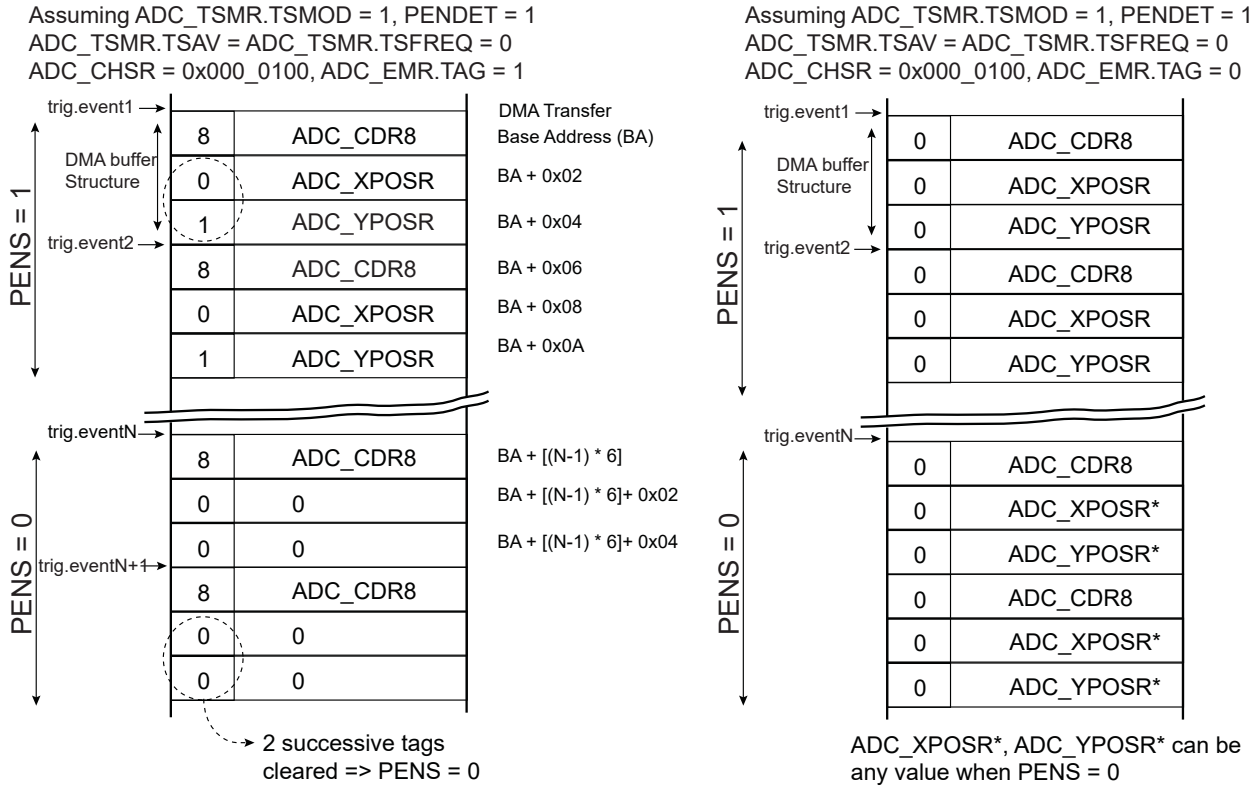
When TSFREQ = 0, TSAV must equal 0.

© 2026 Microchip Technology Inc. and its subsidiaries

There is no change in buffer structure whatever the value of ADC_TSMR.PENDET, but it is recommended to use the pen detection function for buffer post-processing (see Pen Detection Status).

Figure 44.23. Buffer Structure When Classic ADC and Touchscreen Channels are Interleaved

44.6.18.4.Pen Detection Status



If the pen detection measure is enabled (ADC_TSMR.PENDET is set), the XPOS, YPOS, Z1, Z2 values transmitted to the buffer through ADC_LCDR are cleared (including the CHNB field), if the ADC_ISR.PENS flag is 0. When the ADC_ISR.PENS flag is set, XPOS, YPOS, Z1, Z2 are normally transmitted.

© 2026 Microchip Technology Inc. and its subsidiaries

Therefore, using pen detection together with tag function eases the post-processing of the buffer, especially to determine which touchscreen converted values correspond to a period of time when the pen was in contact with the screen.

When the pen detection is disabled or the tag function is disabled, XPOS, YPOS, Z1, Z2 are normally transmitted without tag and no relationship can be found with pen status, thus post-processing may not be easy.

Figure 44.24. Buffer Structure With and Without Pen Detection Enabled

44.6.19. Fault Event

The ADC Controller internal fault output is directly connected to the PWM fault input. The fault event may be asserted depending on the configuration of ADC_EMR, ADC_CWR, ADC_LCMR and ADC_LCCWR and converted values.

Two types of comparison can trigger a comparison event (fault output pulse):

- The first comparison type is based on ADC_LCCWR settings, i.e., on all converted channels except the last one;
- The second comparison type is linked to the last channel.

As an example, overcurrent and temperature exceeding limits can trigger a fault to PWM.

When the comparison event occurs, the ADC fault output generates a pulse of one peripheral clock cycle to the PWM fault input. This fault line can be enabled or disabled within PWM. Should it be activated and asserted by the ADC Controller, the PWM outputs are immediately placed in a safe state (pure combinational path). Note that the ADC fault output connected to the PWM is not the COMPE bit. Thus the Fault mode (FMOD) within the PWM configuration must be FMOD = 1.

© 2026 Microchip Technology Inc. and its subsidiaries

44.6.20. Register Write Protection

To prevent any single software error from corrupting ADC behavior, certain registers in the address space can be write-protected by setting the bits WPEN and WPITEN in the ADC_WPMR.

If a write access to the protected registers is detected, the WPVS flag in the ADC_WPSR is set and the field WPVSRC indicates the register in which the write access has been attempted.

The WPVS flag is automatically reset by reading ADC_WPSR.

The following registers are write-protected when ADC_WPMR.WPEN is set:

- ADC Mode Register
- ADC Channel Sequence 1 Register
- ADC Channel Enable Register
- ADC Channel Disable Register
- ADC Last Channel Trigger Mode Register
- ADC Last Channel Compare Window Register
- ADC Extended Mode Register
- ADC Compare Window Register
- ADC Channel Configuration Register
- ADC Analog Control Register
- ADC Pseudo-Differential Register
- ADC_Touchscreen Mode Register
- ADC Trigger Register
- ADC Correction Values Register
- ADC Channel Error Correction Register
- ADC Touchscreen Correction Values Register
  The following registers are write-protected when ADC_WPMR.WPITEN is set:
- ADC Interrupt Enable Register
- ADC Interrupt Disable Register

The following register is write-protected when ADC_WPMR.WPCTEN is set:

- ADC Control Register

44.7.1. ADC Control Register

Name: ADC_CR
Offset: 0x00
Reset: –
Property: Write-only

This register can only be written if the WPCTEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
				CMPRST		TSCALIB	START	SWRST
Access				W		W	W	W
Reset				–		–	–	–

Bit 4 – CMPRST Comparison Restart

Value	Description
0	No effect.
1	Stops the conversion result storage until the next comparison match.

Bit 2 – TSCALIB Touchscreen Calibration

If conversion is in progress, the calibration sequence starts at the beginning of a new conversion sequence. If no conversion is in progress, the calibration sequence starts at the second conversion sequence located after the TSCALIB command (Sleep mode, waiting for a trigger event).
TSCALIB measurement sequence does not affect the Last Converted Data register (ADC_LCDR).

Value	Description
0	No effect.
1	Programs screen calibration (VDD/GND measurement)

Bit 1 – START Start Conversion

Value	Description
0	No effect.
1	Triggers a single sequence of analog-to-digital conversions if ADC_TRGR.TRGMOD=0.

Bit 0 – SWRST Software Reset

Value	Description
0	No effect.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	Resets the ADC.

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.2. ADC Mode Register

Name: ADC_MR
Offset: 0x04
Reset: 0x20000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	USEQ	MAXSPEED	TRANSFER[1:0]		TRACKTIM[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	1	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16
	ANACH				STARTUP[3:0]			
Access	R/W				R/W	R/W	R/W	R/W

Access		R/W	R/W		R/W	R/W	R/W	
Reset		0	0		0	0	0	

Bit 31 – USEQ User Sequence Enable

Value	Name	Description
0	NUM_ORDER	Normal mode: the controller converts channels in a simple numeric order depending only on the channel index.
1	REG_ORDER	User Sequence mode: the sequence respects what is defined in ADC_SEQR1 and can be used to convert the same channel several times.

Bit 30 – MAXSPEED Maximum Sampling Rate Enable in Freerun Mode
This bit should always be set to 1.

Bits 29:28 – TRANSFER[1:0] Transfer Time
The TRANSFER field must be set to 2 to guarantee the optimal transfer time.

Bits 27:24 – TRACKTIM[3:0] Tracking Time

ADC_EMR.TRACKX	TRACKTIM					
	0	1	2	3 to 10	11 to 12	13 to 15
0	6 x t_{ADCCLK}				7 x t_{ADCCLK}	(TRACKTIM-5) x t_{ADCCLK}
1	6 x t_{ADCCLK}		7 x t_{ADCCLK}	([4 x (TRACKTIM+1)] - 6) x t_{ADCCLK}		

Bit 23 – ANACH Analog Change

Value	Name	Description
0	NONE	No analog change on channel switching: DIFF0 is used for all channels.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
1	ALLOWED	Allows different analog settings for each channel. .

Bits 19:16 – STARTUP[3:0] Start-Up Time

Value	Name	Description
0	SUT0	0 periods of ADCCLK
1	SUT8	8 periods of ADCCLK
2	SUT16	16 periods of ADCCLK
3	SUT24	24 periods of ADCCLK
4	SUT64	64 periods of ADCCLK
5	SUT80	80 periods of ADCCLK
6	SUT96	96 periods of ADCCLK
7	SUT112	112 periods of ADCCLK
8	SUT512	512 periods of ADCCLK
9	SUT576	576 periods of ADCCLK
10	SUT640	640 periods of ADCCLK
11	SUT704	704 periods of ADCCLK
12	SUT768	768 periods of ADCCLK
13	SUT832	832 periods of ADCCLK
14	SUT896	896 periods of ADCCLK
15	SUT960	960 periods of ADCCLK

Bits 15:8 – PRESCAL[7:0] Prescaler Rate Selection

PRESCAL = ($f_{peripheral\ clock}$ / (2 × f_{ADCCLK})) – 1.

Bit 6 – FWUP Fast Wake-Up

Value	Name	Description
0	OFF	If SLEEP is 1, then both ADC core and reference voltage circuitry are off between conversions.
1	ON	If SLEEP is 1, then Fast Wake-Up Sleep mode: the voltage reference is on between conversions and ADC core is off.

Bit 5 – SLEEP Sleep Mode

Value	Name	Description
0	NORMAL	Normal mode: the ADC core and reference voltage circuitry are kept on between conversions.
1	SLEEP	Sleep mode: the wake-up time can be modified by programming the FWUP bit.

Bits 3:1 – TRGSEL[2:0] Trigger Selection

The trigger selection can be performed only if ADC_TRGR.TRGMOD = 1, 2 or 3.

Value	Name	Description
0	ADC_TRIG0	ADTRG
1	ADC_TRIG1	TIOA0
2	ADC_TRIG2	TIOA1
3	ADC_TRIG3	TIOA2
4	ADC_TRIG4	RTCOUT1
5	ADC_TRIG5	Reserved
6	ADC_TRIG6	Reserved
7	ADC_TRIG7	Reserved

44.7.3. ADC Channel Sequence 1 Register

Name: ADC_SEQR1
Offset: 0x08
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	USCH8[3:0]				USCH7[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	USCH6[3:0]				USCH5[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	USCH4[3:0]				USCH3[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	USCH2[3:0]				USCH1[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 0:3, 4:7, 8:11, 12:15, 16:19, 20:23, 24:27, 28:31 – USCHx User Sequence Number x
This register can be used only if the ADC_MR.USEQ field is set to '1'.
Any USCHx field is processed only if the ADC_CHSR.CHx-1 bit reads logical '1', else any value written in USCHx does not add the corresponding channel in the conversion sequence.
Configuring the same value in different fields leads to multiple samples of the same channel during the conversion sequence. This can be done consecutively, or not, according to user needs.
Example: for each trigger event, to obtain the "CH3 CH1 CH0 CH4 CH4" conversion sequence, use the following settings:
ADC_SEQR1.USCH1=3, ADC_CHSR.CH0=1
ADC_SEQR1.USCH2=1, ADC_CHSR.CH1=1
ADC_SEQR1.USCH3=0, ADC_CHSR.CH2=1
ADC_SEQR1.USCH4=4, ADC_CHSR.CH3=1
ADC_SEQR1.USCH5=4, ADC_CHSR.CH4=1

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.4. ADC Channel Enable Register

Name: ADC_CHER
Offset: 0x10
Reset: –
Property: Write-only

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	CH7	CH6	CH5	CH4	CH3	CH2	CH1	CH0
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bits 0, 1, 2, 3, 4, 5, 6, 7 – CHx Channel x Enable
If ADC_MR.USEQ = 1, CHx corresponds to the enable of sequence number x+1 described in ADC_SEQR1 (for example, CH0 enables sequence number USCH1).

Value	Description
0	No effect.
1	Enables the corresponding channel.

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.5. ADC Channel Disable Register

Name: ADC_CHDR
Offset: 0x14
Reset: –
Property: Write-only

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	CH7	CH6	CH5	CH4	CH3	CH2	CH1	CH0
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bits 0, 1, 2, 3, 4, 5, 6, 7 – CHx Channel x Disable

WARNING If the corresponding channel is disabled during a conversion or if it is disabled and then reenabled during a conversion, its associated data and corresponding EOCx and GOVRE flags in ADC_ISR and OVREx flags in ADC_OVER are unpredictable

Value	Description
0	No effect.
1	Disables the corresponding channel.

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.6. ADC Channel Status Register

Name: ADC_CHSR
Offset: 0x18
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	CH7	CH6	CH5	CH4	CH3	CH2	CH1	CH0
Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0

Bits 0, 1, 2, 3, 4, 5, 6, 7 – CHx Channel x Status

Value	Description
0	The corresponding channel (or part of sequence, see ADC_SEQyR.USCHx field) is disabled.
1	The corresponding channel (or part of sequence, see ADC_SEQyR.USCHx field) is enabled. As an example, when ADC_MR.USEQ=1 and ADC_CHSR.CH2=1, the channel configured in ADC_SEQ1R.USCH3 is part of the sequence of conversions.

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.7. ADC Last Converted Data Register

Name: ADC_LCDR
Offset: 0x20
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
				CHNBOSR[4:0]				
Access				R	R	R	R	R
Reset				0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	LDATA[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	LDATA[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 28:24 – CHNBOSR[4:0] Channel Number in Oversampling Mode
Indicates the last converted channel when the ADC_EMR.TAG bit is set and the ADC_EMR0.OSR field is not equal to 0. If the ADC_EMR.TAG bit is not set, CHNBOSR = 0.

Bits 15:0 – LDATA[15:0] Last Data Converted
The analog-to-digital conversion data is placed into this register at the end of a conversion and remains until a new conversion is completed.
If OSR = 0 and TAG = 1 in ADC_EMR, the 4 MSBs of LDATA carry the channel number to obtain a packed system memory buffer made of 1 converted data stored in a halfword (16-bit) instead of 1 converted data in a 32-bit word, thus dividing by 2 the size of the memory buffer.

44.7.8. ADC Interrupt Enable Register

Name: ADC_IER
Offset: 0x24
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the ADC Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
		NOPEN	PEN			COMPE	GOVRE	DRDY
Access		W	W			W	W	W
Reset		–	–			–	–	–

Bit	23	22	21	20	19	18	17	16
		PRDY	YRDY	XRDY	LCCHG			
Access		W	W	W	W			
Reset		–	–	–	–			

Bit	15	14	13	12	11	10	9	8
Access

Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bit 30 – NOPEN No Pen Contact Interrupt Enable

Bit 29 – PEN Pen Contact Interrupt Enable

Bit 26 – COMPE Comparison Event Interrupt Enable

Bit 25 – GOVRE General Overrun Error Interrupt Enable

Bit 24 – DRDY Data Ready Interrupt Enable

Bit 22 – PRDY Touchscreen Measure Pressure Ready Interrupt Enable

Bit 21 – YRDY Touchscreen Measure YPOS Ready Interrupt Enable

Bit 20 – XRDY Touchscreen Measure XPOS Ready Interrupt Enable

Bit 19 – LCCHG Last Channel Change Interrupt Enable

Bits 0, 1, 2, 3, 4, 5, 6, 7 – EOCx End of Conversion Interrupt Enable x

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.9. ADC Interrupt Disable Register

Name: ADC_IDR
Offset: 0x28
Reset: –
Property: Write-only

This register can only be written if the WPITEN bit is cleared in the ADC Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
		NOPEN	PEN			COMPE	GOVRE	DRDY
Access		W	W			W	W	W
Reset		–	–			–	–	–

Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit 31 – PENS Pen Detect Status
PENS is not a source of interruption.

Value	Description
0	The pen does not press the screen.
1	The pen presses the screen.

Bit 30 – NOPEN No Pen Contact (cleared on read)

Value	Description
0	No loss of pen contact since the last read of ADC_ISR.
1	At least one loss of pen contact since the last read of ADC_ISR.

Bit 29 – PEN Pen contact (cleared on read)

Value	Description
0	No pen contact since the last read of ADC_ISR.
1	At least one pen contact since the last read of ADC_ISR.

Bit 26 – COMPE Comparison Event (cleared on read)

Value	Description
0	No comparison event since the last read of ADC_ISR.
1	At least one comparison event (defined in ADC_EMR and ADC_CWR) has occurred since the last read of ADC_ISR.

Bit 25 – GOVRE General Overrun Error (cleared on read)

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	No general overrun error occurred since the last read of ADC_ISR.
1	At least one general overrun error has occurred since the last read of ADC_ISR.

Bit 24 – DRDY Data Ready (automatically set / cleared)

Value	Description
0	No data has been converted since the last read of ADC_LCDR.
1	At least one data has been converted and is available in ADC_LCDR.

Bit 22 – PRDY Touchscreen Pressure Measure Ready (cleared on read)

Value	Description
0	No measure has been performed since the last read of ADC_PRESSR.
1	At least one measure has been performed since the last read of ADC_ISR.

Bit 21 – YRDY Touchscreen YPOS Measure Ready (cleared on read)

Value	Description
0	No measure has been performed since the last read of ADC_YPOSR.
1	At least one measure has been performed since the last read of ADC_ISR.

Bit 20 – XRDY Touchscreen XPOS Measure Ready (cleared on read)

Value	Description
0	No measure has been performed since the last read of ADC_XPOSR.
1	At least one measure has been performed since the last read of ADC_ISR.

Bit 19 – LCCHG Last Channel Change (cleared on read)

Value	Description
0	There is no comparison match (defined in the Last Channel Compare Window register (ADC_LCCWR) since the last read of ADC_ISR.
1	The converted value reported on ADC_CDR7 has changed since the last read of ADC_ISR, according to what is defined in ADC_LCTMR and ADC_LCCWR.

Bits 0, 1, 2, 3, 4, 5, 6, 7 – EOCx End of Conversion x (automatically set / cleared)

Value	Description
0	The corresponding analog channel is disabled, or the conversion is not finished. This flag is cleared when reading the corresponding ADC_CDRx registers.
1	The corresponding analog channel is enabled and conversion is complete.

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.12. ADC Last Channel Trigger Mode Register

Name: ADC_LCTMR
Offset: 0x34
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			CMPMOD[1:0]					DUALTRIG
Access			R/W	R/W				R/W
Reset			0	0				0

Bits 5:4 – CMPMOD[1:0] Last Channel Comparison Mode

Value	Name	Description
0	LOW	Generates the ADC_ISR.LCCHG flag when the converted data is lower than the low threshold of the window.
1	HIGH	Generates the ADC_ISR.LCCHG flag when the converted data is higher than the high threshold of the window.
2	IN	Generates the ADC_ISR.LCCHG flag when the converted data is in the comparison window.
3	OUT	Generates the ADC_ISR.LCCHG flag when the converted data is out of the comparison window.

Bit 0 – DUALTRIG Dual Trigger On

Value	Description
0	All channels are triggered by event defined by ADC_MR.TRGSEL.
1	Last channel (higher index) trigger period is defined by RTC_MR.OUT1.

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.13. ADC Last Channel Compare Window Register

Name: ADC_LCCWR
Offset: 0x38
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
					HIGHTHRES[11:8]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	23	22	21	20	19	18	17	16
	HIGHTHRES[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
					LOWTHRES[11:8]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 27:16 – HIGHTHRES[11:0] High Threshold
High threshold associated to compare settings of ADC_LCTMR.

Bits 11:0 – LOWTHRES[11:0] Low Threshold
Low threshold associated to compare settings of ADC_LCTMR.

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.14. ADC Overrun Status Register

Name: ADC_OVER
Offset: 0x3C
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset

Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 0, 1, 2, 3, 4, 5, 6, 7 – OVREx Overrun Error x

Note: An overrun error does not always mean that the unread data has been replaced by a new valid data. See Enhanced Resolution Mode and Digital Averaging Function for details.

Value	Description
0	No overrun error on the corresponding channel since the last read of ADC_OVER.
1	An overrun error has occurred on the corresponding channel since the last read of ADC_OVER.

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.15. ADC Extended Mode Register

Name: ADC_EMR
Offset: 0x40
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
			ADCMODE[1:0]			SIGNMODE[1:0]		TAG
Access			R/W	R/W		R/W	R/W	R/W
Reset			0	0		0	0	0

Bit	23	22	21	20	19	18	17	16
		TRACKX4	SRCCLK	ASTE		OSR[2:0]		
Access		R/W	R/W	R/W		R/W	R/W	R/W
Reset		0	0	0		0	0	0

Bit	15	14	13	12	11	10	9	8
			CMPFILTER[1:0]				CMPALL	
Access			R/W	R/W			R/W	
Reset			0	0			0	

Bit	7	6	5	4	3	2	1	0
	CMPSEL[3:0]					CMPTYPE	CMPMODE[1:0]	
Access	R/W	R/W	R/W	R/W		R/W	R/W	R/W
Reset	0	0	0	0		0	0	0

Bits 29:28 – ADCMODE[1:0] ADC Running Mode
See Automatic Error Correction for details on ADC Running mode.

Value	Name	Description
0	NORMAL	Normal mode of operation.
1	OFFSET_ERROR	Offset Error mode to measure the offset error. See Table 44.6.
2	GAIN_ERROR_HIGH	Gain Error mode to measure the gain error. See Table 44.6.
3	GAIN_ERROR_LOW	Gain Error mode to measure the gain error. See Table 44.6.

Bits 26:25 – SIGNMODE[1:0] Sign Mode
If conversion results are signed and resolution is below 16 bits, the sign is extended up to the bit 15 (for example, 0xF43 for 12-bit resolution will be read as 0xFF43 and 0x467 will be read as 0x0467). See Conversion Results Format.

Value	Name	Description
0	SE_UNSG_DF_SIGN	Single-Ended channels: Unsigned conversions.Pseudo-differential channels and Differential channels: Signed conversions.
1	SE_SIGN_DF_UNSG	Single-Ended channels: Signed conversions.Pseudo-differential channels and Differential channels: Unsigned conversions.
2	ALL_UNSIGNED	All channels: Unsigned conversions.
3	ALL_SIGNED	All channels: Signed conversions.

Bit 24 – TAG Tag of ADC_LCDR

Value	Description
0	Sets ADC_LCDR.CHNB field to zero.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	Appends the channel number to the conversion result in ADC_LCDR.

Bit 22 – TRACKX4 Tracking Time Extension
See ADC_MR.TRACKTIM description.

Bit 21 – SRCCLK External Clock Selection

Value	Name	Description
0	PERIPH_CLK	The peripheral clock is the source for the ADC prescaler.
1	GCLK	GCLK is the source clock for the ADC prescaler, thus the ADC clock can be independent of the core/peripheral clock.

Bit 20 – ASTE Averaging on Single Trigger Event

Value	Name	Description
0	MULTI_TRIG_AVERAGE	The average requests several trigger events.
1	SINGLE_TRIG_AVERAGE	The average requests only one trigger event.

Bits 18:16 – OSR[2:0] Over Sampling Rate

Value	Name	Description
0	NO_AVERAGE	No averaging. ADC sample rate is maximum.
1	OSR4	1-bit enhanced resolution by averaging. ADC sample rate divided by 4.
2	OSR16	2-bit enhanced resolution by averaging. ADC sample rate divided by 16.
3	OSR64	3-bit enhanced resolution by averaging. ADC sample rate divided by 64.
4	OSR256	4-bit enhanced resolution by averaging. ADC sample rate divided by 256.

Bits 13:12 – CMPFILTER[1:0] Compare Event Filtering
Number of consecutive compare events necessary to raise the flag = CMPFILTER+1
When programmed to 0, the flag rises as soon as an event occurs.
See Comparison Windows when using the filtering option (CMPFILTER > 0).

Bit 9 – CMPALL Compare All Channels

Value	Description
0	Only channel indicated in CMPSEL field is compared.
1	All channels are compared.

Bits 7:4 – CMPSEL[3:0] Comparison Selected Channel
If CMPALL = 0: CMPSEL indicates which channel has to be compared.
If CMPALL = 1: No effect.

Bit 2 – CMPTYPE Comparison Type

Value	Name	Description
0	FLAG_ONLY	Any conversion is performed and comparison function drives the ADC_ISR.COMPE flag.
1	START_CONDITION	Comparison conditions must be met to start the storage of all conversions until the ADC_CR.CMPRST bit is set.

Bits 1:0 – CMPMODE[1:0] Comparison Mode

Value	Name	Description
0	LOW	When the converted data is lower than the low threshold of the window, generates the ADC_ISR.COMPE flag.
1	HIGH	When the converted data is higher than the high threshold of the window, generates the ADC_ISR.COMPE flag.
2	IN	When the converted data is in the comparison window, generates the ADC_ISR.COMPE flag.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
3	OUT	When the converted data is out of the comparison window, generates the ADC_ISR.COMPE flag.

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.16. ADC Compare Window Register

Name: ADC_CWR
Offset: 0x44
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	HIGHTHRES[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16
	HIGHTHRES[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8
	LOWTHRES[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
	LOWTHRES[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:16 – HIGHTHRES[15:0] High Threshold
High threshold associated to compare settings of ADC_EMR.

Bits 15:0 – LOWTHRES[15:0] Low Threshold
Low threshold associated to compare settings of ADC_EMR.

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.17. Channel Configuration Register

Name: ADC_CCR
Offset: 0x4C
Reset: 0
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	DIFF7	DIFF6	DIFF5	DIFF4	DIFF3	DIFF2	DIFF1	DIFF0
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
Access								
Reset								

Bits 16, 17, 18, 19, 20, 21, 22, 23 – DIFFx Differential Inputs for Channel x

Value	Description
0	The corresponding channel is set in Single-Ended mode.
1	The corresponding channel is set in Differential mode.

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.18. ADC Channel Data Register

Name: ADC_CDRx
Offset: 0x50 + x*0x04 [x=0..7]
Reset: 0
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	DATA[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	DATA[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 15:0 – DATA[15:0] Converted Data

The analog-to-digital conversion data is placed into this register at the end of a conversion and remains until a new conversion is completed. ADC_CDRx is only loaded if the corresponding analog channel is enabled.

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.19. ADC Analog Control Register

Name: ADC_ACR
Offset: 0x94
Reset: 0x00001200
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

By default, bits 12 and 13 are set to 1 and 0, respectively, and must not be modified.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
							IBCTL[1:0]	
Access							R/W	R/W
Reset							1	0

Bit	7	6	5	4	3	2	1	0
							PENDETSENS[1:0]	
Access							R/W	R/W
Reset							0	0

Bits 9:8 – IBCTL[1:0] ADC Bias Current Control
Adapts performance versus power consumption. Refer to the “Electrical Characteristics” section for further details.
Note: For sampling frequencies higher than 500 ksps, IBCTL must be written to 1.

Bits 1:0 – PENDETSENS[1:0] Pen Detection Sensitivity
Modifies the pen detection input pull-up resistor value. Refer to the section “Electrical Characteristics” for further details.

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.20. ADC Pseudo-Differential Register

Name: ADC_PDR
Offset: 0xA0
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	PDIFF7	PDIFF6	PDIFF5	PDIFF4	PDIFF3	PDIFF2	PDIFF1	PDIFF0
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 0, 1, 2, 3, 4, 5, 6, 7 – PDIFFx Pseudo-Differential Inputs for Channel x

Value	Description
0	The channel is configured as defined by the ADC_CCR.DIFFx bit.
1	The channel is configured in Pseudo-Differential mode.

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.21. ADC Touchscreen Mode Register

Name: ADC_TSMR
Offset: 0xB0
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	PENDBC[3:0]							PENDET
Access	R/W	R/W	R/W	R/W				R/W
Reset	0	0	0	0				0

Bit	23	22	21	20	19	18	17	16
		NOTSDMA			TSSCTIM[3:0]			
Access		R/W			R/W	R/W	R/W	R/W
Reset		0			0	0	0	0

Bit	15	14	13	12	11	10	9	8
					TSFREQ[3:0]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
			TSAV[1:0]				TSMODE[1:0]	
Access			R/W	R/W			R/W	R/W
Reset			0	0			0	0

Bits 31:28 – PENDBC[3:0] Pen Detect Debouncing Period
Debouncing period = 2^{PENDBC} ADCCLK periods.

Bit 24 – PENDET Pen Contact Detection Enable
When PENDET = 1, XPOS, YPOS, Z1, Z2 values of ADC_XPOSR, ADC_YPOSR, ADC_PRESSR are automatically cleared when ADC_ISR.PENS = 0.

Value	Description
0	Pen contact detection disabled.
1	Pen contact detection enabled.

Bit 22 – NOTSDMA No TouchScreen DMA

Value	Description
0	XPOS, YPOS, Z1, Z2 are transmitted in ADC_LCDR.
1	XPOS, YPOS, Z1, Z2 are never transmitted in ADC_LCDR, therefore the buffer does not contains touchscreen values.

Bits 19:16 – TSSCTIM[3:0] Touchscreen Switches Closure Time
Defines closure time of analog switches necessary to establish the measurement conditions.
The closure time is:
Switch Closure Time = (TSSCTIM × 4) ADCCLK periods.

Bits 11:8 – TSFREQ[3:0] Touchscreen Frequency
Defines the touchscreen frequency compared to the trigger frequency.

© 2026 Microchip Technology Inc. and its subsidiaries

TSFREQ must be greater or equal to TSAV.
The touchscreen frequency is:
Touchscreen Frequency = Trigger Frequency / 2^{TSFREQ}

Bits 5:4 – TSAV[1:0] Touchscreen Average

Value	Name	Description
0	NO_FILTER	No filtering. Only one ADC conversion per measure.
1	AVG2CONV	Averages 2 ADC conversions.
2	AVG4CONV	Averages 4 ADC conversions.
3	AVG8CONV	Averages 8 ADC conversions.

Bits 1:0 – TSMODE[1:0] Touchscreen Mode
When TSMOD equals 01 or 10 (i.e., 4-wire mode), channels 0, 1, 2 and 3 must not be used for classic ADC conversions. When TSMOD equals 11 (i.e., 5-wire mode), channels 0, 1, 2, 3, and 4 must not be used.

Value	Name	Description
0	NONE	No touchscreen.
1	4_WIRE_NO_PM	4-wire touchscreen without pressure measurement.
2	4_WIRE	4-wire touchscreen with pressure measurement.
3	5_WIRE	5-wire touchscreen.

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.22. ADC Touchscreen X Position Register

Name: ADC_XPOSR
Offset: 0xB4
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
					XSCALE[11:8]			
Access					R	R	R	R
Reset					0	0	0	0

Bit	23	22	21	20	19	18	17	16
	XSCALE[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
					XPOS[11:8]			
Access					R	R	R	R
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
	XPOS[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 27:16 – XSCALE[11:0] Scale of XPOS
Indicates the max value that XPOS can reach. This value should be close to 2^{12}.

Bits 11:0 – XPOS[11:0] X Position
The position measured is stored here. If XPOS = 0 or XPOS = XSIZE, the pen is on the border. When pen detection is enabled (ADC_TSMR.PENDET set to '1'), XPOS is tied to 0 while there is no detection of contact on the touchscreen (i.e., when the ADC_ISR.PENS bit is cleared).

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.23. ADC Touchscreen Y Position Register

Name: ADC_YPOSR
Offset: 0xB8
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
					YSCALE[11:8]			
Access					R	R	R	R
Reset					0	0	0	0

Bit	23	22	21	20	19	18	17	16
	YSCALE[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
					YPOS[11:8]			
Access					R	R	R	R
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
	YPOS[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 27:16 – YSCALE[11:0] Scale of YPOS
Indicates the max value that YPOS can reach. This value should be close to 2^{12}.

Bits 11:0 – YPOS[11:0] Y Position
The position measured is stored here. If YPOS = 0 or YPOS = YSIZE, the pen is on the border. When pen detection is enabled (ADC_TSMR.PENDET set to '1'), YPOS is tied to 0 while there is no detection of contact on the touchscreen (i.e., when the ADC_ISR.PENS bit is cleared).

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.24. ADC Touchscreen Pressure Register

Name: ADC_PRESSR
Offset: 0xBC
Reset: 0x00000000
Property: Read-only

Note: These values are unavailable if ADC_TSMR.TSMODE is not set to 2.

Bit	31	30	29	28	27	26	25	24
					Z2[11:8]			
Access					R	R	R	R
Reset					0	0	0	0

Bit	23	22	21	20	19	18	17	16
	Z2[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
					Z1[11:8]			
Access					R	R	R	R
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
	Z1[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 27:16 – Z2[11:0] Data of Z2 Measurement
Data Z2 necessary to calculate pen pressure.
When pen detection is enabled (ADC_TSMR.PENDET set to ‘1’), Z2 is tied to 0 while there is no detection of contact on the touchscreen (i.e., when the ADC_ISR.PENS bit is cleared).

Bits 11:0 – Z1[11:0] Data of Z1 Measurement
Data Z1 necessary to calculate pen pressure.
When pen detection is enabled (ADC_TSMR.PENDET set to ‘1’), Z1 is tied to 0 while there is no detection of contact on the touchscreen (i.e., when the ADC_ISR.PENS bit is cleared).

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.25. ADC Trigger Register

Name: ADC_TRGR
Offset: 0xC0
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	TRGPER[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	23	22	21	20	19	18	17	16
	TRGPER[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8
Access								
Reset								
Bit	7	6	5	4	3	2	1	0
						TRGMOD[2:0]		
Access						R/W	R/W	R/W
Reset						0	0	0

Bits 31:16 – TRGPER[15:0] Trigger Period
Effective only if TRGMOD defines a periodic trigger.
Defines the periodic trigger period, with the following equation:
Trigger Period = (TRGPER + 1) / ADCCLK
The minimum time between two consecutive trigger events must be strictly greater than the duration time of the longest conversion sequence depending on the configuration of registers ADC_MR, ADC_CHSR, ADC_SEQR1, ADC_TSMR.
When TRGMOD is set to pen detect trigger (i.e., 100) and averaging is used (i.e., field TSAV ≠ 0 in ADC_TSMR) only one measure is performed. Thus, XRDY, YRDY, PRDY, DRDY will not rise on pen contact trigger. To achieve measurement, several triggers must be provided either by software or by setting the TRGMOD on continuous trigger (i.e., 110) until flags rise.

Bits 2:0 – TRGMOD[2:0] Trigger Mode

Value	Name	Description
0	NO_TRIGGER	No hardware trigger enabled, only software trigger can start conversions
1	EXT_TRIG_RISE	Rising edge of the selected hardware trigger event, defined in ADC_MR.TRGSEL
2	EXT_TRIG_FALL	Falling edge of the selected hardware trigger event
3	EXT_TRIG_ANY	Any edge of the selected hardware trigger event
4	PEN_TRIG	Pen Detect Trigger (shall be selected only if PENDET is set and TSMODE > 0)
5	PERIOD_TRIG	ADC internal hardware periodic trigger (see field TRGPER)
6	CONTINUOUS	Continuous mode

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.26. ADC Correction Values Register

Name: ADC_CVR
Offset: 0xD4
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	GAINCORR[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	GAINCORR[7:0]

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:16 – GAINCORR[15:0] Gain Correction
Gain correction to apply on converted data. Only bits 0 to 15 are relevant (other bits are ignored and read as 0).

Bits 15:0 – OFFSETCORR[15:0] Offset Correction
Offset correction to apply on converted data. The offset is signed (2's complement), only bits 0 to 11 are relevant (other bits are ignored and read as 0).

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.27. ADC Channel Error Correction Register

Name: ADC_CECR
Offset: 0xD8
Reset: 0x00000000
Property: Read/Write

This register can only be written if the WPEN bit is cleared in the ADC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Access	W	W	W	W	W	W	W	W
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
						WPCTEN	WPITEN	WPEN
Access						R/W	R/W	R/W
Reset						0	0	0

Bits 31:8 – WPKEY[23:0] Write Protection Key

Value	Name	Description
0x414443	PASSWD	Writing any other value in this field aborts the write operation of the WPEN bit. Always reads as 0

Bit 2 – WPCTEN Write Protection Control Enable
See Register Write Protection for the list of registers that can be protected.

Value	Description
0	Disables the write protection on control registers if WPKEY corresponds to 0x414443 (“ADC” in ASCII).
1	Enables the write protection on control registers if WPKEY corresponds to 0x414443 (“ADC” in ASCII).

Bit 1 – WPITEN Write Protection Interrupt Enable
See Register Write Protection for the list of registers that can be protected.

Value	Description
0	Disables the write protection on interrupt registers if WPKEY corresponds to 0x414443 (“ADC” in ASCII).
1	Enables the write protection on interrupt registers if WPKEY corresponds to 0x414443 (“ADC” in ASCII).

Bit 0 – WPEN Write Protection Enable
See Register Write Protection for the list of write-protected registers.

Value	Description
0	Disables the write protection if WPKEY value corresponds to 0x414443 (“ADC” in ASCII).
1	Enables the write protection if WPKEY value corresponds to 0x414443 (“ADC” in ASCII).

© 2026 Microchip Technology Inc. and its subsidiaries

44.7.30. ADC Write Protection Status Register

Name: ADC_WPSR
Offset: 0xE8
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	WPVSRC[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
								WPVS
Access								R
Reset								0

Bits 23:8 – WPVSRC[15:0] Write Protection Violation Source
When WPVS = 1, WPVSRC indicates the register address offset at which a write access has been attempted.

Bit 0 – WPVS Write Protection Violation Status

Value	Description
0	No write protection violation has occurred since the last read of ADC_WPSR.
1	A write protection violation has occurred since the last read of ADC_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSRC.

Image Subsystem

45. Overview

45.1. Block Diagram

Figure 45.1. Image Subsystem Block Diagram

45.2. Components

The image subsystem is composed of two sections: Image and Display, made up of MIPI and RGB parallel interfaces. Their components are:

- Image capture:
  - Image Sensor Controller (ISC)
  - CSI-2 Demultiplexer Controller (CSI2DC)
  - Camera Sensor Host Interface (CSI2)
  - Physical interface to connect CSI-2 camera sensors (D-PHY)
- Display:
  - LCD Controller with parallel interface (LCDC)
  - Display serial interface with MIPIPLL (DSI)
  - LVDS Controller with LVDSPLL (LVDSC)
  - 2D Graphical Engine (GFX2D)

45.3. Product Dependencies

45.3.1. Clocks

In addition to MCK fed by PLLA:

© 2026 Microchip Technology Inc. and its subsidiaries

- CSI2 has a GCLK input.
- DSI embeds a PLL, MIPIPLL, configurable using the DSI interface.
- LVDSC embeds a PLL controlled in the Power Management Controller (PMC).

45.3.2. Interrupts

Refer to the table Peripheral Identifiers.

45.3.3. Reset

Image peripherals are connected to the processor and peripherals reset line.

45.3.4. I/Os

- MIPI I/Os are high-speed I/Os powered by VDDMIPI/GND.
- ISC I/Os are multiplexed with other peripherals and powered by VDDLVDS or VDDIOP1.
- LVDS I/Os are multiplexed with other peripherals and powered by VDDLVDS.

Note: When the LVDS PHY is used, VDDLVDS must be connected to VDDOUT25.

45.3.5. Power Saving

To save power consumption, the sensor can stop the image stream. In this case, proceed as follows to enter the image subsystem in Low-power mode:

1. Disable capture in ISC:
   - ISC_CTRLDIS.DISABLE = 1 (to end capture at next vertical synchronization detection)
   - Check ISC_CTRLSR.CAPTURE = 0
2. Power down D-PHY:
   - CSI –> CSI2_RESETN = 0
   - CSI –> CSI2_PHY_SHUTDOWNZ = 0
   - CSI –> CSI2_DPHY_RSTZ = 0
3. Reset CSI2DC software:
   - CSI2DC –> CSI2DC_GCTLR = 1

The image subsystem is now in Low-power mode. Proceed as follows to restart the capture:

1. Enable capture in ISC:
   - With color profile update:
     - Write all required configuration registers.
     - ISC_CTRLEN = 0x3 (CAPTURE =1 and UPPRO =1)
   - Without color profile update:
     - ISC_CTRLDIS.CAPTURE = 1
2. Release CSI2DC software reset:
   - CSI2DC –> CSI2DC_GCTLR = 0
3. Enable image pipe:
   - CSI2DC –> CSI2DC_VPER = 1
   - CSI2DC –> CSI2DC_DPER = 1
   - CSI2DC –> CSI2DC_PUR = 0x3
4. Bring D-PHY out of power down:
   - CSI –> CSI2_PHY_SHUTDOWNZ = 1
   - CSI –> CSI2_DPHY_RSTZ = 1

© 2026 Microchip Technology Inc. and its subsidiaries

- CSI –> CSI2_RESETN = 1
- Wait for LP-11 on the clock lane and activate data lanes by probing the CSI2_PHY_STOPSTATE register.

The image datapath can now start streaming frames.

45.4. LVDS I/O Configuration

45.4.1. Pre-Emphasis

A pre-emphasis booster is a symmetrical switch cap circuit whose ideal gain is determined by the ratio of charges injected/subtracted to/from output nodes versus the reference charges stored in the output load.

When operated, this circuit provides a faster rise/fall transition time to help improve eye diagram aperture – without affecting the DC operating point in the output load.

Capacitors are programmable via the 3-bit trimming field in the LVDSC_ACR register, independently for each data and clock lane.

45.4.2. Common and Bias

The LVDS common has a 5-bit trimmable current source used to bias analog lanes and adjust the LVDS DC output signal amplitude. This is programmed using the LVDSC_ACR register, with the field DCBIAS.

45.5. Special Functions in SFR

Select the MIPI direction (TX or RX) using the SFR_ISS_CFG.MODE bit.

Program 0 for CSI2, or 1 for DSI.

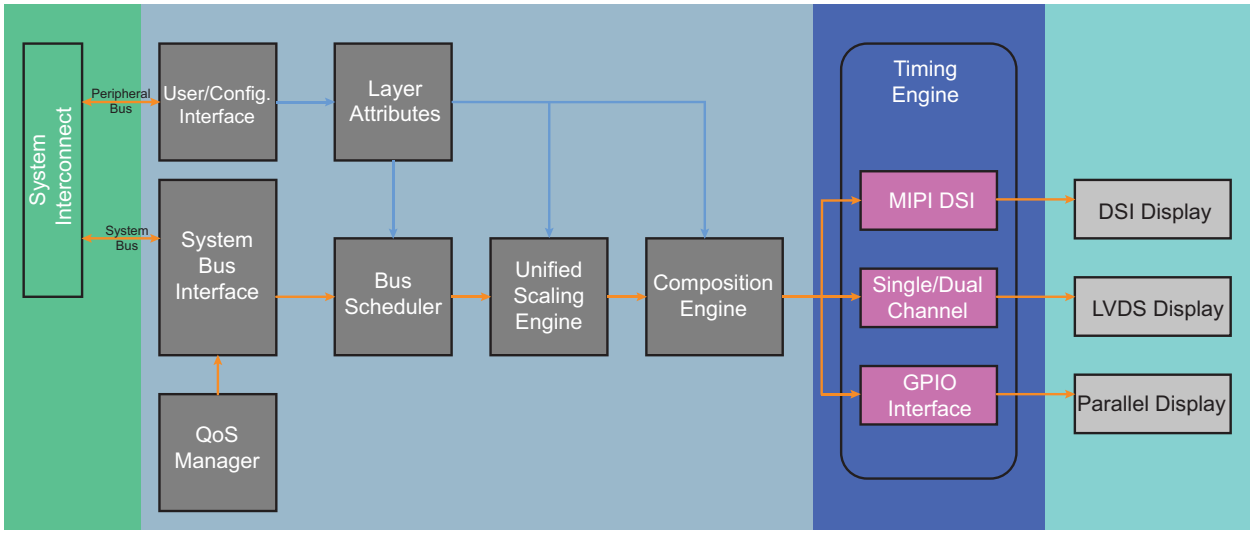
© 2026 Microchip Technology Inc. and its subsidiaries

46. LCD Controller (LCDC)

46.1. Description

The LCD Controller (LCDC) consists of logic for transferring LCD image data from an external display buffer to a TFT LCD panel. The LCDC has one display input buffer per layer that fetches pixels through the single bus host interface and a look-up table to allow palletized display configurations. The LCDC is programmable on a per layer basis, and supports different LCD resolutions, window sizes, image formats and pixel depths.

The LCDC is connected to the system bus as a host for reading pixel data. It also integrates a peripheral bus interface to configure its registers.



46.2. Embedded Characteristics

- Up to 32-bit Host Interface
- Supports Single Scan Active TFT Display
- Supports Parallel RGB, MIPI DSI and Single Channel LVDS Interfaces
- Supports 12-, 16-, 18- and 24-bit Output Mode
- Supports Spatial Dithering for 12-, 16-, and 18-bit Output Mode
- Asynchronous Output Mode Supported
- 1, 2, 4, 8 bits per Pixel (Palletized)
- 12, 16, 18, 19, 24, 25 and 32 bits per Pixel (Non-palletized)
- Supports One Base Layer (Background)
- Supports Overlay 1 Layer
- Supports Overlay 2 Layer
- Supports High-End Overlay (HEO) Layer
- High-End Overlay Supports 4:2:0 Planar Mode and Semiplanar Mode
- High-End Overlay Supports 4:2:2 Planar Mode, Semiplanar Mode and Packed
- Little Endian Memory Organization
- Programmable Timing Engine, with Integer Clock Divider
- Programmable Polarity for Data, Line Synchro and Frame Synchro
- Up to 1024x768 (XGA) with Overlay (Application-Dependent); Still Image up to 1280x720 (720p)
- Color Look-up Table (CLUT) with up to 256 Entries and Predefined 8-bit Alpha
- Gamma Correction through Color Look-Up Table (CLUT)
- Programmable Negative and Positive Row Striding for all Layers
- Horizontal and Vertical Rescaling Unit with Edge Interpolation and Independent Non-Integer Ratio, up to 1280x720 (720p)
- Bandwidth and Power Optimization with Hidden Section of Base Layer
- Integrates Fully Programmable Color Space Conversion
- Blender Function Supports Arbitrary 8-bit Alpha Value and Chroma Keying

LVDS_A2M		
LVDS_A3P	Differential LVDS data 3 line transceiver output	Output
LVDS_A3M		

46.5. Product Dependencies

46.5.1. I/O Lines

The pins used for interfacing the LCDC may be multiplexed with PIO lines. The programmer must first program the PIO Controller to assign the pins to their peripheral function. If I/O lines of the LCDC are not used by the application, they can be used for other purposes by the PIO Controller.

46.5.2. Power Management

The LCDC is not continuously clocked. Before using it, the user must first enable the LCDC peripheral and generic (GCLK) clocks in the Power Management Controller.

If the LVDS interface is used, once the LVDS PLL is enabled the pixel clock is used as the clock for LCDC and the GCLK is no longer needed.

46.5.3. Interrupt Sources

The LCDC interrupt line is connected to one of the internal sources of the interrupt controller. Using the LCDC interrupt requires prior programming of the interrupt controller (see Interrupt Software Operations).

46.6. Functional Description

The LCDC module integrates the following digital blocks:

- DMA Engine—this block performs data prefetch and requests access to the system bus interface.
- Input Layer FIFO—stores the stream of pixels
- Color Look-up Table (CLUT)—these 256 RAM-based look-up table entries are selected when the color depth is set to 1, 2, 4 or 8 bpp.
- Color Space Conversion (CSC)—changes the color space from YCbCr to RGB
- Two Dimension Scaler (2DSC)—resizes the image
- Global Alpha Blender (GAB)—performs programmable 256-level alpha blending
- Output FIFO—stores the blended pixel prior to displaying
- LCD Timing Engine—provides a fully programmable HSYNC-VSYNC interface

The DMA controller reads the image through the system bus host interface. The LCDC engine formats the display data, then the GAB performs alpha blending if required, and writes the final pixel into the output FIFO. The programmable timing engine drives a valid pixel onto the LCD output interface.

46.6.1. Timing Engine Configuration

Before writing in the Configuration registers, LCDC_LCDCFGx, of the timing engine, the bit SIPSTS in the Status register (LCDC_LCDSR) must be cleared.

46.6.1.1. Pixel Clock Period Configuration

The pixel clock (LCDC_PCK) generated by the timing engine is the source clock divided by the field CLKDIV in the Configuration register 0 (LCDC_LCDCFG0). The source clock is the GCLK clock.

The pixel clock period formula is:

© 2026 Microchip Technology Inc. and its subsidiaries

$$\text{LCDC_PCK} = \frac{\text{source clock}}{\text{CLKDIV}+2}$$

To obtain LCDC_PCK = source clock, the clock divider can be disabled by configuring LCDC_LCDCFG0.CLKBYP.

The pixel clock polarity can be programmed in LCDC_LCDCFG0.CLKPOL.

46.6.1.2.Horizontal and Vertical Synchronization Configuration

The following fields are used to configure the timing engine:

- LCDC_LCDCFG1.HSPW
- LCDC_LCDCFG1.VSPW
- LCDC_LCDCFG2.VFPW
- LCDC_LCDCFG2.VBPW
- LCDC_LCDCFG3.HFPW
- LCDC_LCDCFG3.HBPW
- LCDC_LCDCFG4.PPL
- LCDC_LCDCFG4.RPF

The polarity of output signals is also programmable.

46.6.1.3.Timing Engine Power-Up Software Operation

The following sequence enables the display:

1. Configure the LCD timing parameters, signal polarity and clock period in LCDC_LCDCFGx.
2. Enable the pixel clock by writing a one to CLKEN in the Enable register (LCDC_LCDEN).
3. Poll CLKSTS in the Status register (LCDC_LCDSR) to check that the clock is running.
4. Enable horizontal and vertical synchronization by writing a one to LCDC_LCDEN.SYNCEN.
5. Poll LCDC_LCDSR.LCDSTS to check that the synchronization is up.
6. Enable the display power signal by writing a one to LCDC_LCDEN.DISPEN.
7. Poll LCDC_LCDSR.DISPSTS to check that the power signal is activated.
8. If the MIPI output interface is selected and if the display supports the shutdown command, turn on the display by writing a one to LCDC_LCDEN.SDEN.
9. If the MIPI output interface is selected and if the display supports the shutdown command, poll LCDC_LCDSR.SDSTS to check that the shutdown signal output is zero.

LCDC_LCDCFG5.GUARDTIME is used to configure the number of frames before the assertion of the signal LCDC_DISP.

46.6.1.4.Timing Engine Power-Down Software Operation

The following sequence disables the display:

1. If the MIPI output interface is selected and if the display supports the shutdown command, turn off the display by writing a one to LCDC_LCDDIS.SDDIS.
2. If the MIPI output interface is selected and if the display supports the shutdown command, poll LCDC_LCDSR.SDSTS to check that the shutdown signal output is one.
3. Disable LCDC_DISP by writing DISPDIS in the Disable register (LCDC_LCDDIS).
4. Poll LCDC_LCDSR.DISPSTS to verify that LCDC_DISP is no longer enabled.
5. Disable the HSYNC and VSYNC signals by writing a one to LCDC_LCDDIS.SYNCDIS.
6. Poll LCDC_LCDSR.LCDSTS to check that the synchronization is off.
7. Disable the pixel clock by writing a one to LCDC_LCDDIS.CLKDIS.

© 2026 Microchip Technology Inc. and its subsidiaries

46.6.2. Interrupt Software Operations

The LCDC includes two interrupt levels. Specific modules or layers have their own low-level interrupt vector (Base Layer, Overlay 1, Overlay 2, High-End Overlay, Write Protection). Each of their sources can be controlled by an Interrupt Enable register, Interrupt Disable register, and Interrupt Mask register, and can be monitored by an Interrupt Status register. The table below shows the different layers and the registers dedicated to interrupts.

Table 46.2. Low-level Interrupt Register List

Module	Interrupt Enable Register	Interrupt Disable Register	Interrupt Mask Register	Interrupt Status Register
Base Layer	LCDC_BASEIER	LCDC_BASEIDR	LCDC_BASEIMR	LCDC_BASEISR
Overlay 1	LCDC_OVR1IER	LCDC_OVR1IDR	LCDC_OVR1IMR	LCDC_OVR1ISR
Overlay 2	LCDC_OVR2IER	LCDC_OVR2IDR	LCDC_OVR2IMR	LCDC_OVR2ISR
High-End Overlay	LCDC_HEOIER	LCDC_HEOIDR	LCDC_HEOIMR	LCDC_HEOISR
Write Protection	–	–	–	LCDC_WPSR

Each low-level interrupt is summarized in a single source for the main-level Interrupt vector which is controlled by LCDC_LCDIER, LCDC_LCDIDR and LCDC_LCDIMR, and can be monitored with LCDC_LCDISR. It can be driven by the following sources:

- Start of frame event
- LCD disable terminated
- Display power-up/power-down terminated
- Configurable active row number event
- Output FIFO underflow
- Base Layer interrupt
- Overlay 1 interrupt
- Overlay 2 interrupt
- High-End Overlay interrupt
- Write Protection interrupt

If any low-level interrupt is triggered, then the main-level interrupt is triggered as well if the source related to the corresponding module is enabled in LCDC_LCDIER. If any main-level interrupt is triggered, then the LCDC interrupt line is raised.

The sequence to clear a low-level interrupt is the following:

1. Read LCDC_LCDISR and identify the source module.
2. Read the corresponding low-level Interrupt Status register.
3. In case of persistent error, take action to stop the error source.
4. Re-read the corresponding low-level Interrupt Status register to clear it.

Once a low-level interrupt is cleared, the corresponding main-level source is automatically cleared.

46.6.3. DMA Software Operations

46.6.3.1. Enabling DMA Channels

Follow the steps below to enable DMA channels:

1. Check that all fields are cleared in the Attribute Status register (LCDC_ATTRS).
2. Write the Configuration registers of each layer.
3. Set the ENABLE field in the Enable register of each layer (LCDC_xxxEN) .

© 2026 Microchip Technology Inc. and its subsidiaries

4. Write a one to the Update Attribute field for each layer and, if CLUT mode is used and if the CLUT content is fetched by the DMA, write a one to the Update Color LUT field for each layer in the Attribute Enable register (LCDC_ATTRE).

46.6.3.2. Disabling DMA Channels

Follow the steps below to disable DMA channels:

1. Check that all fields are cleared in LCDC_ATTRS.
2. Clear the ENABLE field in the Enable registers of each layer (LCDC_xxxEN).
3. Write a one to the Update Attribute field for each layer in LCDC_ATTRE.

46.6.3.3. Modifying the Layer Attributes

Follow the steps below to modify layer attributes:

1. Check that all fields are cleared in LCDC_ATTRS.
2. Write the desired attribute fields in the Configuration registers, Frame Buffer registers and Enable registers of each layer.
3. Write a one to the Update Attribute field for each layer and, if required, write a one to the Update Color LUT field for each layer in LCDC_ATTRE.

46.6.3.4. DMA Interrupt Generation

The DMA Controller operation sets the following interrupt flags in the layer Interrupt Status registers:

- END—indicates that the current frame DMA transfer is completed.
- ERROR—indicates that a bus transfer error has been detected.
- OVF—indicates that a DMA transfer is still pending at the end of frame.

46.6.3.5. Frame Buffer DMA Address Alignment Requirements

When programming the Frame Buffer registers of each layer (LCDC_xxxFBA), the following requirements must be met:

Table 46.3. Frame Buffer DMA Address Alignment when CLUT Mode is Selected

CLUT Mode	DMA Address Alignment
1 bpp	8 bits
2 bpp	8 bits
4 bpp	8 bits
8 bpp	8 bits

Table 46.4. Frame Buffer DMA Address Alignment when RGB Mode is Selected

RGB Mode	DMA Address Alignment
12 bpp RGB 444	16 bits
16 bpp ARGB 4444	16 bits
16 bpp RGBA 4444	16 bits
16 bpp RGB 565	16 bits
16 bpp ARGB 1555	16 bits
18 bpp RGB 666	32 bits
18 bpp RGB 666 PACKED	8 bits
19 bpp ARGB 1666	32 bits
19 bpp ARGB 1666 PACKED	8 bits
24 bpp RGB 888	32 bits
24 bpp RGB 888 PACKED	8 bits

Table 46.4. Frame Buffer DMA Address Alignment when RGB Mode is Selected (continued)

RGB Mode	DMA Address Alignment
25 bpp ARGB 1888	32 bits
32 bpp ARGB 8888	32 bits
32 bpp RGBA 8888	32 bits

Table 46.5. Frame Buffer DMA Address Alignment when YCbCr Mode is Selected

YCbCr Mode	DMA Address Alignment
32 bpp AYCbCr	32 bits
16 bpp YCbCr 4:2:2	32 bits
16 bpp semiplanar YCbCr 4:2:2	Y 8 bits
	CbCr 16 bits
16 bpp planar YCbCr 4:2:2	Y 8 bits
	Cb 8 bits
	Cr 8 bits
12 bpp semiplanar YCbCr 4:2:0	Y 8 bits
	CbCr 16 bits
12 bpp planar YCbCr 4:2:0	Y 8 bits
	Cb 8 bits
	Cr 8 bits

46.6.4. Layer Software Configuration

46.6.4.1. System Bus Access Attribute

This attribute is defined to improve bandwidth of the layer.

- BLEN field—Defines the maximum burst length of the DMA channel.

46.6.4.2. Color Attributes

- CLUTMODE field—Selects the CLUT mode.
- RGBMODE field—Selects the RGB mode.
- GAM field—Activates gamma correction when true RGB color is activated.
- YCCMODE field—Selects the Luma Chroma mode.

46.6.4.3. Color Look-Up Table Configuration

For each layer, the LCDC includes four 256-entry color look-up tables (CLUT) that can be used either for indexed color formats (up to 8bpp) or for gamma correction. One CLUT is dedicated to each pixel component (A, R, G and B).

When indexed color format is used, the frame buffer contains the CLUT read address used to recall the corresponding real ARGB pixel value previously stored.

For more details about gamma correction, see Gamma Correction.

There are two ways to load CLUT values:

1. through the User Interface
2. by DMA access

From the User Interface, the CLUT can be accessed directly at the corresponding address space, but only when the targeted layer CLUT and gamma correction are disabled (see LCDC_BASECLA, LCDC_OVR1CLA, LCDC_OVR2CLA, LCDC_HEOCLA). The CLUT content can also be fetched by the DMA at the next start of frame, before fetching the frame buffer. The following sequence is used to update the CLUT:

© 2026 Microchip Technology Inc. and its subsidiaries

1. Write the CLUT content(s) in memory.
2. Configure the CLA field in the Color Look-Up Table Address registers of each layer (LCDC_xxxCLA).
3. Check that all fields in LCDC_ATTRS are cleared.
4. Write a one to the Update Color LUT field for each layer in LCDC_ATTRE.

46.6.4.4. Window Position, Size, Scaling and Striding Attributes

- XPOS and YPOS fields—Defines the position of the layer window.
- XSIZE and YSIZE fields—Defines the size of the displayed window.
- XMEMSIZE and YMEMSIZE fields—Defines the size of the image frame buffer.
- XSTRIDE —Defines the line striding.
- PSTRIDE —Defines the pixel striding.
- VXSYFACTOR and VXSCFACTOR fields—Defines the scaling ratio for the vertical scaler.
- HXSYFACTOR and HXSCFACTOR fields—Defines the scaling ratio for the horizontal scaler.

The position and size attributes are programmed to keep the window within the display area.

When CLUT mode is enabled, the restrictions detailed in the following table apply on the horizontal, vertical window sizes and discard attributes (Discard Area Horizontal Position, Discard Area Vertical Position, Discard Area Horizontal Size, Discard Area Vertical Size).

Table 46.6. CLUT Mode and Window Size/Discard Attributes

CLUT Mode	X-Y Size/Discard Attributes Requirement
1 bpp	Multiple of 8 pixels
2 bpp	Multiple of 4 pixels
4 bpp	Multiple of 2 pixels
8 bpp	Free size

Pixel striding is disabled when CLUT mode is enabled.

Depending on the input mode, the restrictions detailed in the following table apply on the window size.

Table 46.7. Window Size

Mode	X-Y Requirement, Scaling Turned Off	X-Y Requirement, Scaling Turned On	XMEM_SIZE-YMEM_SIZE Requirement, Scaling Turned On
ARGB/CLUT	Free size	XSIZE ≥ 3 pixels YSIZE ≥ 3 pixels	XMEM_SIZE ≥ 3 pixels YMEM_SIZE ≥ 3 pixels
AYCbCr 4:4:4	Free size	XSIZE ≥ 3 pixels YSIZE ≥ 3 pixels	XMEM_SIZE ≥ 3 pixels YMEM_SIZE ≥ 3 pixels
YCbCr 4:2:2 packed	XSIZE ≥ 6 pixels Free YSIZE	XSIZE ≥ 6 pixels YSIZE ≥ 3 pixels	XMEM_SIZE ≥ 6 pixels, even YMEM_SIZE ≥ 3 pixels
YCbCr 4:2:2 semiplanar	XSIZE ≥ 6 pixels Free YSIZE	XSIZE ≥ 6 pixels YSIZE ≥ 3 pixels	XMEM_SIZE ≥ 6 pixels YMEM_SIZE ≥ 3 pixels
YCbCr 4:2:2 planar	XSIZE ≥ 6 pixels Free YSIZE	XSIZE ≥ 6 pixels YSIZE ≥ 3 pixels	XMEM_SIZE ≥ 6 pixels YMEM_SIZE ≥ 3 pixels
YCbCr 4:2:0 semiplanar	XSIZE ≥ 6 pixels YSIZE ≥ 6 pixels	XSIZE ≥ 6 pixels YSIZE ≥ 6 pixels	XMEM_SIZE ≥ 6 pixels YMEM_SIZE ≥ 6 pixels
YCbCr 4:2:0 planar	XSIZE ≥ 6 pixels YSIZE ≥ 6 pixels	XSIZE ≥ 6 pixels YSIZE ≥ 6 pixels	XMEM_SIZE ≥ 6 pixels YMEM_SIZE ≥ 6 pixels

© 2026 Microchip Technology Inc. and its subsidiaries

46.6.4.5.Overlay Blender Attributes

When two or more video layers are used, alpha blending is performed to define the final image displayed. Each window has its own blending attributes.

- CRKEY bit—Enables the chroma keying and match logic
- DSTKEY bit—When written to one, destination keying is enabled
- SFACTC—Source factor for the color channel blending equation
- SFACTA—Source factor for the Alpha channel blending equation
- DFACTC—Destination factor for the color channel blending equation
- DFACTA—Destination factor
- A0 field—Defines the source window alpha value 0
- A1 field—Defines the source window alpha value 1

46.6.4.6.Layer Attributes Update Operation

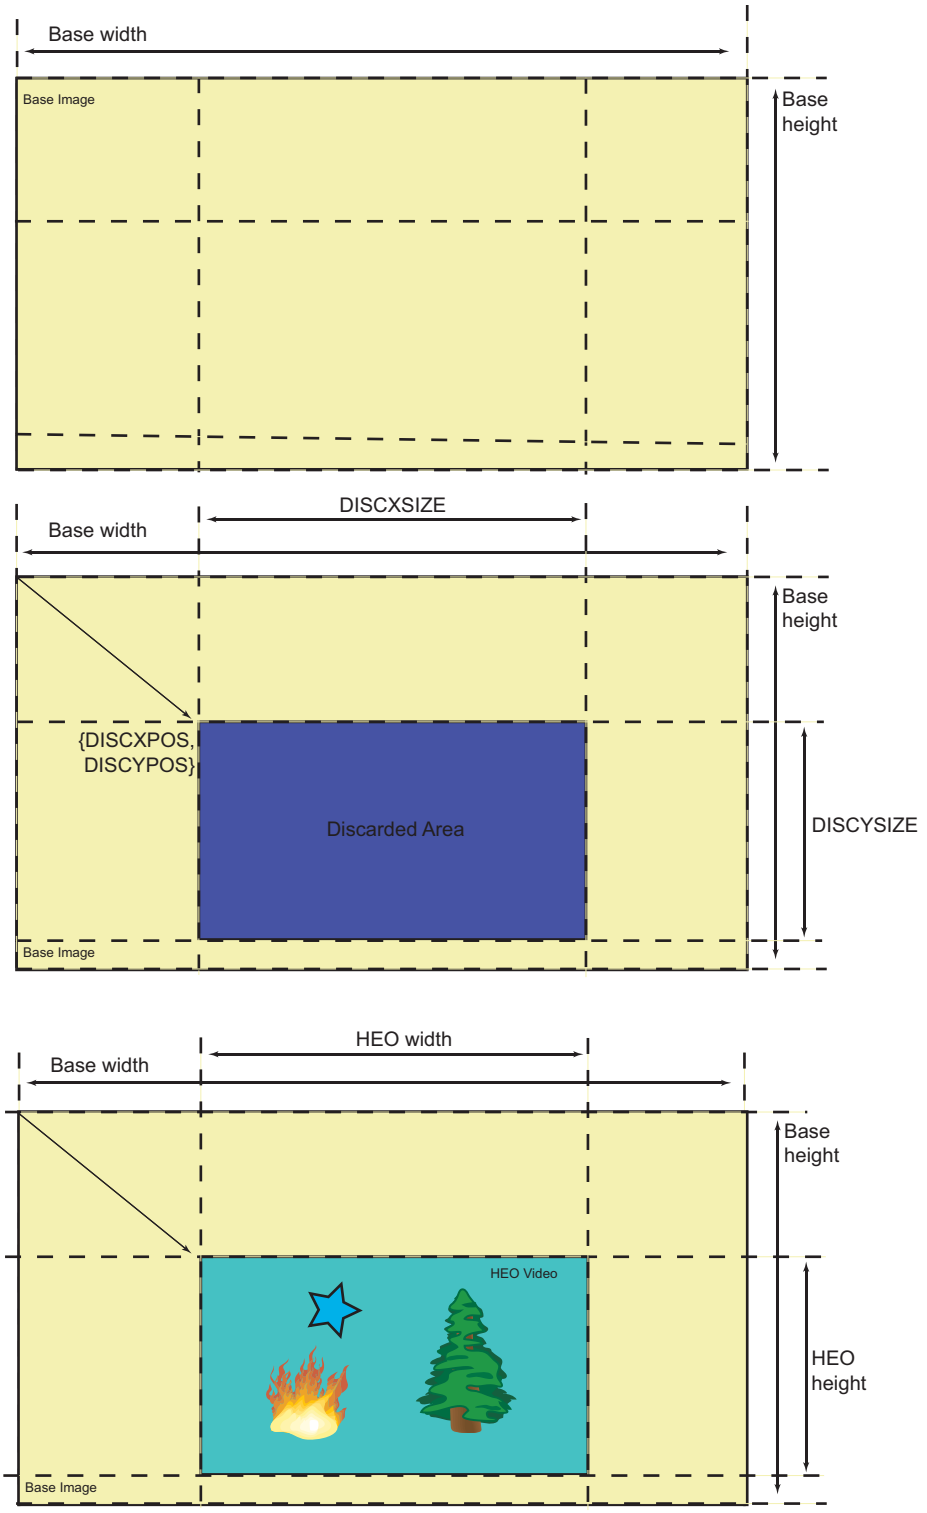
A set of attribute configuration registers (LCDC_xxxCFGx, LCDC_xxxFBA and LCDC_xxxEN, where xxx indicates the layer) is dedicated to each layer and defines attributes specific to that layer. These registers can be updated by using the following procedure:

1. Check that all fields in LCDC_ATTRS are cleared.
2. Write the attribute configuration registers of each layer.
3. Write a one to the Update Attribute field for each layer in LCDC_ATTRE.

46.6.4.7.Bandwidth and Power Optimization with Hidden Section of Base Layer

When the base layer is combined with at least one active overlay (100% opacity overlay), by default, the whole base layer frame is retrieved from the memory though it is not visible.

To optimize the system bandwidth, the LCDC can be configured to prevent the unuseful data from being fetched from system memory.



The following registers are used to disable an invisible area of the base layer:

- LCDC_BASECFG5:
  - field DISCXPOS (Discard Area Horizontal Position)
  - field DISCYPOS (Discard Area Vertical Position)
- LCDC_BASECFG6:
  - field DISCXSIZE (Discard Area Horizontal Size)
  - field DISCYSIZE (Discard Area Vertical Size)
- LCDC_BASECFG4: bit DISCEN (Discard Area Enable)

Each time the overlay window is resized and/or moved, these configuration registers must be reconfigured according to the new overlay window features.

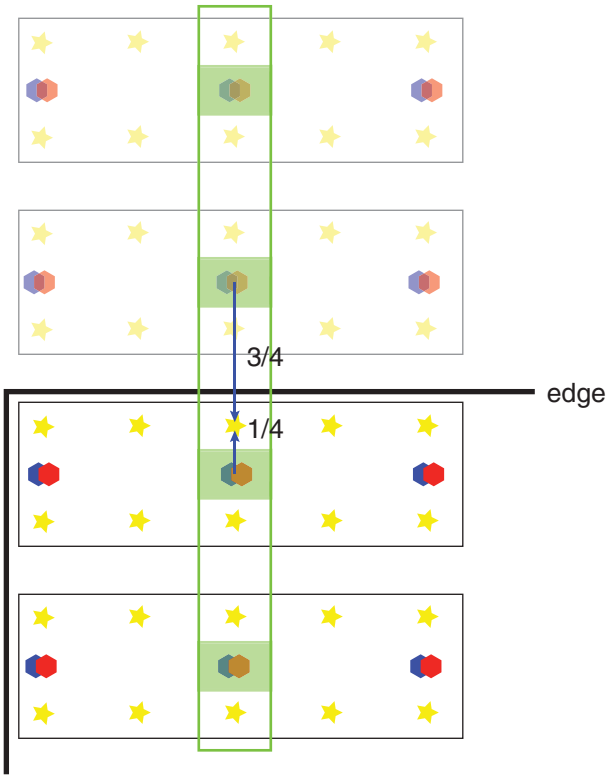
46.6.7. Contrast Brightness, Hue, and Saturation

This module is for YCbCr format purposes. Brightness offset adapts the luma component, hue is used for chroma phase adjustment, and color saturation for chroma amplitude. Contrast gain is applied on all pixel components (luma and chroma).

A black level compensation is also included for YCbCr limited range, when the Luma component is limited to 16-235 instead of 0-255 range. It consists of subtracting the minimum value for limited range (16) from the Luma component to obtain an output Luma range starting at 0, which corresponds to the full-range black level value.

Figure 46.3. CBHS Block Diagram

46.6.8. Chroma Upsampling Unit



The LCDC supports YCbCr4:2:2 and 4:2:0 frame buffers. In 4:2:2, the chroma components are sampled at half the luma rate. The horizontal resolution is halved.

In 4:2:0, the chroma components are also sampled at half the luma rate, vertically and horizontally.

When these modes are selected, the Unified Scaling Engine is used to resample the chroma component and interpolate the missing components.

46.6.9. Striding

The LCDC includes a technique to increment the memory address by a programmable amount when the end of line has been reached. This offset is referred to as XSTRIDE and is defined on a per layer basis. Additionally, the PSTRIDE field allows a programmable jump at the pixel level. Pixel stride is the value from one pixel to the next.

46.6.9.1. Line Striding

When the end of line has been reached, the DMA address counter points to the next pixel address. The channel DMA current address value is added to the XSTRIDE field, and then updated. If XSTRIDE is set to zero, the DMA address register remains unchanged. The XSTRIDE field of the channel configuration register is aligned to the pixel size boundary. The XSTRIDE field is a two's complement number. The following formula applies at the line boundary and indicates how the DMA controller computes the next pixel address. The function Sizeof() returns the number of bytes required to store a pixel.

$$\text{NextPixelAddress} = \text{CurrentPixelAddress} + \text{Sizeof}(\text{pixel}) + \text{XSTRIDE}$$

© 2026 Microchip Technology Inc. and its subsidiaries

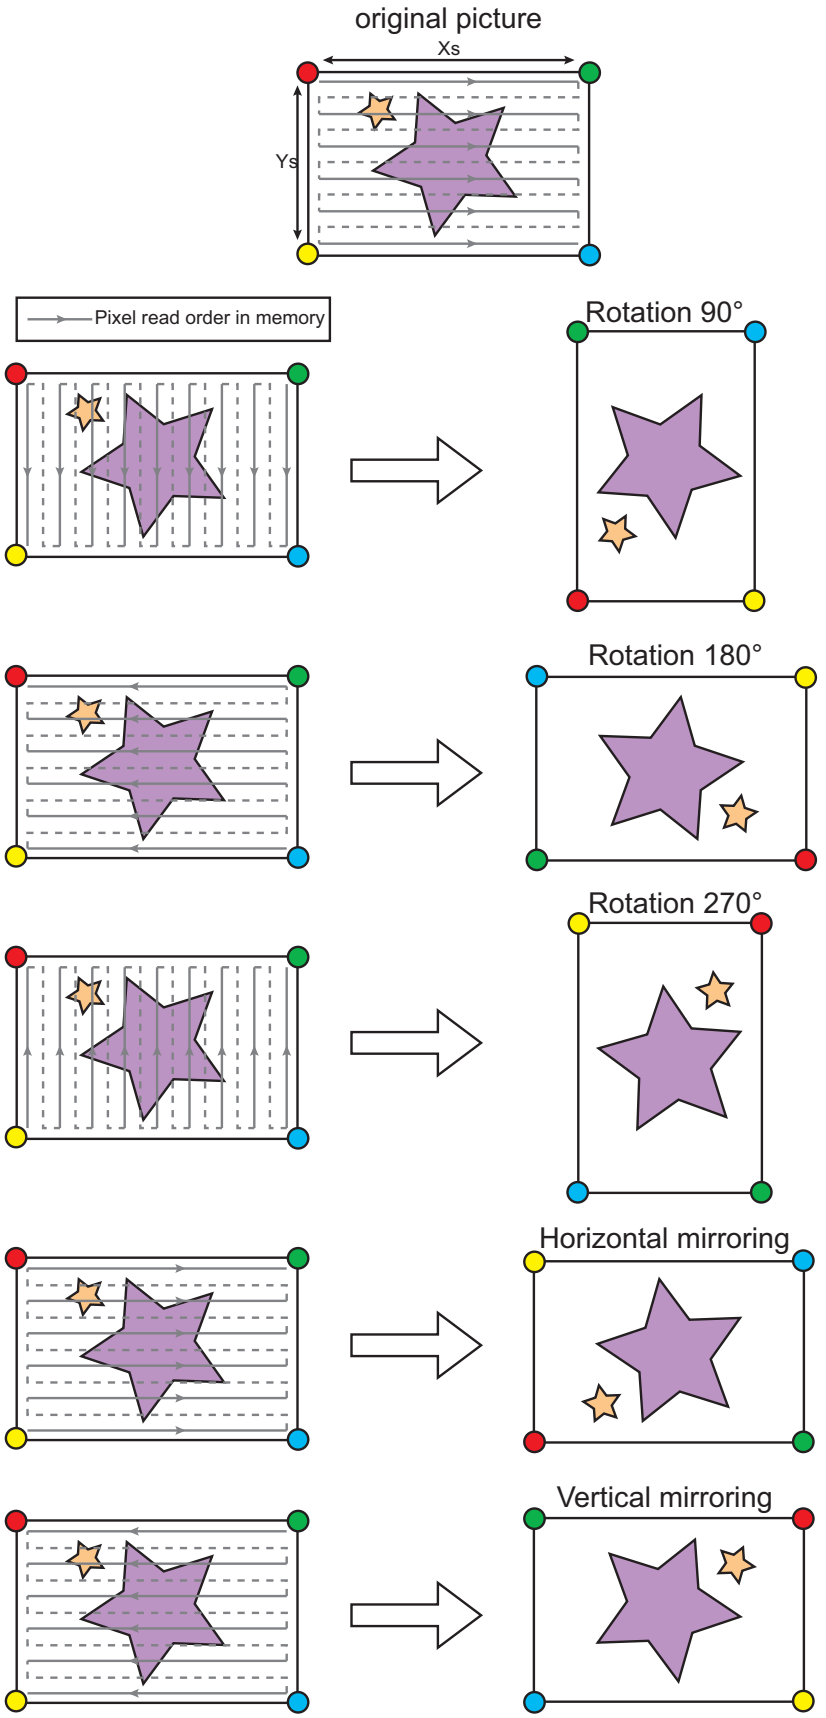
46.6.9.2.Pixel Striding

At each pixel, the DMA address counter points to the next pixel address. The channel DMA current address value is added to the PSTRIDE field and then updated. If PSTRIDE is set to 0, the DMA address register remains unchanged. The PSTRIDE field of the channel configuration register is aligned to the pixel size boundary. The PSTRIDE field is a two's complement number. The following formula applies at each pixel and indicates how the DMA controller computes the next pixel address. The function Sizeof() returns the number of bytes required to store a pixel.

$$\text{NextPixelAddress} = \text{CurrentPixelAddress} + \text{Sizeof}(\text{pixel}) + \text{PSTRIDE}$$

The Base Layer does not support pixel striding.

For overlays, pixel striding is not supported for the following modes:



- YCrCb 4:2:2 packed modes:
  - 16BPP_YCBCR_MODE0
  - 16BPP_YCBCR_MODE1
  - 16BPP_YCBCR_MODE2
  - 16BPP_YCBCR_MODE3
- CLUT modes less than 8bpp
  - CLUT_1BPP
  - CLUT_2BPP
  - CLUT_4BPP

46.6.9.3.Image Rotation And Mirroring

Image rotation or mirroring is produced by combining pixel and line striding to read image pixels in a different order, as shown in the figure below.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 46.7. Rotation and Mirroring

© 2026 Microchip Technology Inc. and its subsidiaries

The Configuration tables below show how to configure registers according to image transformation. The following notations are used:

- FPA = original image First Pixel Address
- Xs = original image horizontal number of pixels
- Ys = original image vertical number of pixels
- Ps = original image Pixel size expressed in byte (see Pixel Size Values)
- HXs = floor{(Xs+1)/2} , the rounded half of Xs
- HYs = floor{(Ys+1)/2} , the rounded half of Ys

Table 46.46. Pixel Size Values

Input Mode	Ps Value (in bytes)

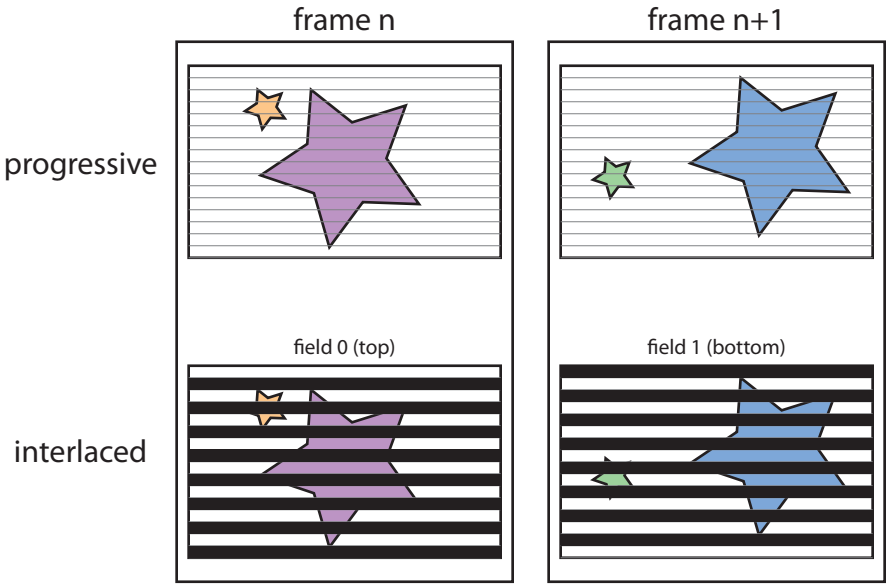
46.6.10. Gamma Correction



Imaging devices have non-linear characteristics, but the transfer function is approximated by a power function. The intensity of each of the linear RGB components is transformed to a non-linear signal through the use of the gamma correction submodule. The power function is approximated by using the four 256-entry Color LUT. The table values are programmable through the User Interface when the CLUT mode and gamma correction are disabled (CLUTEN and GAM fields of the Configuration register 1 of the layer are cleared), or by the DMA as described in Color Look-Up Table Configuration. Each ARGB component input value can be associated with the gamma corrected value written in the CLUT.

46.6.11. Interlaced Frame Content

The LCDC supports progressive and interlaced content. Interlaced video signals provide only half the lines in each frame. Two fields are used alternately, each containing half the lines of the original frame. The top field, with index 0, contains every other line, starting with the first line. The bottom field, with index 1, contains every other line, starting with the second line. This is illustrated in the figure below.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 46.8. Progressive and Interlaced Content

When this mode is selected, the Unified Scaling Engine is used to resample the current frame and interpolate the missing lines. To select Interlaced Content mode, set LCDC_HEOCFG1.ILD to one.

To handle both fields, specific configuration registers are duplicated depending on the field index, as described in the table below.

Table 46.57. Interlaced Configuration Registers

Field	Progressive	Interlaced Field 0 (Top)	Interlaced Field 1 (Bottom)
Frame buffer address	LCDC_HEOYFBA0 LCDC_HEOCBFBA0 LCDC_HEOCRFBA0		LCDC_HEOYFBA1 LCDC_HEOCBFBA1 LCDC_HEOCRFBA1
Scaling pixel alignment	LCDC_HEOCFG28.VXYOFF LCDC_HEOCFG28.VXCOFF LCDC_HEOCFG30.VXSYCFG LCDC_HEOCFG30.VXSCCFG		LCDC_HEOCFG28.VXYOFF1 LCDC_HEOCFG28.VXCOFF1 LCDC_HEOCFG30.VXSYCFG1 LCDC_HEOCFG30.VXSCCFG1

46.6.12. Color Space Conversion Unit

The color space conversion unit converts the Luma Chroma color space into the Red Green Blue (RGB) color space. The conversion matrix is defined below and is fully programmable through the User Interface.

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} \text{RYGAIN} & \text{RCBGAIN} & \text{RCRGAIN} \\ \text{GYGAIN} & \text{GCBGAIN} & \text{GCRGAIN} \\ \text{BYGAIN} & \text{BCBGAIN} & \text{BCRGAIN} \end{bmatrix} \cdot \begin{bmatrix} Y - \text{Yoff} \\ \text{Cb} - \text{Cboff} \\ \text{Cr} - \text{Croff} \end{bmatrix}$$

Color space conversion coefficients are defined with 1 sign bit, 2 integer bits and 10 fractional bits. The range of the ijGAIN coefficients is -4<ijGAIN<+4 with a step of 1/1024.

Additionally, a set scaling offset {Yoff=16, Cboff=128, Croff=128} can be applied by configuring LCDC_HEOCFG22.

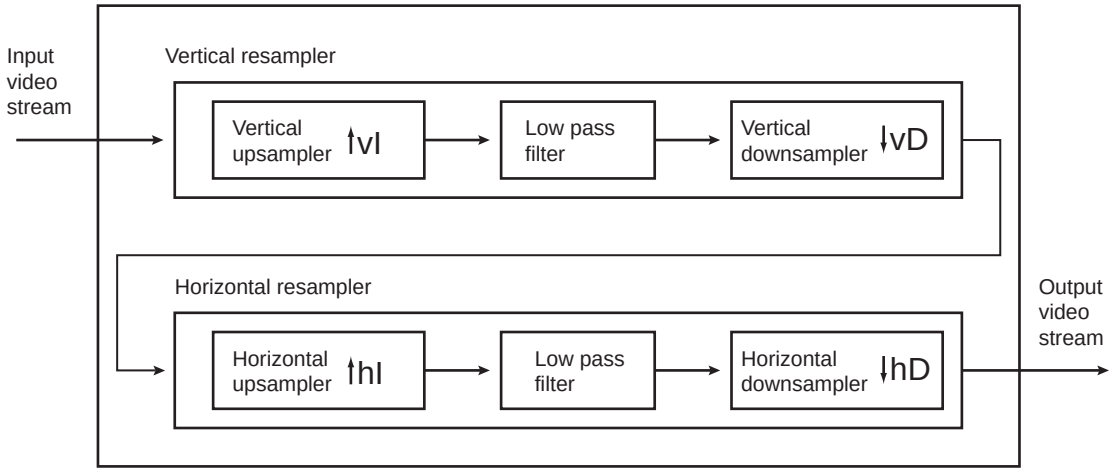
46.6.13. Unified Scaling Engine

The High-End Overlay (HEO) data path includes a multi-mode hardware scaler that allows an image resize in both the horizontal and the vertical directions. It performs chroma upsampling for YCbCr

© 2026 Microchip Technology Inc. and its subsidiaries

4:2:2 and YCbCr 4:2:0 formats, and also rescales the alpha channel. It integrates a two-tap or four-tap filter architecture with programmable polyphase coefficients or fixed bilinear interpolation coefficients.

46.6.13.1. Video Scaler Description



The scaling operation is based on a vertical and horizontal resampling algorithm. The sampling rate of the original image is increased when the video is upscaled, and decreased when the video is downscaled. A vertical resampler is used to perform vertical interpolation by a factor of vI, and a decimation by a factor of vD. A horizontal resampler is used to perform vertical interpolation by a factor of hI, and a decimation by a factor of hD. The horizontal and vertical low pass filters are both designed to minimize the aliasing effect. The frequency response of the low pass filter has the following characteristics:

$$H(\omega) = \begin{cases} I & \text{when } 0 \le |\omega| \le \min\left(\frac{\pi}{I}, \frac{\pi}{D}\right) \\ 0 & \text{otherwise} \end{cases}$$

Taking into account the linear phase condition and anticipating the filter length M, the desired frequency response is modified.

$$H(\omega) = \begin{cases} Ie^{-j\omega\frac{M}{2}} & \text{when } 0 \le |\omega| \le \min\left(\frac{\pi}{I}, \frac{\pi}{D}\right) \\ 0 & \text{otherwise} \end{cases}$$

Figure 46.9. Video Resampler Architecture

The impulse response of the defined low pass filter is:

$$h(n) = \begin{cases} I \times \frac{\omega_c}{\pi} \text{ when } n = 0 \\ I \times \frac{\omega_c}{\pi} \times \frac{\sin\omega cn}{\omega_c n} \text{otherwise} \end{cases}$$

Or, for the filter of length M:

$$h(n) = \begin{cases} I \times \frac{\omega_c}{\pi} \text{ when } n = \frac{M}{2} \\ I \times \frac{\omega_c}{\pi} \times \frac{\sin\omega cn - M2}{\omega_c\left(n - \frac{M}{2}\right)} \text{otherwise} \end{cases}$$

© 2026 Microchip Technology Inc. and its subsidiaries

This ideal filter is non-causal and cannot be realized. The unit sample response h(n) is infinite in duration and must be truncated depending on the expected length M of the filter. This truncation is equivalent to the multiplication of the impulse response by a window function w(n).

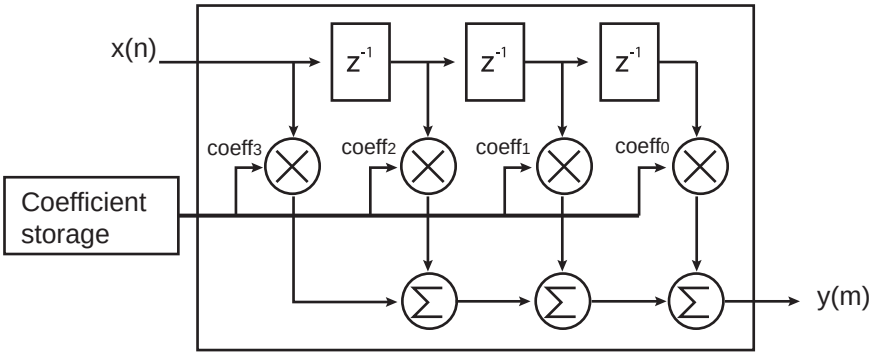
Table 46.58. Window Function for a Filter Length M

Name of Window Function	Time Domain Sequence w(n)
Barlett	$1 - \frac{2 \times \left\lvert n - \frac{M-1}{2} \right\rvert}{M-1}$
Blackman	$0.42 - 0.5 \times \cos 2\pi nM-1 + 0.08 \times \cos 4\pi nM-1$
Hamming	$0.54 - 0.46 \times \cos 2\pi nM-1$
Hanning	$0.5 - 0.5 \times \cos 2\pi nM-1$

The horizontal resampler includes a 16-phase 4-tap filter equivalent to a 64-tap FIR illustrated in Horizontal Resampler Filter Architecture below.

The vertical resampler includes a 16-phase 4-tap filter equivalent to a 64-tap FIR illustrated in Vertical Resampler Filter Architecture below.

Figure 46.10. Horizontal Resampler Filter Architecture



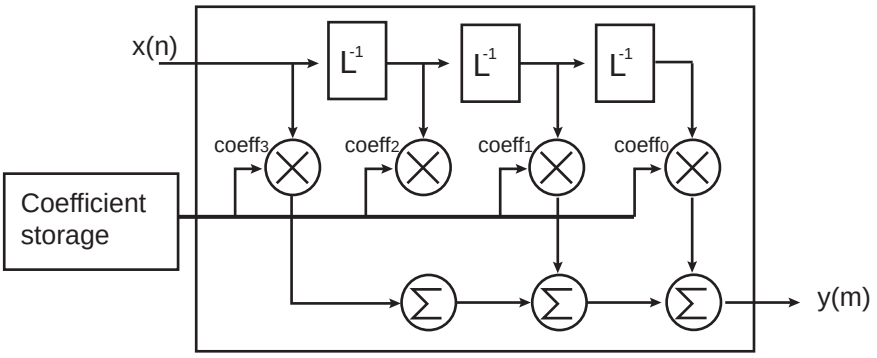


Figure 46.11. Vertical Resampler Filter Architecture

46.6.13.2.Horizontal Scaler Main Configuration

LCDC_HEOCFG4.XMEMSIZE indicates the horizontal size minus one of the image in the system memory. LCDC_HEOCFG3.XSIZE contains the horizontal size minus one of the window.

The YCbCr upsampling process requires that the horizontal scaler is composed of two channels. The first channel processes A and Y components (alph/luma) and the second channel processes Cb and Cr (chroma) components. Thus different scaling configurations are available for both channels.

© 2026 Microchip Technology Inc. and its subsidiaries

In modes other than YCbCr 4:2:2 or YCbCr 4:2:0, both channels must be configured similarly to preserve image integrity.

LCDC_HEOCFG23.HXSYEN and LCDC_HEOCFG23.HXSCEN, respectively for Alpha/Luma and chroma channels, are used to activate the scaler. The scaling factors are programmed in LCDC_HEOCFG26.HXSYFACT and LCDC_HEOCFG27.HXSCFACT, respectively for alpha/luma and chroma channels.

The following equation calculates the horizontal scaling factor (HFACTOR) value:

$$\mathrm{HFACTOR} = \mathrm{round}\left(\frac{2^{20} \times \mathrm{XMEMSIZE}}{\mathrm{XSIZE}}\right)$$

The values in HXSYFACT and HXSCFACT are 24 bits wide (4-bit integer part, 20-bit fractional part), hence the horizontal downsampling capacity is limited to 16.0.

When YCbCr 4:2:2, or YCbCr 4:2:0 formats are used to resample the output window, the value of HXSCFACT must consider chroma upsampling by taking the half of HFACTOR.

When YCbCr 4:2:2, or YCbCr 4:2:0 formats are used without resampling the output window, , LCDC_HEOCFG23.HXSYEN and LCDC_HEOCFG23.HXSCEN can be set to zero. The scaler engine is then internally configured to process chroma upsampling without any configuration of LCDC_HEOCFG26 and LCDC_HEOCFG27.

Scaler Use Cases provides register values according to the context.

46.6.13.3.Vertical Scaler

LCDC_HEOCFG4.YMEMSIZE indicates the vertical size minus one of the image in the system memory. LCDC_HEOCFG3.YSIZE contains the vertical size minus one of the window.

For the YCbCr upsampling process, the vertical scaler is composed of two channels. The first channel processes A and Y components (alpha/luma), the second channel processes Cb and Cr (chroma). This allows different scaling configurations for both channels. In modes other than YCbCr 4:2:2 or YCbCr 4:2:0, both channels must be configured similarly to preserve image integrity.

LCDC_HEOCFG23.VXSYEN LCDC_HEOCFG23.VXSCEN, respectively for Alpha/Luma and chroma channels, are used to activate the scaler. The scaling factors are programmed in LCDC_HEOCFG24.VXSYFACT and LCDC_HEOCFG25.VXSCFACT, respectively for alpha/luma and chroma channels.

Use the following equation to calculate the VFACTOR value:

$$\mathrm{VFACTOR} = \mathrm{round}\left(\frac{2^{20} \times \mathrm{YMEMSIZE}}{\mathrm{YSIZE}}\right)$$

The VXSYFACT and VXSCFACT fields values are 24 bits wide (4-bit integer part, 20-bit fractional part), hence the vertical downsampling capacity is limited to 16.0.

When YCbCr 4:2:0 formats are used with resampling of the output window, the VXSCFACT field value has to consider the chroma upsampling by taking the half of VFACTOR.

When YCbCr 4:2:2, or YCbCr 4:2:0 formats are used without resampling the output window, then the LCDC_HEOCFG23.VXSYEN and LCDC_HEOCFG23.VXSCEN can be set to zero. The scaler engine is then internally configured to process chroma upsampling without any configuration of LCDC_HEOCFG24 and LCDC_HEOCFG25.

When Interlaced mode is used, the vertical scaler must be enabled and configured as detailed in Interlaced YCbCr 4:2:0, Chroma Upsampling (cosited), Top/Bottom Interpolation, With Window Resampling Configuration.

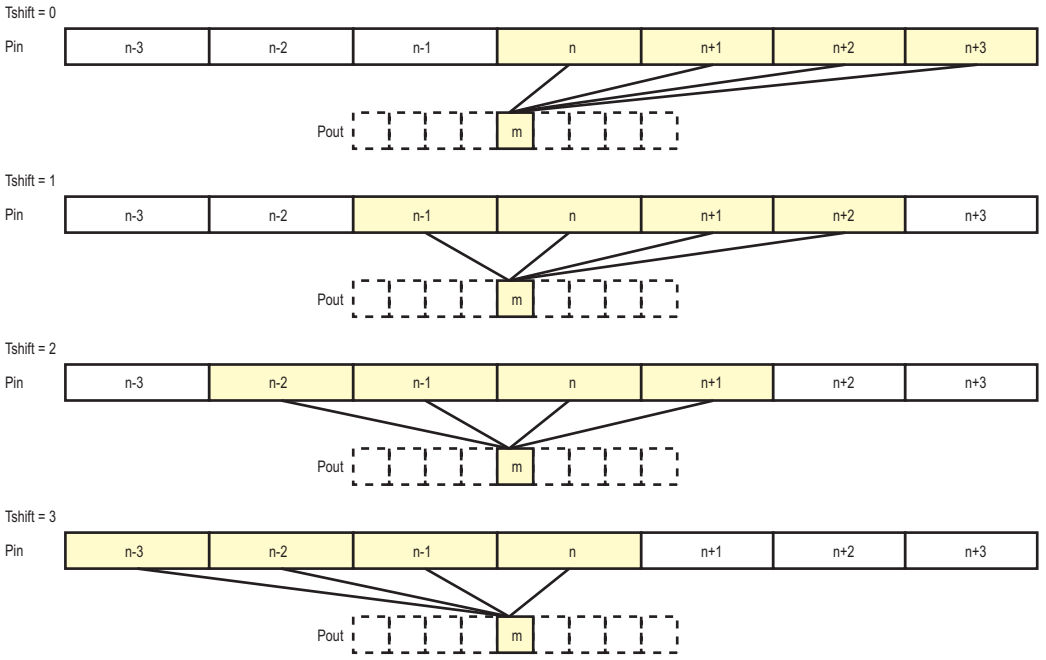
Scaler Use Cases provides register values according to the context.

© 2026 Microchip Technology Inc. and its subsidiaries

46.6.13.4.Input/Output Pixel Alignment

Depending on application requirements, output pixel alignment according to input pixels can be tuned for the horizontal and vertical scaler. This tuning modifies the position of the output image within the range of the filter length. Two different types of configuration fields are used, Filter Taps Shift and Filter Init Phase Offset. Each of them produces a filter spatial response shift as described below.

Filter Taps Shift determines which set of input pixels is used at filter input to process a given output pixel. The following equation shows how the output pixel is calculated through the filter:



$$\mathrm{Pout}(m) = \sum_{k=0}^{N-1} \mathrm{Pin}(n + N - 1 - k - \mathrm{Tshift}) \times h(k, p)$$

With :

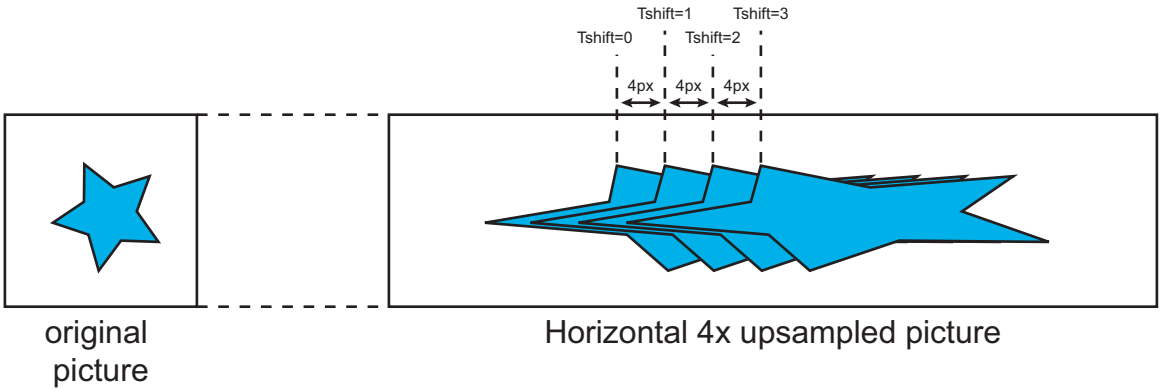
- Pin—input pixel component value (any A, R, G or B in ARGB mode, and A, Y, Cb or Cr in YCbCr mode)
- N—the filter number of taps (N=16)
- Tshift—Filter taps shift
- h(k, p)—Filter taps value depending on tap number k, and phase index p
- Pout—output pixel component value (A, R, G or B in ARGB mode, and A, Y, Cb or Cr in YCbCr mode)

The output image is shifted by the value Tshift/FACT. Figure 46.12 and Figure 46.13 illustrate an upsampling by 4 use case (FACT=0.25x2^{20}):

Figure 46.12. Filter Taps Shift

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 46.13. Filter Taps Shift Results for Different Horizontal Tshift Values (Upsampling by 4)



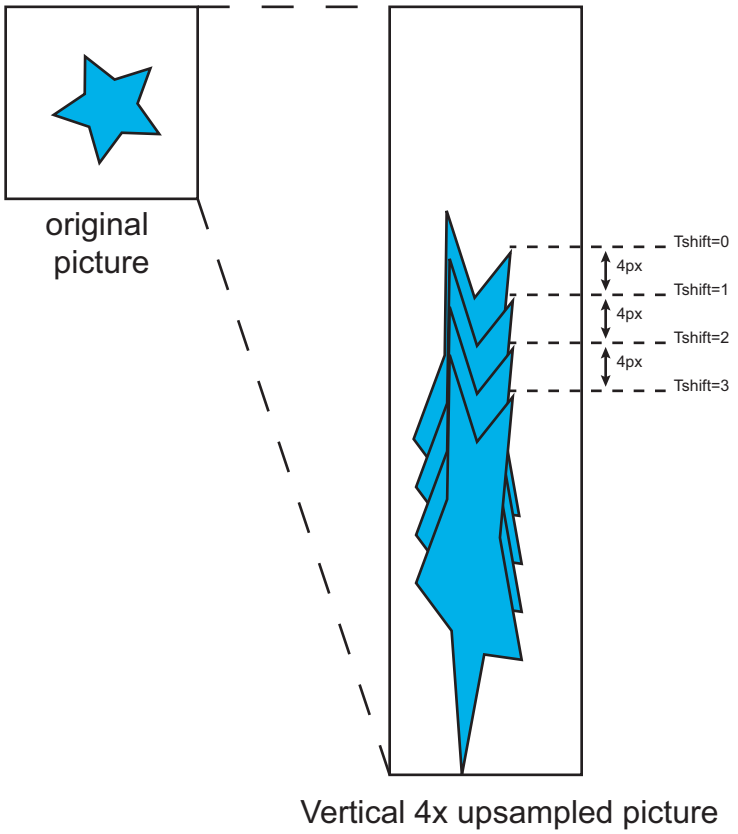


Figure 46.14. Filter Taps Shift Results for Different Vertical Tshift Values (Upsampling by 4)

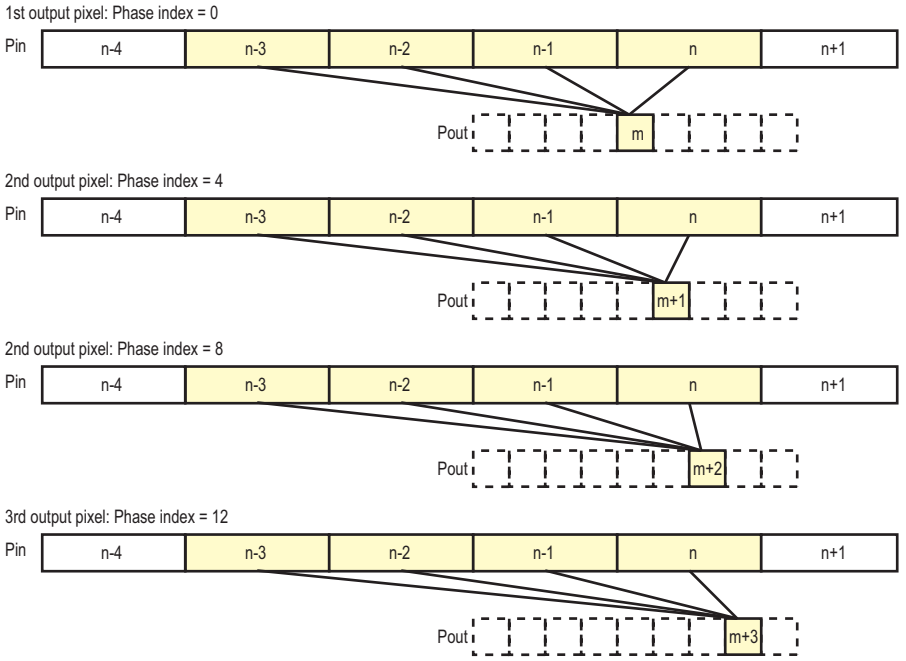
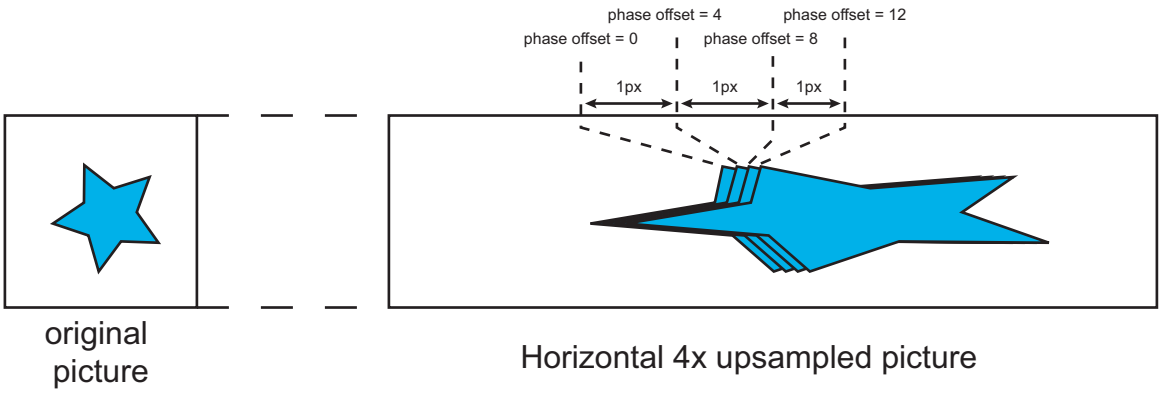
Filter taps shift Tshift is controlled by LCDC_HEOCFG30.HXSYCFG and LCDC_HEOCFG30.VXSCCFG for the horizontal scaler, and LCDC_HEOCFG30.VXSYCFG and LCDC_HEOCFG30.VXSCCFG for the vertical scaler.



LCDC_HEOCFG30.VXSYCFG1 and LCDC_HEOCFG30.VXSCCFG1 should also be considered in case of interlaced content.

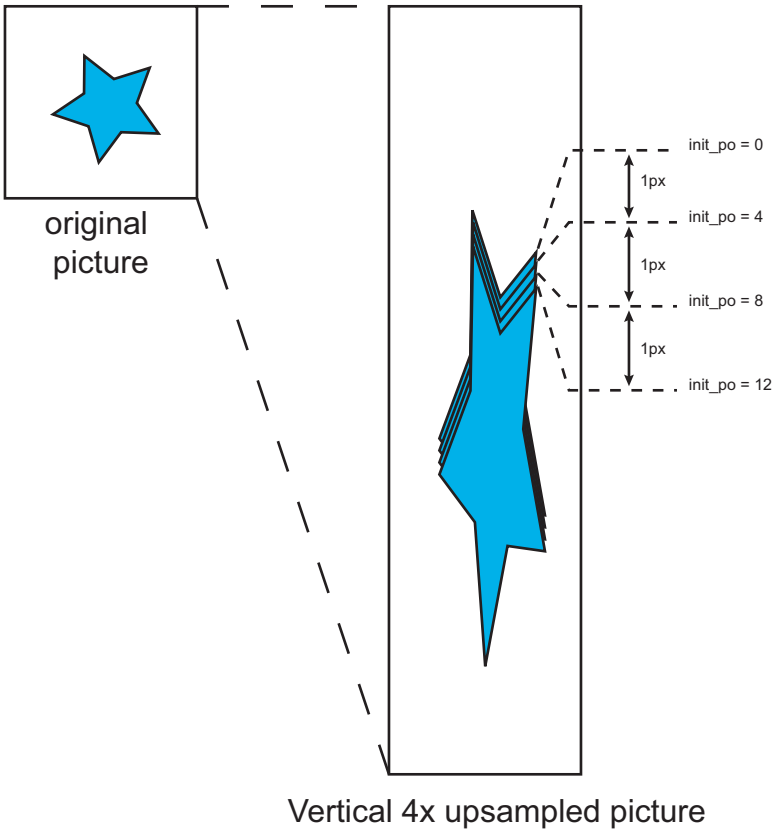
During the resampling process, a filter tap phase is selected for each output pixel, representing the fractional part of the output pixel spatial position, according to the input pixel width. An input pixel width is subsampled in 16 phases values, each corresponding to a subset of filter taps p. Phase 0 corresponds to 0 fractional shift. Incrementing the phase index by 1 corresponds to a spatial shift of 1/16 pixel width.

© 2026 Microchip Technology Inc. and its subsidiaries



The figure below illustrates an upsampling by 4 use case (4 output pixels for one input pixel), with a fixed Tshift value.

Figure 46.15. Filter Phase Index (Tshift = 3)



An additional phase offset can be configured in HEO_CFG28 and HEO_CFG29 and adds a fractional shift to all pixels of the frame. This is illustrated in the figure below for the use case when upsizing by 4.

Figure 46.16. Horizontal Initial Phase Offset On Upsizing by 4

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 46.17. Vertical Initial Phase Offset on Upsizing by 4

The initial phase offset is controlled by LCDC_HEOCFG29.HXSCOFF and LCDC_HEOCFG29.HXSYOFF for the horizontal scaler, and LCDC_HEOCFG28.VXSYOFF and LCDC_HEOCFG28.VXSCOFF for the vertical scaler.

LCDC_HEOCFG28.VXSYOFF1 and LCDC_HEOCFG28.VXSCOFF1 should also be considered in case of interlaced content.

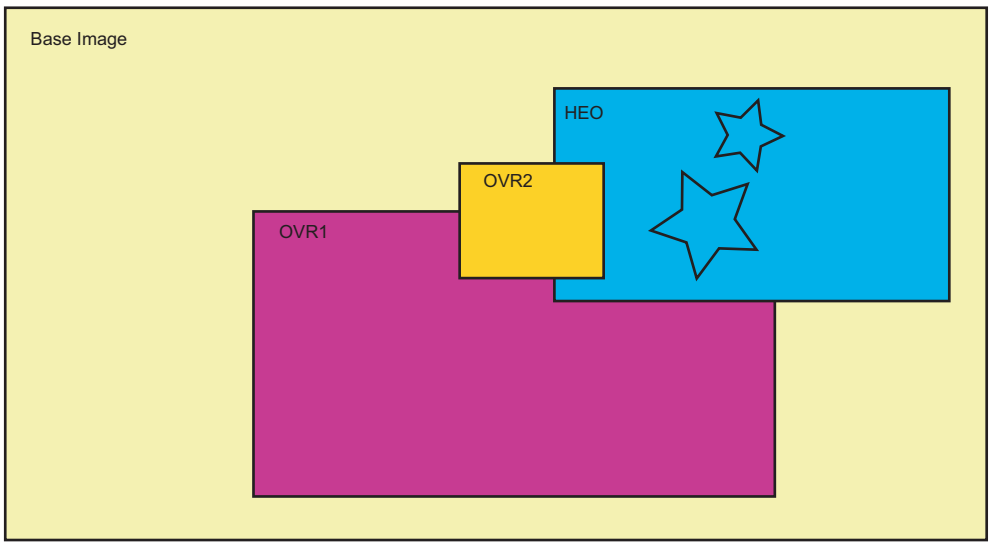
46.6.14. Color Combine Unit

46.6.14.1.Window Overlay



The LCDC provides hardware support for multiple “overlay planes” that can be used to display windows on top of the image without destroying the image located below. The overlay image can use any color depth. Using the overlay alleviates the need to re-render the occluded portion of the image. When pixels are combined together through the alpha blending unit, a new color is created. This new pixel is called an iterated pixel and is passed to the next blending stage. Then, this pixel may be combined again with another pixel. LCDC_HEOCFG12.VIDPRI configures the video priority algorithm used to display the layers. When VIDPRI is written to zero, the OVR1 layer is located above the HEO layer. When VIDPRI is written to one, OVR1 is located below the HEO layer.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 46.18. Overlay Example with Two Different Video Prioritization Algorithms

Video Prioritization Algorithm 1 : OVR2 > OVR1 > HEO > BASE

Video Prioritization Algorithm 2 : OVR2 > HEO > OVR1 > BASE

46.6.14.2.Overlay Blending

The blending function requires two pixels (one iterated from the previous blending stage and one from the current overlay color) and a set of blending configuration parameters. These parameters are separated according to component type: A for Alpha, or C for any color component R, G or B.

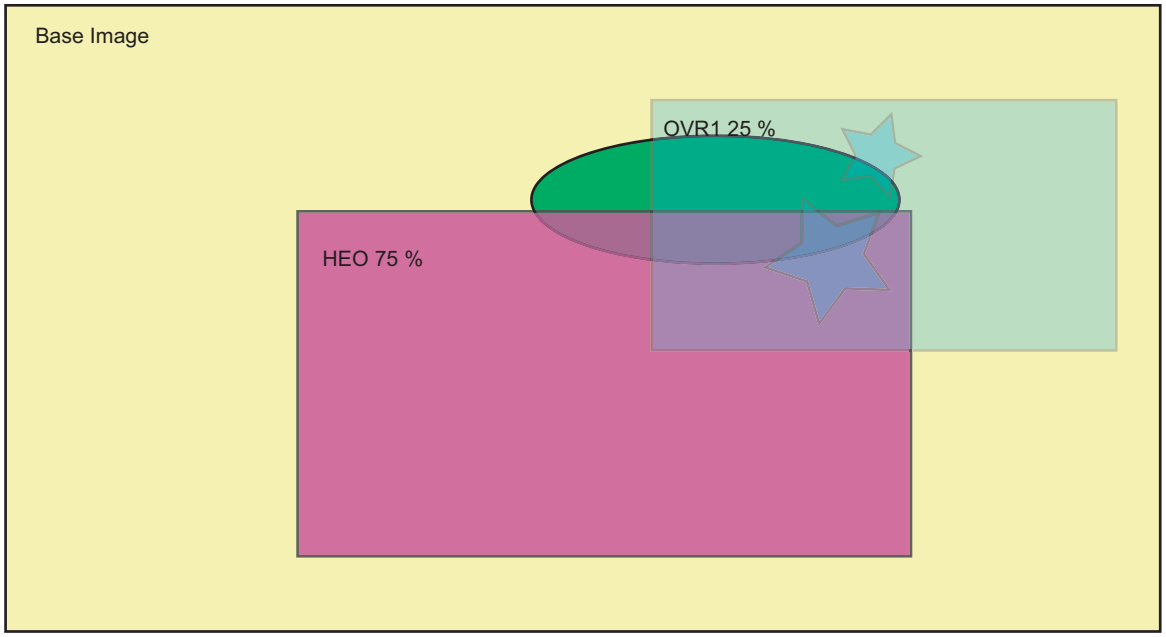
46.6.14.3.Window Blending

Figure 46.21. 256-level Alpha Blending



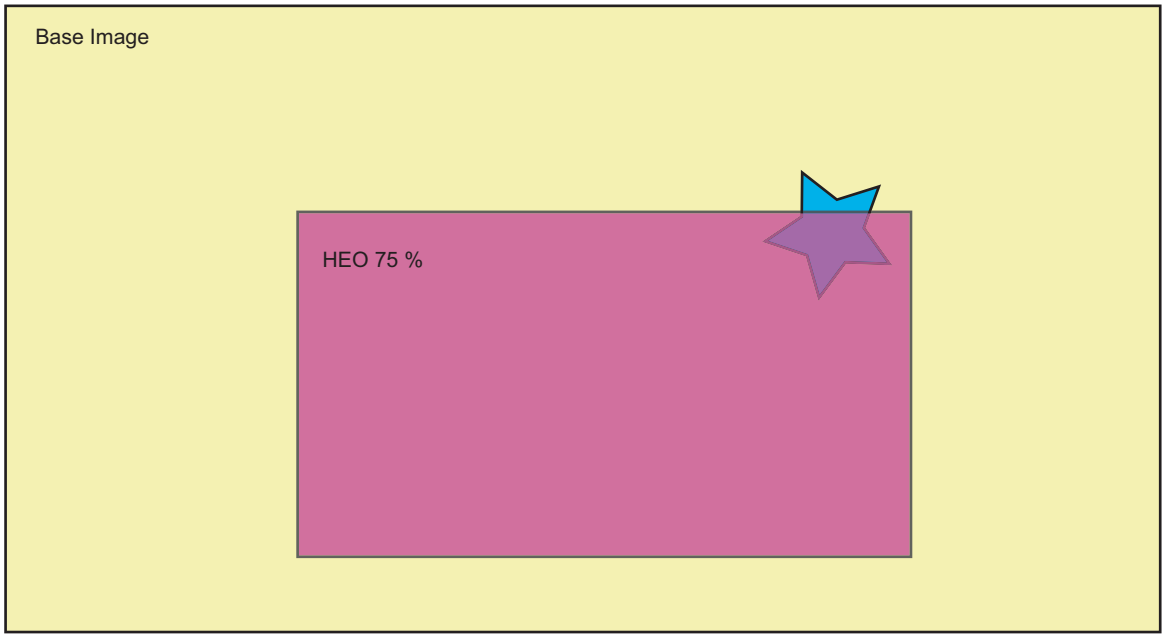


Figure 46.22. Figure 7-23. 256-level Alpha Blending

46.6.14.4.Color Keying

Color keying involves a method of bit-block image transfer (Blit). This entails blitting one image onto another where not all the pixels are copied. Blitting usually involves two bitmaps: a source bitmap and a destination bitmap. A raster operation (ROP) is performed to define whether the iterated color or the overlay color is to be visible or not.

© 2026 Microchip Technology Inc. and its subsidiaries

46.6.14.4.1.Source Color Keying

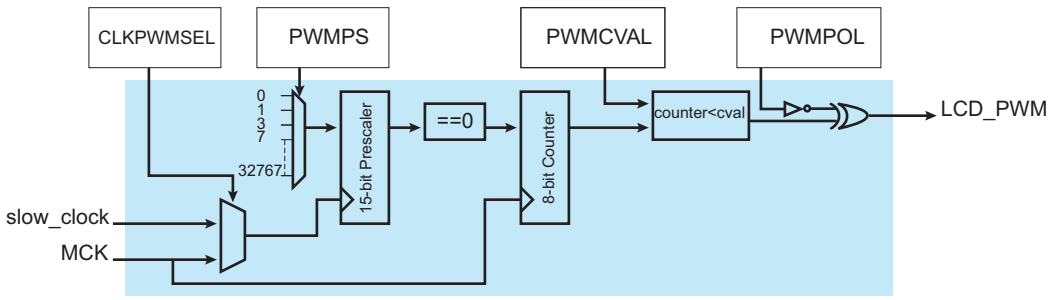
If the masked overlay color matches the color key, the iterated color is selected and Source Color Keying is activated using the following configuration sequence:

1. Select the overlay to blit.
2. Write a zero to DSTKEY.
3. Activate Color Keying by writing a one to CRKEY.
4. Configure the Color Key by writing RKEY, GKEY and BKEY fields.
5. Configure the Color Mask by writing RKEY, GKEY and BKEY fields.

When the field RMASK, GMASK, or BMASK is configured to zero, the comparison is disabled and the raster operation is activated.

46.6.14.4.2.Destination Color Keying

If the iterated masked color matches the color key then the overlay color is selected, Destination Color Keying is activated using the following configuration sequence:



1. Select the overlay to blit.
2. Write a one to DSTKEY.
3. Activate Color Keying by writing a one to CRKEY bit
4. Configure the Color Key by writing RKEY, GKEY and BKEY fields.
5. Configure the Color Mask by writing RKEY, GKEY and BKEY fields.

When the field RMASK, GMASK, or BMASK is configured to zero, the comparison is disabled and the raster operation is activated.

46.6.15. LCDC PWM Controller

The LCDC integrates a Pulse Width Modulation (PWM) Controller.

Figure 46.23. PWM Controller Block Diagram

This block generates the LCD contrast control signal (LCD_PWM) that controls the display's contrast by software. LCDC_PWM is an 8-bit PWM signal that can be converted to an analog voltage with a simple passive filter.

The PWM module has a free-running counter whose value is compared against a compare register (LCDC_LCDCFG6.PWMCVAL). If the value in the counter is less than that in the register, LCDC_PWM is asserted with the value in the compare register (LCDC_LCDCFG6.PWMCVAL). Otherwise, the opposite value is output. Thus, a periodic waveform with a pulse width proportional to the value in the compare register is generated.

Due to the comparison mechanism, the output pulse has a width between 0 and 255 PWM counter cycles. Thus, by adding a simple passive filter outside the chip, an analog voltage between 0 and (255/256) × V_{DD} can be obtained for the positive polarity case, or between (1/256) × V_{DD} and V_{DD} for the negative polarity case. Other voltage values can be obtained by adding active external circuitry.

© 2026 Microchip Technology Inc. and its subsidiaries

For PWM mode, the counter frequency can be adjusted to 16 different values using LCDC_LCDCFG6.PWMPS.

The PWM module can be fed with the slow clock or the peripheral clock (MCK), depending on LCDC_CFG0.CLKPWMSEL.

LCD display panels have different backlight specifications in terms of minimum/maximum values for PWM frequency. If the LCDC PWM frequency range does not match the LCD display panel, it is possible to use the standalone PWM Controller (refer to the section “Pulse Width Modulation Controller (PWM)”) to drive the backlight.

46.6.16. Register Write Protection

To prevent any single software error from corrupting LCDC behavior, certain registers in the address space can be write-protected by setting the bits WPCFGE, WPITE, WPCRE in the LCDC Write Protection Mode register (LCDC_WPMR).

If a write access to a write-protected register is detected, the Write Protection Violation Status (WPVS) flag in the LCDC Write Protection Status register (LCDC_WPSR) is set and the Write Protection Violation Source (WPVSRC) field indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading LCDC_WPSR.

46.6.17. LCD Overall Performance

46.6.17.1.Color Look-Up Table (CLUT)

Table 46.63. CLUT Pixel Performance

CLUT Mode	Pixels/Word	Pixel Striding (Rotation/Mirroring)	Scaling
1 bpp	32	Not supported	Supported
2 bpp	16	Not supported	Supported
4 bpp	8	Not supported	Supported
8 bpp	4	Supported	Supported

46.6.17.2.RGB Mode Fetch Performance

The table below shows the maximum theoretical bandwidth according to input modes in burst access. In case of random single pixel fetch (when PSTRIDE is not 0) in non-zero wait state memory, the actual bandwidth will be significantly reduced.

Table 46.64. RGB Mode Performance

RGB Mode	Pixels/Word Memory Burst Mode
12 bpp	2
16 bpp	2

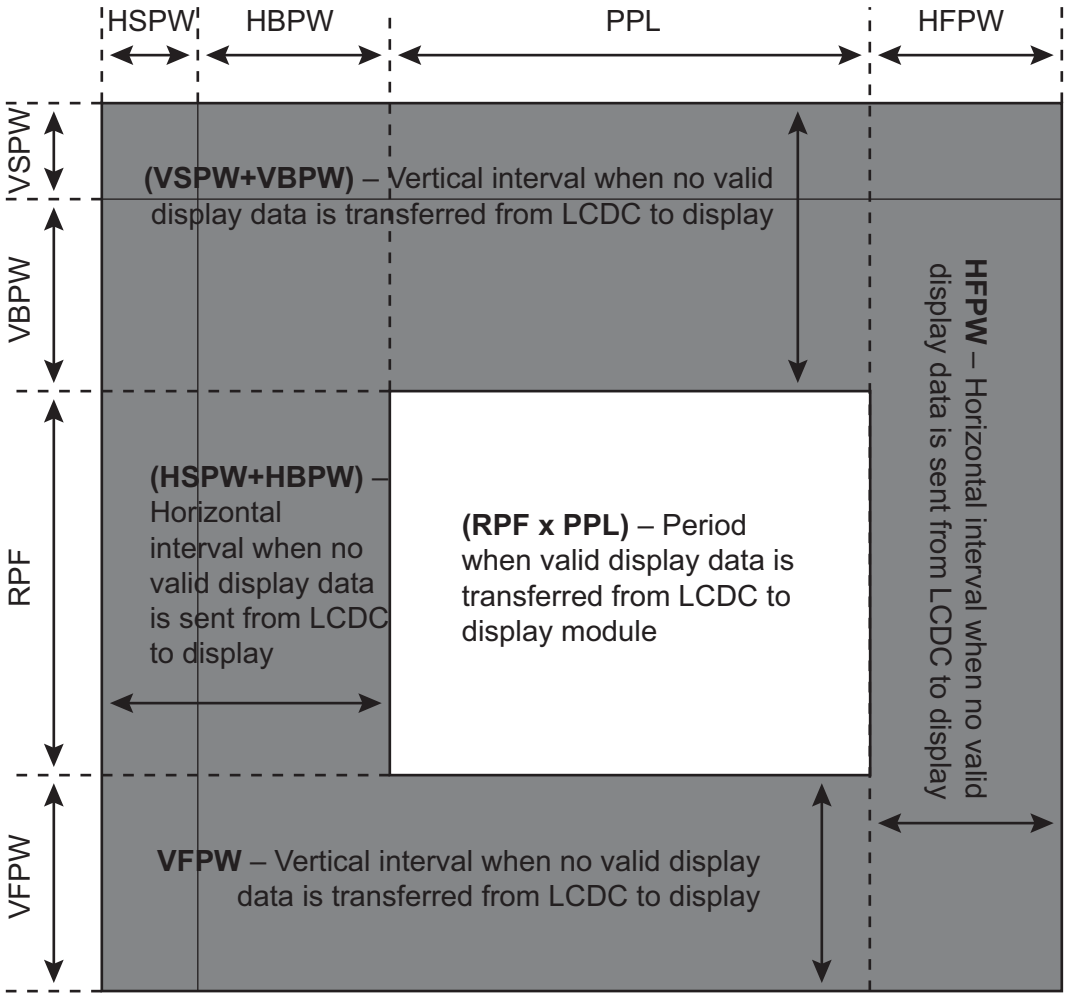
Table 46.66. YCbCr Planar Overall Capacity

YCbCr Mode	Pix/Word Memory Burst Mode
16 bpp 4:2:2 semiplanar	2
16 bpp 4:2:2 planar	2
12 bpp 4:2:0 semiplanar	2.66
12 bpp 4:2:0 planar	2.66

46.6.18. Input FIFO

The LCDC includes one input FIFO per layer. These input FIFOs are used to buffer the system bus burst and serialize the stream of pixels.



46.6.19. Output FIFO

The LCDC includes one output FIFO that stores the blended pixel.

46.7.1. LCDC Configuration Register 0

Name: LCDC_LCDCFG0
Offset: 0x00000000
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGE is cleared in the LCDC Write Protection Mode Register.

GCLK must be running before writing in this register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	CLKDIV[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
					CLKPWMSEL		CLKBYP	CLKPOL
Access					R/W		R/W	R/W
Reset					0		0	0

Bits 23:16 – CLKDIV[7:0] LCDC Clock Divider
8-bit width clock divider for pixel clock (LCDC_PCK). If CLKBYP = 0, the pixel clock frequency formula is:
LCDC_PCK_freq = GCLK_freq / (CLKDIV+2)

Bit 3 – CLKPWMSEL LCDC PWM Clock Source Selection

Value	Description
0	The slow clock is selected and feeds the PWM module.
1	The peripheral clock (MCK) is selected and feeds the PWM module.

Bit 1 – CLKBYP LCDC Pixel Clock Divider Bypass

Value	Description
0	Pixel clock divider is not bypassed. LCDC_PCK is defined with CLKDIV parameter.
1	Pixel clock divider is bypassed. LCDC_PCK = GCLK clock

Bit 0 – CLKPOL LCDC Clock Polarity

Value	Description
0	Data/Control signals are launched on the rising edge of the pixel clock.
1	Data/Control signals are launched on the falling edge of the pixel clock.

46.7.2. LCDC Configuration Register 1

Name: LCDC_LCDCFG1
Offset: 0x00000004
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGE is cleared in the LCDC Write Protection Mode Register.

GCLK must be running before writing in this register.

Bit	31	30	29	28	27	26	25	24
							VSPW[9:8]	
Access							R/W	R/W
Reset							0	0

Bit	23	22	21	20	19	18	17	16
	VSPW[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
							HSPW[9:8]	
Access							R/W	R/W
Reset							0	0

Bit	7	6	5	4	3	2	1	0
	HSPW[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 25:16 – VSPW[9:0] Vertical Synchronization Pulse Width
Width of the LCDC_VSYNC pulse, in number of lines. Width is (VSPW+1) lines.

Bits 9:0 – HSPW[9:0] Horizontal Synchronization Pulse Width
Width of the LCDC_HSYNC pulse, in pixel clock cycles. Width is (HSPW+1) LCDC_PCK cycles.

46.7.3. LCDC Configuration Register 2

Name: LCDC_LCDCFG2
Offset: 0x00000008
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGE is cleared in the LCDC Write Protection Mode Register.

GCLK must be running before writing in this register.

Bit	31	30	29	28	27	26	25	24
							VBPW[9:8]	
Access							R/W	R/W
Reset							0	0

Bit	23	22	21	20	19	18	17	16
	VBPW[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 25:16 – VBPW[9:0] Vertical Back Porch Width
Indicates the number of lines at the beginning of the frame. The blanking interval is equal to (VBPW+1) lines.

Bits 9:0 – VFPW[9:0] Vertical Front Porch Width
Indicates the number of lines at the end of the frame. The blanking interval is equal to (VFPW+1) lines.

46.7.4. LCDC Configuration Register 3

Name: LCDC_LCDCFG3
Offset: 0x0000000C
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGE is cleared in the LCDC Write Protection Mode Register.

GCLK must be running before writing in this register.

Bit	31	30	29	28	27	26	25	24
							HBPW[9:8]	
Access							R/W	R/W
Reset							0	0

Bit	23	22	21	20	19	18	17	16
	HBPW[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
							HFPW[9:8]	
Access							R/W	R/W
Reset							0	0

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 25:16 – HBPW[9:0] Horizontal Back Porch Width
Number of pixel clock cycles inserted at the beginning of the line. The interval is equal to (HBPW+1) LCDC_PCK cycles.

Bits 9:0 – HFPW[9:0] Horizontal Front Porch Width
Number of pixel clock cycles inserted at the end of the active line. The interval is equal to (HFPW+1) LCDC_PCK cycles.

46.7.5. LCDC Configuration Register 4

Name: LCDC_LCDCFG4
Offset: 0x00000010
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGE is cleared in the LCDC Write Protection Mode Register.

GCLK must be running before writing in this register.

Bit	31	30	29	28	27	26	25	24
						RPF[10:8]		
Access						R/W	R/W	R/W
Reset						0	0	0

Bit	23	22	21	20	19	18	17	16
	RPF[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
						PPL[10:8]		
Access						R/W	R/W	R/W
Reset						0	0	0

Bit	7	6	5	4	3	2	1	0
	PPL[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 26:16 – RPF[10:0] Number of Active Row Per Frame
Number of active lines in the frame. The frame height is equal to (RPF+1) lines.

Bits 10:0 – PPL[10:0] Number of Pixels Per Line
Number of pixels in the frame. The number of active pixels in the frame is equal to (PPL+1) pixels.

Access	R/W	R/W		R/W	R/W	R/W	R/W	R/W
Reset	0	0		0	0	0	0	0

Bits 23:16 – GUARDTIME[7:0] LCD Display Guard Time
Number of frames inserted during start-up before LCDC_DISP signal is enabled, and after LCDC_DISP signal is disabled.

Bit 13 – VSPHO LCDC Vertical Synchronization Pulse Hold Configuration

Value	Description
0	The vertical synchronization pulse is asserted synchronously with horizontal pulse edge.
1	The vertical synchronization pulse is held active one pixel clock cycle after the horizontal pulse.

Bit 12 – VSPSU LCDC Vertical Synchronization Pulse Setup Configuration

Value	Description
0	The vertical synchronization pulse is asserted synchronously with horizontal pulse edge.
1	The vertical synchronization pulse is asserted one pixel clock cycle before the horizontal pulse.

Bit 11 – DPI Display Pixel Interface Compatible Mode

Value	Description
0	Legacy pixel mapping.
1	Activates the DPI compliant pixel stream. See field MODE: LCDC Output Mode.

Bits 10:8 – MODE[2:0] LCDC Output Mode
DPI = 0:

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
0	OUTPUT_12BPP	LCD Output mode is set to 12 bits per pixel.
1	OUTPUT_16BPP	LCD Output mode is set to 16 bits per pixel.
2	OUTPUT_18BPP	LCD Output mode is set to 18 bits per pixel.
3	OUTPUT_24BPP	LCD Output mode is set to 24 bits per pixel.

Bit 7 – DISPDLY LCDC Display Power Signal Synchronization

Value	Description
0	The LCDC_DISP signal is asserted synchronously with the second active edge of the horizontal pulse.
1	The LCDC_DISP signal is asserted asynchronously with both edges of the horizontal pulse.

Bit 6 – DITHER LCDC Dithering

Value	Description
0	Dithering logical unit is disabled.
1	Dithering logical unit is activated.

Bit 4 – DISPPOL Display Signal Polarity

Value	Description
0	Active high.
1	Active low.

Bit 3 – VSPDLYE Vertical Synchronization Pulse End

Value	Description
0	The second active edge of the vertical synchronization pulse is synchronous with the second edge of the horizontal pulse.
1	The second active edge of the vertical synchronization pulse is synchronous with the first edge of the horizontal pulse.

Bit 2 – VSPDLYS Vertical Synchronization Pulse Start

Value	Description
0	The first active edge of the vertical synchronization pulse is synchronous with the second edge of the horizontal pulse.
1	The first active edge of the vertical synchronization pulse is synchronous with the first edge of the horizontal pulse.

Bit 1 – VSPOL Vertical Synchronization Pulse Polarity

Value	Description
0	Active high.
1	Active low.

Bit 0 – HSPOL Horizontal Synchronization Pulse Polarity

Value	Description
0	Active high.
1	Active low.

Bits 23:16 – GUARDTIME[7:0] LCD Display Guard Time
Number of frames inserted during start-up before LCDC_DISP signal is enabled, and after LCDC_DISP signal is disabled.

Bit 13 – VSPHO LCDC Vertical Synchronization Pulse Hold Configuration

Value	Description
0	The vertical synchronization pulse is asserted synchronously with horizontal pulse edge.
1	The vertical synchronization pulse is held active one pixel clock cycle after the horizontal pulse.

Bit 12 – VSPSU LCDC Vertical Synchronization Pulse Setup Configuration

Value	Description
0	The vertical synchronization pulse is asserted synchronously with horizontal pulse edge.
1	The vertical synchronization pulse is asserted one pixel clock cycle before the horizontal pulse.

Bit 11 – DPI Display Pixel Interface Compatible Mode

Value	Description
0	Legacy pixel mapping.
1	Activates the DPI compliant pixel stream. See field MODE: LCDC Output Mode.

Bits 10:8 – MODE[2:0] LCDC Output Mode
DPI = 1:

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
0	OUTPUT_DPI_16BPPCFG1	LCD Output mode is set to 16 bits per pixel Configuration 1.
1	OUTPUT_DPI_16BPPCFG2	LCD Output mode is set to 1 bits per pixel Configuration 2.
2	OUTPUT_DPI_16BPPCFG3	LCD Output mode is set to 16 bits per pixel Configuration 3.
3	OUTPUT_DPI_18BPPCFG1	LCD Output mode is set to 18 bits per pixel Configuration 1.
4	OUTPUT_DPI_18BPPCFG2	LCD Output mode is set to 18 bits per pixel Configuration 2.
5	OUTPUT_DPI_24BPP	LCD Output mode is set to 24 bits per pixel.

Bit 7 – DISPDLY LCDC Display Power Signal Synchronization

Value	Description
0	The LCDC_DISP signal is asserted synchronously with the second active edge of the horizontal pulse.
1	The LCDC_DISP signal is asserted asynchronously with both edges of the horizontal pulse.

Bit 6 – DITHER LCDC Dithering

Value	Description
0	Dithering logical unit is disabled.
1	Dithering logical unit is activated.

Bit 4 – DISPPOL Display Signal Polarity

Value	Description
0	Active high.
1	Active low.

Bit 3 – VSPDLYE Vertical Synchronization Pulse End

Value	Description
0	The second active edge of the vertical synchronization pulse is synchronous with the second edge of the horizontal pulse.
1	The second active edge of the vertical synchronization pulse is synchronous with the first edge of the horizontal pulse.

Bit 2 – VSPDLYS Vertical Synchronization Pulse Start

Value	Description
0	The first active edge of the vertical synchronization pulse is synchronous with the second edge of the horizontal pulse.
1	The first active edge of the vertical synchronization pulse is synchronous with the first edge of the horizontal pulse.

Bit 1 – VSPOL Vertical Synchronization Pulse Polarity

Value	Description
0	Active high.
1	Active low.

Bit 0 – HSPOL Horizontal Synchronization Pulse Polarity

Value	Description
0	Active high.
1	Active low.

46.7.8. LCDC Configuration Register 6

Name: LCDC_LCDCFG6
Offset: 0x00000018
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGE is cleared in the LCDC Write Protection Mode Register.

GCLK must be running before writing in this register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	PWMCVAL[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
				PWMPOL	PWMPS[3:0]			
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	0	0	0

Bits 15:8 – PWMCVAL[7:0] LCDC PWM Compare Value
PWM compare value. Used to adjust the analog value obtained after an external filter to control the contrast of the display.

Bit 4 – PWMPOL LCDC PWM Signal Polarity
Defines the polarity of the PWM output signal.

Value	Description
0	The output pulses are low level.
1	The output pulses are high level (the output is high whenever the value in the counter is less than the value PWMCVAL).

Bits 3:0 – PWMPS[3:0] PWM Clock Prescaler
Selects the configuration of the counter prescaler module.

Value	Name	Description
0	DIV_1	The counter advances at a rate of $f_{COUNTER} = f_{PWM_SELECTED_CLOCK}$
1	DIV_2	The counter advances at a rate of $f_{COUNTER} = f_{PWM_SELECTED_CLOCK/2}$
2	DIV_4	The counter advances at a rate of $f_{COUNTER} = f_{PWM_SELECTED_CLOCK/4}$
3	DIV_8	The counter advances at a rate of $f_{COUNTER} = f_{PWM_SELECTED_CLOCK/8}$
4	DIV_16	The counter advances at a rate of $f_{COUNTER} = f_{PWM_SELECTED_CLOCK/16}$
5	DIV_32	The counter advances at a of rate $f_{COUNTER} = f_{PWM_SELECTED_CLOCK/32}$
6	DIV_64	The counter advances at a of rate $f_{COUNTER} = f_{PWM_SELECTED_CLOCK/64}$
7	DIV_128	The counter advances at a of rate $f_{COUNTER} = f_{PWM_SELECTED_CLOCK/128}$
8	DIV_256	The counter advances at a of rate $f_{COUNTER} = f_{PWM_SELECTED_CLOCK/256}$

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
9	DIV_512	The counter advances at a of rate $f_{COUNTER} = f_{PWM_SELECTED_CLOCK/512}$
10	DIV_1024	The counter advances at a of rate $f_{COUNTER} = f_{PWM_SELECTED_CLOCK/1024}$
11	DIV_2048	The counter advances at a of rate $f_{COUNTER} = f_{PWM_SELECTED_CLOCK/2048}$
12	DIV_4096	The counter advances at a of rate $f_{COUNTER} = f_{PWM_SELECTED_CLOCK/4096}$
13	DIV_8192	The counter advances at a of rate $f_{COUNTER} = f_{PWM_SELECTED_CLOCK/8192}$
14	DIV_16384	The counter advances at a of rate $f_{COUNTER} = f_{PWM_SELECTED_CLOCK/16384}$
15	DIV_32768	The counter advances at a of rate $f_{COUNTER} = f_{PWM_SELECTED_CLOCK/32768}$

46.7.9. LCDC Configuration Register 7

Name: LCDC_LCDCFG7
Offset: 0x0000001C
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGE is cleared in the LCDC Write Protection Mode Register.

GCLK must be running before writing in this register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
						ROW[10:8]		
Access						R/W	R/W	R/W
Reset						0	0	0

Bit	7	6	5	4	3	2	1	0
	ROW[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 10:0 – ROW[10:0] Row Identifier For Row Interrupt Signal
When the LCDC timing engine row pointer reaches the field ROW, an interrupt is triggered.
Indicates a line in reverse order, i.e., ROW0 is the last line and ROW height-1 the first line displayed.

© 2026 Microchip Technology Inc. and its subsidiaries

46.7.10. LCDC Enable Register

Name: LCDC_LCDEN
Offset: 0x00000020
Reset: –
Property: Write-only

This register can only be written if WPCRE is cleared in the LCDC Write Protection Mode Register.

GCLK must be running before writing in this register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
		CMEN	SDEN		PWMEN	DISPEN	SYNCEN	CLKEN
Access		W	W		W	W	W	W
Reset		–	–		–	–	–	–

Bit 6 – CMEN Color Mode Signal Enable

Value	Description
0	No effect.
1	Sets the color mode signal (lcd_cm) to one. If a rising edge is generated, signals the MIPI DSI host to send a “Color Mode On” command to the LCD screen when the MIPI output interface is selected.

Bit 5 – SDEN Shutdown Signal Enable

Value	Description
0	No effect.
1	Sets the shutdown signal (lcd_sd) to zero (turns on the display).

Bit 3 – PWMEN LCDC Pulse Width Modulation Enable

Value	Description
0	No effect.
1	PWM is enabled.

Bit 2 – DISPEN LCDC DISP Signal Enable

Value	Description
0	No effect.
1	LCDC_DISP signal is generated.

Bit 1 – SYNCEN LCDC Horizontal and Vertical Synchronization Enable

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	No effect.
1	Both horizontal and vertical synchronization (LCD_VSYNC and LCD_HSYNC) signals are generated.

Bit 0 – CLKEN LCDC Pixel Clock Enable

Value	Description
0	No effect.
1	Pixel clock logical unit is activated.

© 2026 Microchip Technology Inc. and its subsidiaries

46.7.11. LCDC Disable Register

Name: LCDC_LCDDIS
Offset: 0x00000024
Reset: –
Property: Write-only

This register can only be written if WPCRE is cleared in the LCDC Write Protection Mode Register.

GCLK must be running before writing in this register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
					PWMRST	DISPRST	SYNCRST	CLKRST
Access					W	W	W	W
Reset					–	–	–	–

Bit	7	6	5	4	3	2	1	0
		CMDIS	SDDIS		PWMDIS	DISPDIS	SYNCDIS	CLKDIS
Access		W	W		W	W	W	W
Reset		–	–		–	–	–	–

Bit 11 – PWMRST LCDC PWM Reset

Value	Description
0	No effect.
1	Resets the PWM module immediately. The duty cycle may be violated.

Bit 10 – DISPRST LCDC DISP Signal Reset

Value	Description
0	No effect.
1	Resets the DISP signal immediately.

Bit 9 – SYNCRST LCDC Horizontal and Vertical Synchronization Reset

Value	Description
0	No effect.
1	Resets the timing engine immediately. The horizontal and vertical pulse widths are both violated.

Bit 8 – CLKRST LCDC Clock Reset

Value	Description
0	No effect.
1	Resets the pixel clock generator module immediately. The pixel clock duty cycle may be violated.

Bit 6 – CMDIS Color Mode Signal Disable

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	No effect.
1	Sets the color mode signa (lcd_cm) to one. If a falling edge is generated, signals the MIPI DSI host to send a “Color Mode Off” command to the LCD screen when the MIPI output interface is selected).

Bit 5 – SDDIS Shutdown Signal Disable

Value	Description
0	No effect.
1	Sets the shutdown signal (lcd_sd) to one (turns off the display).

Bit 3 – PWMDIS LCDC Pulse Width Modulation Disable

Value	Description
0	No effect.
1	Disables the pulse width modulation signal after the end of the frame.

Bit 2 – DISPDIS LCDC DISP Signal Disable

Value	Description
0	No effect.
1	Disables the DISP signal after the end of the frame.

Bit 1 – SYNCDIS LCDC Horizontal and Vertical Synchronization Disable

Value	Description
0	No effect.
1	Disables the synchronization signals after the end of the frame.

Bit 0 – CLKDIS LCDC Pixel Clock Disable

Value	Description
0	No effect.
1	Disables the pixel clock after the end of the frame.

© 2026 Microchip Technology Inc. and its subsidiaries

46.7.12. LCDC Status Register

Name: LCDC_LCDSR
Offset: 0x00000028
Reset: 0x00000020
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

		CMSTS	SDSTS	SIPSTS	PWMSTS	DISPSTS	LCDSTS	CLKSTS
Access		R	R	R	R	R	R	R
Reset		0	1	0	0	0	0	0

Bit 6 – CMSTS Color Mode Signal Status

Value	Description
0	Color mode signal output is zero.
1	Color mode signal output is one.

Bit 5 – SDSTS Shutdown Signal Status

Value	Description
0	Shutdown signal output is zero.
1	Shutdown signal output is one.

Bit 4 – SIPSTS Synchronization In Progress

Value	Description
0	Clock domain synchronization is terminated.
1	Synchronization is in progress. Access to the registers LCDC_LCDCCFG[0..7], LCDC_LCDEN and LCDC_LCDDIS has no effect.

Bit 3 – PWMSTS LCDC PWM Signal Status

Value	Description
0	PWM is disabled.
1	PWM signal is activated.

Bit 2 – DISPSTS LCDC DISP Signal Status

Value	Description
0	DISP is disabled.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	DISP signal is activated.

Bit 1 – LCDSTS LCDC Synchronization Status

Value	Description
0	Timing engine is disabled.
1	Timing engine is running.

Bit 0 – CLKSTS Clock Status

Value	Description
0	Pixel clock is disabled.
1	Pixel clock is running.

© 2026 Microchip Technology Inc. and its subsidiaries

46.7.13. LCDC Interrupt Enable Register

Name: LCDC_LCDIER
Offset: 0x0000002C
Reset: –
Property: Write-only

This register can only be written if WPITE is cleared in the LCDC_WPMR.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24

Bit	7	6	5	4	3	2	1	0
				FIFOERR	ROW	DISP	DIS	SOF
Access				R	R	R	R	R
Reset				0	0	0	0	0

Bit 31 – WP Write Protection Interrupt Status

Value	Description
0	No Write Protection interrupt detected since last read of LCDC_LCDISR.
1	Indicates that a Write Protection error has been detected. This flag is reset after a read operation.

Bit 11 – HEO High-End Overlay Raw Interrupt Status

Value	Description
0	No High-End layer interrupt detected since last read of LCDC_HEOISR.
1	Indicates that a High-End layer interrupt is pending. This flag is reset as soon as the LCDC_HEOISR is read.

Bit 10 – OVR2 Overlay 2 Raw Interrupt Status

Value	Description
0	No Overlay 2 layer interrupt detected since last read of LCDC_OVR2ISR.
1	Indicates that an Overlay 2 layer interrupt is pending. This flag is reset as soon as the LCDC_OVR2ISR is read.

Bit 9 – OVR1 Overlay 1 Raw Interrupt Status

Value	Description
0	No Overlay 1 layer interrupt detected since last read of LCDC_OVR1ISR.
1	Indicates that an Overlay 1 layer interrupt is pending. This flag is reset as soon as the LCDC_OVR1ISR is read.

Bit 8 – BASE Base Layer Raw Interrupt Status

Value	Description
0	No base layer interrupt detected since last read of LCDC_BASEISR.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	Indicates that a base layer interrupt is pending. This flag is reset as soon as the LCDC_BASEISR is read.

Bit 4 – FIFOERR Output FIFO Error

Value	Description
0	No underflow has occurred in the output FIFO since last read of LCDC_LCDISR.
1	Indicates that an underflow has occurred in the output FIFO. This flag is reset after a read operation.

Bit 3 – ROW Row Interrupt Status

Value	Description
0	No detection since last read of the LCDC_LCDCISR.
1	Indicates that a row event has been detected. This flag is reset after a read operation.

Bit 2 – DISP Power-up/Power-down Sequence Terminated Interrupt Status

Value	Description
0	Power-up sequence or power-down sequence has not yet terminated.
1	Indicates the power-up sequence or power-down sequence has terminated. This flag is reset after a read operation.

Bit 1 – DIS LCD Disable Interrupt Status

Value	Description
0	Horizontal and vertical timing generator has not yet been disabled.
1	Indicates that the horizontal and vertical timing generator has been disabled. This flag is reset after a read operation.

Bit 0 – SOF Start of Frame Interrupt Status

Value	Description
0	No detection since last read of LCDC_LCDISR.
1	Indicates that a start of frame event has been detected. This flag is reset after a read operation.

Access					W	W	W	W
Reset					–	–	–	–

Bit 11 – HEOCL High-End Overlay Update Color LUT

Value	Description
0	No effect.
1	DMA update request for the HEO layer CLUT content.

Bit 10 – OVR2CL Overlay 2 Update Color LUT

Value	Description
0	No effect.
1	DMA update request for the OVR2 layer CLUT content.

Bit 9 – OVR1CL Overlay 1 Update Color LUT

Value	Description
0	No effect.
1	DMA update request for the OVR1 layer CLUT content.

Bit 8 – BASECL Base Layer Update Color LUT

Value	Description
0	No effect.
1	DMA update request for the base layer CLUT content.

Bit 3 – HEO High-End Overlay Update Attribute

Value	Description
0	No effect.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	Updates the HEO window attribute.

Bit 2 – OVR2 Overlay 2 Update Attribute

Value	Description
0	No effect.
1	Updates the OVR2 window attribute.

Bit 1 – OVR1 Overlay 1 Update Attribute

Value	Description
0	No effect.
1	Updates the OVR1 window attribute.

Bit 0 – BASE Base Layer Update Attribute

Value	Description
0	No effect.
1	Updates the base window attributes.

Access					R	R	R	R
Reset					0	0	0	0

Bit 31 – SIP Synchronization In Progress

Value	Description
0	Clock domain synchronization is terminated.
1	Synchronization is in progress. Access to LCDC_ATTRE has no effect.

Bit 11 – HEOCL High-End Overlay Color Table Status

Value	Description
0	No effect.
1	Indicates that an update request is pending for the High-end Overlay CLUT.

Bit 10 – OVR2CL Overlay 2 Color Table Status

Value	Description
0	No effect.
1	Indicates that an update request is pending for the Overlay 2 CLUT.

Bit 9 – OVR1CL Overlay 1 Color Table Status

Value	Description
0	No effect.
1	Indicates that an update request is pending for the Overlay 1 CLUT.

Bit 8 – BASECL Base Layer Color Table Status

Value	Description
0	No effect.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	Indicates that an update request is pending for the base CLUT.

Bit 3 – HEO High-End Overlay Update Status

Value	Description
0	No effect.
1	Indicates that an update request is pending for High-end Overlay.

Bit 2 – OVR2 Overlay 2 Update Status

Value	Description
0	No effect.
1	Indicates that an update request is pending for the Overlay 2 layer.

Bit 1 – OVR1 Overlay 1 Update Status

Value	Description
0	No effect.
1	Indicates that an update request is pending for the Overlay 1 layer.

Bit 0 – BASE Base Layer Update Status

Value	Description
0	No effect.
1	Indicates that an update request is pending for the base layer.

Access						R	R	R
Reset						0	0	0

Bit 2 – OVF Overflow Detected

Value	Description
0	No overflow occurred since last read of LCDC_BASEISR.
1	An overflow occurred, at least one DMA transfer is still running at the End Of Frame. This flag is reset after a read operation.

Bit 1 – ERROR Transfer Error Detected

Value	Description
0	No system bus error has been detected since the last read of LCDC_BASEISR.
1	A system bus error has been detected. This flag is reset after a read operation.

Bit 0 – END End of Frame DMA Transfer

Value	Description
0	No end of frame DMA transfer has been detected since last read of LCDC_BASEISR.
1	End of transfer has been detected. This flag is reset after a read operation.

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
				DISCEN			REP	DMA
Access				R/W			R/W	R/W
Reset				0			0	0

Bit 4 – DISCEN Discard Area Enable

Value	Description
0	The whole frame is retrieved from memory.
1	The DMA channel discards the area located at screen coordinates {DISCXPOS, DISCYPOS}.

Bit 1 – REP Use Replication Logic to Expand RGB Color to 24 Bits
Alpha component is also affected by the replication logic.
In all ARGB formats with one transparency bit, REP affects the A field interpretation when A=1. If REP=0, then A=1 will be interpreted as Alpha = 0x80 (half transparent). If REP=1, then A=1 will be interpreted as Alpha = 0xFF (full opaque)

Value	Description
0	When the selected pixel depth is less than 24 bpp, the pixel is shifted and LSBs are set to 0.
1	When the selected pixel depth is less than 24 bpp, the pixel is shifted and the LSB replicates the MSB.

Bit 0 – DMA Use DMA Data Path

Value	Description
0	The default color is used on the base layer.
1	The DMA channel retrieves the pixel stream from the memory.

Bits 26:16 – DISCYSIZE[10:0] Discard Area Vertical Size
Discard vertical size in pixels. The discard size is set to (DISCYSIZE + 1) pixels vertically.

Bits 10:0 – DISCXSIZE[10:0] Discard Area Horizontal Size
Discard horizontal size in pixels. The discard size is set to (DISCXSIZE + 1) pixels horizontally.

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:24 – WPKEY[7:0] Write Protection Key Password

Value	Name	Description
0x58	PASSWD	Writing any other value in this field aborts the write operation of the WPCFGE, WPITE, WPCRE bits. Always reads as 0.

Bit 14 – HEWPCRE High-End Overlay Write Protection Control Registers Enable

Value	Description
0	Disables the write protection of High-End Overlay Control registers if WPKEY corresponds to 0x58 (“X” in ASCII).
1	Enables the write protection of High-End Overlay Control registers if WPKEY corresponds to 0x58 (“X” in ASCII).

Bit 13 – HEWPITE High-End Overlay Write Protection Interrupt Registers Enable

Value	Description
0	Disables the write protection of High-End Overlay Interrupt Enable/Disable registers if WPKEY corresponds to 0x58 (“X” in ASCII).
1	Enables the write protection of High-End Overlay Interrupt Enable/Disable registers if WPKEY corresponds to 0x58 (“X” in ASCII).

Bit 12 – HEWPCFGE High-End Overlay Write Protection Configuration Registers Enable

Value	Description
0	Disables the write protection of High-End Overlay Configuration registers if WPKEY corresponds to 0x58 (“X” in ASCII).
1	Enables the write protection of High-End Overlay Configuration registers if WPKEY corresponds to 0x58 (“X” in ASCII).

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 11 – O2WPCRE Overlay 2 Write Protection Control Registers Enable

Value	Description
0	Disables the write protection of Overlay 2 Control registers if WPKEY corresponds to 0x58 (“X” in ASCII).
1	Enables the write protection of Overlay 2 Control registers if WPKEY corresponds to 0x58 (“X” in ASCII).

Bit 10 – O2WPITE Overlay 2 Write Protection Interrupt Registers Enable

Value	Description
0	Disables the write protection of Overlay 2 Interrupt Enable/Disable registers if WPKEY corresponds to 0x58 (“X” in ASCII).
1	Enables the write protection of Overlay 2 Interrupt Enable/Disable registers if WPKEY corresponds to 0x58 (“X” in ASCII).

Bit 9 – O2WPCFGE Overlay 2 Write Protection Configuration Registers Enable

Value	Description
0	Disables the write protection of Overlay 2 Configuration registers if WPKEY corresponds to 0x58 (“X” in ASCII).
1	Enables the write protection of Overlay 2 Configuration registers if WPKEY corresponds to 0x58 (“X” in ASCII).

Bit 8 – O1WPCRE Overlay 1 Write Protection Control Registers Enable

Value	Description
0	Disables the write protection of Overlay 1 Control registers if WPKEY corresponds to 0x58 (“X” in ASCII).
1	Enables the write protection of Overlay 1 Control registers if WPKEY corresponds to 0x58 (“X” in ASCII).

Bit 7 – O1WPITE Overlay 1 Write Protection Interrupt Registers Enable

Value	Description
0	Disables the write protection of Overlay 1 Interrupt Enable/Disable registers if WPKEY corresponds to 0x58 (“X” in ASCII).
1	Enables the write protection of Overlay 1 Interrupt Enable/Disable registers if WPKEY corresponds to 0x58 (“X” in ASCII).

Bit 6 – O1WPCFGE Overlay 1 Write Protection Configuration Registers Enable

Value	Description
0	Disables the write protection of Overlay 1 Configuration registers if WPKEY corresponds to 0x58 (“X” in ASCII).
1	Enables the write protection of Overlay 1 Configuration registers if WPKEY corresponds to 0x58 (“X” in ASCII).

Bit 5 – BWPCRE Base Layer Write Protection Control Registers Enable

Value	Description
0	Disables the write protection of base layer Control registers if WPKEY corresponds to 0x58 (“X” in ASCII).
1	Enables the write protection of base layer Control registers if WPKEY corresponds to 0x58 (“X” in ASCII).

Bit 4 – BWPITE Base Layer Write Protection Interrupt Registers Enable

Value	Description
0	Disables the write protection of base layer Interrupt Enable/Disable registers if WPKEY corresponds to 0x58 (“X” in ASCII).
1	Enables the write protection of base layer Interrupt Enable/Disable registers if WPKEY corresponds to 0x58 (“X” in ASCII).

Bit 3 – BWPCFGE Base Layer Write Protection Configuration Registers Enable

Value	Description
0	Disables the write protection of base layer Configuration registers if WPKEY corresponds to 0x58 (“X” in ASCII).
1	Enables the write protection of base layer Configuration registers if WPKEY corresponds to 0x58 (“X” in ASCII).

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 2 – WPCRE Write Protection Control Registers Enable

Value	Description
0	Disables the write protection of LCDC Control registers if WPKEY corresponds to 0x58 (“X” in ASCII).
1	Enables the write protection of LCDC Control registers if WPKEY corresponds to 0x58 (“X” in ASCII).

Bit 1 – WPITE Write Protection Interrupt Registers Enable

Value	Description
0	Disables the write protection of LCDC Interrupt Enable/Disable registers if WPKEY corresponds to 0x58 (“X” in ASCII).
1	Enables the write protection of LCDC Interrupt Enable/Disable registers if WPKEY corresponds to 0x58 (“X” in ASCII).

Bit 0 – WPCFGE Write Protection Configuration Registers Enable

Value	Description
0	Disables the write protection of LCDC Configuration registers if WPKEY corresponds to 0x58 (“X” in ASCII).
1	Enables the write protection of LCDC Configuration registers if WPKEY corresponds to 0x58 (“X” in ASCII).

46.7.34. LCDC Write Protection Status Register

Name: LCDC_WPSR
Offset: 0x000000E8
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	WPVSRC[15:8]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	WPVSRC[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
						SEQE	CGD	WPVS
Access						R	R	R
Reset						0	0	0

Bits 23:8 – WPVSRC[15:0] Write Protection Violation Source
When WPVS = 1, WPVSRC indicates the register address offset at which a write access has been attempted.

Bit 2 – SEQE Internal Sequencer Error (cleared on read)

Value	Name
0	No peripheral internal sequencer error has occurred since the last read of LCDC_WPSR.
1	A peripheral internal sequencer error has occurred since the last read of LCDC_WPSR. This flag can only be set under abnormal operating conditions.

Bit 1 – CGD Clock Glitch Detected (cleared on read)

Value	Description
0	The clock monitoring circuitry has not been corrupted since the last read of LCDC_WPSR. Under normal operating conditions, this bit is always cleared.
1	The clock monitoring circuitry has been corrupted since the last read of LCDC_WPSR. This flag can only be set in case of an abnormal clock signal waveform (glitch).

Bit 0 – WPVS Write Protection Violation Status

Value	Name
0	No write protection violation occurred since the last read of LCDC_WPSR.
1	A write protection violation has occurred since the last read of LCDC_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSRC.

46.7.35. Overlay 1 Interrupt Enable Register

Name: LCDC_OVR1IER
Offset: 0x00000160
Reset: –
Property: Write-only

This register can only be written if O1WPITE is cleared in the LCDC Write Protection Mode Register.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						OVF	ERROR	END
Access						W	W	W
Reset						–	–	–

Bit 2 – OVF Overflow Interrupt Enable

Bit 1 – ERROR Transfer Error Detected Interrupt Enable

Bit 0 – END End of Frame DMA Transfer Interrupt Enable

© 2026 Microchip Technology Inc. and its subsidiaries

46.7.36. Overlay 1 Interrupt Disable Register

Name: LCDC_OVR1IDR
Offset: 0x00000164
Reset: –
Property: Write-only

This register can only be written if O1WPITE is cleared in the LCDC Write Protection Mode Register

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						OVF	ERROR	END
Access						W	W	W
Reset						–	–	–

Bit 2 – OVF Overflow Interrupt Disable

Bit 1 – ERROR Error Interrupt Disable

Bit 0 – END End of Frame DMA Transfer Interrupt Disable

© 2026 Microchip Technology Inc. and its subsidiaries

46.7.37. Overlay 1 Interrupt Mask Register

Name: LCDC_OVR1IMR
Offset: 0x00000168
Reset: 0x00000000
Property: Read-only

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is disabled.

1: The corresponding interrupt is enabled.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						OVF	ERROR	END
Access						R	R	R
Reset						0	0	0

Bit 2 – OVF Overflow Interrupt Mask

Bit 1 – ERROR Bus Error Detected Interrupt Mask

Bit 0 – END End of Frame DMA Transfer Interrupt Mask

© 2026 Microchip Technology Inc. and its subsidiaries

46.7.38. Overlay 1 Interrupt Status Register

Name: LCDC_OVR1ISR
Offset: 0x0000016C
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						OVF	ERROR	END
Access						R	R	R
Reset						0	0	0

Bit 2 – OVF Overflow Detected

Value	Description
0	No overflow occurred since last read of LCDC_OVR1ISR.
1	An overflow occurred, at least one DMA transfer is still running at the End Of Frame. This flag is reset after a read operation

Bit 1 – ERROR Bus Error Detected

Value	Description
0	No system bus error has been detected since the last read of LCDC_OVR1ISR.
1	A system bus error has been detected. This flag is reset after a read operation

Bit 0 – END End of Frame DMA Transfer

Value	Description
0	No end of transfer has been detected since last read of LCDC_OVR1ISR.
1	End of transfer has been detected. This flag is reset after a read operation.

46.7.39. Overlay 1 Enable Register

Name: LCDC_OVR1EN
Offset: 0x00000170
Reset: 0x00000000
Property: Read/Write

This register can only be written if O1WPCRE is cleared in the LCDC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
Access								R/W
Reset								0

Bit 0 – ENABLE Layer Enable

Value	Description
0	The layer is disabled.
1	The layer is enabled.

© 2026 Microchip Technology Inc. and its subsidiaries

46.7.40. Overlay 1 Color Look-Up Table Address Register

Name: LCDC_OVR1CLA
Offset: 0x00000174
Reset: 0x00000000
Property: Read/Write

This register can only be written if O1WPCFGE is cleared in the LCDC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
	CLA[29:22]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
		BLEN[2:0]						
Access		R/W	R/W	R/W				
Reset		0	0	0				

Bits 6:4 – BLEN[2:0] System Bus Burst Length

Value	Name	Description
0	INCR1	System bus access is started as soon as there is enough space in the FIFO to store one data.
1	INCR4	System bus access is started as soon as there is enough space in the FIFO to store a total amount of 4 data. A system bus INCR4 Burst is used by default. INCR1 is used for bursts less than 4.
2	INCR8	System bus access is started as soon as there is enough space in the FIFO to store a total amount of 8 data. A system bus INCR8 Burst is used by default. INCR4 bursts are used for burst of 4 beats. INCR1 is used for bursts less than 4.
3	INCR16	System bus access is started as soon as there is enough space in the FIFO to store a total amount of 16 data. A system bus INCR16 Burst is used by default. INCR8 and INCR4 bursts are respectively used for burst of 8 and 4 beats. INCR1 is used for bursts less than 4.
4	INCR32	System bus access is started as soon as there is enough space in the FIFO to store a total amount of 32 data. A system bus INCR32 Burst is used by default. INCR16, INCR8 and INCR4 bursts are respectively used for burst of 16, 8 and 4 beats. INCR1 is used for bursts less than 4.
5-7	–	RESERVED

Bit 2 – GAM Gamma Correction

When GAM = 1, writing in LCDC_OVR1CLUT[0..255] has no effect.

Value	Description
0	Gamma correction is disabled
1	Gamma correction is enabled

Bit 0 – CLUTEN CLUT Mode Enable

When CLUTEN = 1, writing in LCDC_OVR1CLUT[0..255] has no effect.

Value	Description
0	RGB mode is selected.
1	CLUT mode is selected.

© 2026 Microchip Technology Inc. and its subsidiaries

46.7.44. Overlay 1 Configuration Register 2

Name: LCDC_OVR1CFG2
Offset: 0x00000184
Reset: 0x00000000
Property: Read/Write

This register can only be written if O1WPCFGE is cleared in the LCDC Write Protection Mode Register.

Bits 31:24 – A1[7:0] Alpha 1 Value
Operand used in the Alpha blending process depending on factor value.

Bits 23:16 – A0[7:0] Alpha 0 Value
Operand used in the Alpha blending process depending on factor value.

Bits 15:14 – DFACTA[1:0] Destination Factor for the Blending Equation of the Alpha Component

Value	Name	Description
0	ZERO	Sets the factor to 0.0.
1	ONE	Sets the factor to 1.0.
2	M_A0_MUL_AS	Computes A0 multiplied by source alpha, then sets the factor to one minus the result.
3	A1	Sets the factor to A1/255.

Bits 13:11 – DFACTC[2:0] Destination Factor for the Blending Equation of the Color Component

Value	Name	Description
0	ZERO	Sets the factor to 0.0.
1	ONE	Sets the factor to 1.0.
2	A0	Sets the factor to A0/255.
3	A1	Sets the factor to A1/255.
4	A0_MULT_AD	Sets the factor to A0 multiplied by Destination Alpha.
5	M_A0_MULT_AD	Sets the factor to A0 multiplied by Destination Alpha, then sets the factor to one minus the result.
6	M_A0_MUL_AS	Computes A0 multiplied by source alpha0, then sets the factor to one minus the result.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
7	M_A0	Computes one minus A0, then sets the factor to one minus the result.

Bits 10:9 – SFACTA[1:0] Source Factor for the Blending Equation of the Alpha Component

Value	Name	Description
0	ZERO	Sets the factor to 0.0.
1	ONE	Sets the factor to 1.0.
2	A0	Sets the factor to A0/255.
3	A1	Sets the factor to A1/255.

Bits 8:6 – SFACTC[2:0] Source Factor for the Blending Equation of the Color Component

Value	Name	Description
0	ONE	Sets the factor to 1.0.
1	ZERO	Sets the factor to 0.0.
2	A0	Sets the factor to A0/255.
3	A0_MULT_AD	Sets the factor to A0 multiplied by Destination Alpha.
4	A0_MUL_AS	Sets the factor to A0 multiplied by Source Alpha.
5	M_A0_MUL_AD	Computes A0 multiplied by Destination Alpha, then sets the factor to minus the result .

Bit 3 – DSTKEY Destination Color Keying

Value	Description
0	When CRKEY is enabled, color key is applied on OVR1 pixels, before the blending operation.
1	When CRKEY is enabled, color key is applied on OVR1 pixels, after the blending operation.

Bit 2 – CRKEY Chroma Keying Enable

Bit 1 – REP Replication Logic

The alpha component is also affected by the replication logic.
In all ARGB formats with one transparency bit, the REP configuration affects the A field interpretation when A=1. If REP=0, then A=1 is interpreted as Alpha = 0x80 (half transparent). If REP=1, then A=1 is interpreted as Alpha = 0xFF (full opaque).

Value	Description
0	When the selected pixel depth is less than 24 bpp, the pixel is shifted and LSBs are set to 0.
1	When the selected pixel depth is less than 24 bpp, the pixel is shifted and the LSB replicates the MSB.

Bit 0 – DMA DMA Enable

Value	Description
0	The pixel for the current layer is retrieved from the default color register.
1	The pixel stream is retrieved from the memory.

Reset						0	0	0

Bit 2 – OVF Overflow Detected

Value	Description
0	No overflow occurred since last read of LCDC_OVR2ISR.
1	An overflow occurred, at least one DMA transfer is still running at the End Of Frame. This flag is reset after a read operation.

Bit 1 – ERROR Bus Error Detected

Value	Description
0	No system bus error has been detected since the last read of LCDC_OVR2ISR.
1	A system bus error has been detected. This flag is reset after a read operation.

Bit 0 – END End of Frame DMA Transfer

Value	Description
0	No end of transfer has been detected since last read of LCDC_OVR2ISR.
1	End of transfer has been detected. This flag is reset after a read operation.

Bit 2 – GAM Gamma Correction

When GAM = 1, writing in LCDC_OVR2CLUT[0..255] has no effect.

Value	Description
0	Gamma correction is disabled
1	Gamma correction is enabled

Bit 0 – CLUTEN CLUT Mode Enable

When CLUTEN = 1, writing in LCDC_OVR2CLUT[0..255] has no effect.

Value	Description
0	RGB mode is selected.
1	CLUT mode is selected.

Reset	0	0	0	0	0	0	0	0

Bits 31:24 – ADEF[7:0] Alpha Default
Default Alpha value when the Overlay 2 DMA channel is disabled (only for post-processing usage).

Bits 23:16 – RDEF[7:0] Red Default
Default red color when the Overlay 2 DMA channel is disabled.

Bits 15:8 – GDEF[7:0] Green Default
Default green color when the Overlay 2 DMA channel is disabled.

Bits 7:0 – BDEF[7:0] Blue Default
Default blue color when the Overlay 2 DMA channel is disabled.

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 23:16 – RKEY[7:0] Red Color Component Chroma Key
Reference red chroma key used to match the red color of the current overlay.

Bits 15:8 – GKEY[7:0] Green Color Component Chroma Key
Reference green chroma key used to match the green color of the current overlay.

Bits 7:0 – BKEY[7:0] Blue Color Component Chroma Key
Reference blue chroma key used to match the blue color of the current overlay.

© 2026 Microchip Technology Inc. and its subsidiaries

46.7.67. Overlay 2 Configuration Register 8

Name: LCDC_OVR2CFG8
Offset: 0x0000029C
Reset: 0x00000000
Property: Read/Write

This register can only be written if O2WPCFGE is cleared in the LCDC Write Protection Mode Register.

Image components are MSB-aligned with their respective MASK field, so that if selected input mode involves components less than 8 bits, MASK field LSBs are ignored.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8
	DFACTA[1:0]		DFACTC[2:0]			SFACTA[1:0]		SFACTC[2]
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	SFACTC[1:0]				DSTKEY	CRKEY	REP	DMA
Access	R/W	R/W			R/W	R/W	R/W	R/W
Reset	0	0			0	0	0	0

Bits 31:24 – A1[7:0] Alpha 1 Value
Operand used in Alpha blending process depending on the factor value.

Bits 23:16 – A0[7:0] Alpha 0 Value
Operand used in Alpha blending process depending on the factor value.

Bits 15:14 – DFACTA[1:0] Destination Factor for the Blending Equation of the Alpha Component

Value	Name	Description
0	ZERO	Sets the factor to 0.0.
1	ONE	Sets the factor to 1.0.
2	M_A0_MUL_AS	Computes A0 multiplied by source alpha, then sets the factor to one minus the result.
3	A1	Sets the factor to A1/255.

Bits 13:11 – DFACTC[2:0] Destination Factor for the Blending Equation of the Color Component

Value	Name	Description
0	ZERO	Sets the factor to 0.0.
1	ONE	Sets the factor to 1.0.
2	A0	Sets the factor to A0/255.
3	A1	Sets the factor to A1/255.
4	A0_MULT_AD	Sets the factor to A0 multiplied by Destination Alpha.
5	M_A0_MULT_AD	Sets the factor to A0 multiplied by Destination Alpha, then set the factor one minus the result.
6	M_A0_MUL_AS	Computes A0 multiplied by source alpha0, then sets the factor to one minus the result.
7	M_A0	Computes one minus A0, then sets the factor to one minus the result.

© 2026 Microchip Technology Inc. and its subsidiaries

Bits 10:9 – SFACTA[1:0] Source Factor for the Blending Equation of the Alpha Component

Value	Name	Description
0	ZERO	Sets the factor to 0.0.
1	ONE	Sets the factor to 1.0.
2	A0	Sets the factor to A0/255.
3	A1	Sets the factor to A1/255.

Bits 8:6 – SFACTC[2:0] Source Factor for the Blending Equation of the Color Component

Value	Name	Description
0	ONE	Sets the factor to 1.0.
1	ZERO	Sets the factor to 0.0.
2	A0	Sets the factor to A0/255.
3	A0_MULT_AD	Sets the factor to A0 multiplied by Destination Alpha.
4	A0_MUL_AS	Sets the factor to A0 multiplied by Source Alpha.
5	M_A0_MUL_AD	Computes A0 multiplied by Destination Alpha, then sets the factor to minus the result.

Bit 3 – DSTKEY Destination Color Keying

Value	Description
0	When CRKEY is enabled, color key is applied on OVR2 pixels, before the blending operation.
1	When CRKEY is enabled, color key is applied on OVR2 pixels, after the blending operation.

Bit 2 – CRKEY Chroma Keying

Bit 1 – REP Replication Logic

Alpha component is also affected by the replication logic.
In all ARGB formats with 1 transparency bit, REP configuration affects the A field interpretation when A=1. If REP=0, then A=1 will be interpreted as a Alpha = 0x80 (half transparent). If REP=1, then A=1 will be interpreted as a Alpha = 0xFF (full opaque).

Value	Description
0	When the selected pixel depth is less than 24 bpp, the pixel is shifted and LSBs are set to 0.
1	When the selected pixel depth is less than 24 bpp, the pixel is shifted and the LSB replicates the MSB.

Bit 0 – DMA DMA Enable

Value	Description
0	The pixel for the current layer is retrieved from the default color register.
1	The pixel stream is retrieved from the memory.

Bit 18 – CROVF Overflow Detected for Cr plane

Value	Description
0	No overflow occurred since last read of LCDC_HEOISR.
1	An overflow occurred, at least one DMA transfer is still running at the End Of Frame. This flag is reset after a read operation.

Bit 17 – CRERROR Bus Transfer Error detected for Cr plane

Value	Description
0	No system bus error has been detected since the last read of LCDC_HEOISR.
1	A system bus error has been detected. This flag is reset after a read operation.

Bit 16 – CREND End of Frame DMA Transfer for Cr plane

Value	Description
0	No end of transfer has been detected since last read of LCDC_HEOISR.
1	End of transfer has been detected. This flag is reset after a read operation.

Bit 10 – CBOVF Overflow Detected for Cb or CbCr plane

Value	Description
0	No overflow occurred since last read of LCDC_HEOISR.
1	An overflow occurred, at least one DMA transfer is still running at the End Of Frame. This flag is reset after a read operation.

Bit 9 – CBERROR Bus Transfer Error Detected for Cb or CbCr plane

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	No system bus error has been detected since the last read of LCDC_HEOISR.
1	A system bus error has been detected. This flag is reset after a read operation.

Bit 8 – CBEND End of Frame DMA Transfer for Cb or CbCr plane

Value	Description
0	No end of transfer has been detected since last read of LCDC_HEOISR.
1	End of transfer has been detected. This flag is reset after a read operation.

Bit 2 – OVF Overflow Detected

Value	Description
0	No overflow occurred since last read of LCDC_HEOISR.
1	An overflow occurred, at least one DMA transfer is still running at the End Of Frame. This flag is reset after a read operation

Bit 1 – ERROR Bus Error Detected

Value	Description
0	No system bus error has been detected since the last read of LCDC_HEOISR.
1	A system bus error has been detected. This flag is reset after a read operation.

Bit 0 – END End of Frame DMA Transfer

Value	Description
0	No end of transfer has been detected since last read of LCDC_HEOISR.
1	End of transfer has been detected. This flag is reset after a read operation.

46.7.81. High-End Overlay Configuration Register 0

Name: LCDC_HEOCFG0
Offset: 0x00000390
Reset: 0x00000000
Property: Read/Write

This register can only be written if HEWPCFGE is cleared in the LCDC Write Protection Mode Register.

Bits 10:8 – BLENCC[2:0] System Bus Burst Length for Cb-Cr Channel

Value	Name	Description
0	INCR1	System bus access is started as soon as there is enough space in the FIFO to store one data.
1	INCR4	System bus access is started as soon as there is enough space in the FIFO to store a total amount of 4 data. A system bus INCR4 Burst is used by default. INCR1 is used for bursts less than 4.
2	INCR8	System bus access is started as soon as there is enough space in the FIFO to store a total amount of 8 data. A system bus INCR8 Burst is used by default. INCR4 bursts are used for bursts of 4 beats. INCR1 is used for bursts less than 4.
3	INCR16	System bus access is started as soon as there is enough space in the FIFO to store a total amount of 16 data. A system bus INCR16 Burst is used by default. INCR8 and INCR4 bursts are respectively used for bursts of 8 and 4 beats. INCR1 is used for bursts less than 4.
4	INCR32	System bus access is started as soon as there is enough space in the FIFO to store a total amount of 32 data. A system bus INCR32 Burst is used by default. INCR16, INCR8 and INCR4 bursts are respectively used for bursts of 16, 8 and 4 beats. INCR1 is used for bursts less than 4.

Bits 6:4 – BLEN[2:0] System Bus Burst Length
This field is applicable only for YCrCb, planar or semi-planar modes.

Value	Name	Description
0	INCR1	System bus access is started as soon as there is enough space in the FIFO to store one data.
1	INCR4	System bus access is started as soon as there is enough space in the FIFO to store a total amount of 4 data. A system bus INCR4 Burst is used by default. INCR1 is used for bursts less than 4.
2	INCR8	System bus access is started as soon as there is enough space in the FIFO to store a total amount of 8 data. A system bus INCR8 Burst is used by default. INCR4 bursts are used for bursts of 4 beats. INCR1 is used for bursts less than 4.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
3	INCR16	System bus access is started as soon as there is enough space in the FIFO to store a total amount of 16 data. A system bus INCR16 Burst is used by default. INCR8 and INCR4 bursts are respectively used for bursts of 8 and 4 beats. INCR1 is used for bursts less than 4.
4	INCR32	System bus access is started as soon as there is enough space in the FIFO to store a total amount of 32 data. A system bus INCR32 Burst is used by default. INCR16, INCR8 and INCR4 bursts are respectively used for bursts of 16, 8 and 4 beats. INCR1 is used for bursts less than 4.

46.7.82. High-End Overlay Configuration Register 1

Name: LCDC_HEOCFG1
Offset: 0x00000394
Reset: 0x00000000
Property: Read/Write

This register can only be written if HEWPCFGE is cleared in the LCDC Write Protection Mode Register.

Bit	31	30	29	28	27	26	25	24
								ILD
Access								R/W
Reset								0

Bit	23	22	21	20	19	18	17	16
								YCC422ROT
Access								R/W
Reset								0

Bit	15	14	13	12	11	10	9	8
	YCCMODE[3:0]						CLUTMODE[1:0]	
Access	R/W	R/W	R/W	R/W			R/W	R/W
Reset	0	0	0	0			0	0

Bit	7	6	5	4	3	2	1	0
	RGBMODE[3:0]					GAM	YCCEN	CLUTEN
Access	R/W	R/W	R/W	R/W		R/W	R/W	R/W
Reset	0	0	0	0		0	0	0

Bit 24 – ILD Interlaced Content

Value	Description
0	Progressive scan is used.
1	Interlaced Frame content is used and deinterlacing process is activated.

Bit 16 – YCC422ROT YCbCr 4:2:2 Rotation

Value	Description
0	Chroma upsampling kernel is configured to use 0 and 180 degrees algorithm.
1	Indicates that the chroma upsampling kernel is configured to use the 4:2:2 rotation algorithm. This bit is relevant only when a rotation angle of 90 degrees or 270 degrees is used.

Bits 15:12 – YCCMODE[3:0] YCbCr Mode Input Selection

Value	Name	Description
0	32BPP_AYCBCR	32 bpp AYCbCr 444
1	16BPP_YCBCR_MODE0	16 bpp Cr(n)Y(n+1)Cb(n)Y(n) 4:2:2
2	16BPP_YCBCR_MODE1	16 bpp Y(n+1)Cr(n)Y(n)Cb(n) 4:2:2
3	16BPP_YCBCR_MODE2	16 bpp Cb(n)Y(+1)Cr(n)Y(n) 4:2:2
4	16BPP_YCBCR_MODE3	16 bpp Y(n+1)Cb(n)Y(n)Cr(n) 4:2:2
5	16BPP_YCBCR_SEMIPLANAR	16 bpp Semiplanar 4:2:2 YCbCr
6	16BPP_YCBCR_PLANAR	16 bpp Planar 4:2:2 YCbCr
7	12BPP_YCBCR_SEMIPLANAR	12 bpp Semiplanar 4:2:0 YCbCr
8	12BPP_YCBCR_PLANAR	12 bpp Planar 4:2:0 YCbCr

Bits 9:8 – CLUTMODE[1:0] CLUT Mode Input Selection

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
0	CLUT_1BPP	CLUT mode set to 1 bit per pixel
1	CLUT_2BPP	CLUT mode set to 2 bits per pixel
2	CLUT_4BPP	CLUT mode set to 4 bits per pixel
3	CLUT_8BPP	CLUT mode set to 8 bits per pixel

Bits 7:4 – RGBMODE[3:0] RGB Mode Input Selection

Value	Name	Description
0	12BPP_RGB_444	12 bpp RGB 444
1	16BPP_ARGB_4444	16 bpp ARGB 4444
2	16BPP_RGBA_4444	16 bpp RGBA 4444
3	16BPP_RGB_565	16 bpp RGB 565
4	16BPP_ARGB_1555	16 bpp ARGB 1555
5	18BPP_RGB_666	18 bpp RGB 666
6	18BPP_RGB_666PACKED	18 bpp RGB 666 PACKED
7	19BPP_ARGB_1666	19 bpp ARGB 1666
8	19BPP_ARGB_PACKED	19 bpp ARGB 1666 PACKED
9	24BPP_RGB_888	24 bpp RGB 888
10	24BPP_RGB_888_PACKED	24 bpp RGB 888 PACKED
11	25BPP_ARGB_1888	25 bpp ARGB 1888
12	32BPP_ARGB_8888	32 bpp ARGB 8888
13	32BPP_RGBA_8888	32 bpp RGBA 8888

Bit 2 – GAM Gamma Correction

When GAM = 1, writing in LCDC_HEOCLUT[0..255] has no effect.

Value	Description
0	Gamma correction is disabled.
1	Gamma correction is enabled.

Bit 1 – YCCEN YCbCr Color Space Enable

Value	Description
0	Color space is RGB.
1	Color space is YCbCr.

Bit 0 – CLUTEN CLUT Mode Enable

When CLUTEN = 1, writing in LCDC_HEOCLUT[0..255] has no effect.

Value	Description
0	RGB mode is selected.
1	CLUT mode is selected.

© 2026 Microchip Technology Inc. and its subsidiaries

46.7.83. High-End Overlay Configuration Register 2

Name: LCDC_HEOCFG2
Offset: 0x00000398
Reset: 0x00000000
Property: Read/Write

This register can only be written if HEWPCFGE is cleared in the LCDC Write Protection Mode Register.

Bits 31:24 – A1[7:0] Alpha 1 Value
Operand used in Alpha blending process depending on factor value.

Bits 23:16 – A0[7:0] Alpha 0 Value
Operand used in Alpha blending process depending on factor value.

Bits 15:14 – DFACTA[1:0] Destination Factor for the Blending Equation of the Alpha Component

Value	Name	Description
0	ZERO	Sets the factor to 0.0.
1	ONE	Sets the factor to 1.0.
2	M_A0_MUL_AS	Computes A0 multiplied by source alpha, then set the factor to one minus the result.
3	A1	Sets the factor to A1/255.

Bits 13:11 – DFACTC[2:0] Destination Factor for the Blending Equation of the Color Component

Value	Name	Description
0	ZERO	Sets the factor to 0.0.
1	ONE	Sets the factor to 1.0.
2	A0	Sets the factor to A0/255.
3	A1	Sets the factor to A1/255.
4	A0_MULT_AD	Sets the factor to A0 multiplied by Destination Alpha.
5	M_A0_MULT_AD	Sets the factor to A0 multiplied by Destination Alpha, then sets the factor one minus the result.
6	M_A0_MUL_AS	Computes A0 multiplied by source alpha0, then set the factor to one minus the result.
7	M_A0	Computes one minus A0, then set the factor to one minus the result.

© 2026 Microchip Technology Inc. and its subsidiaries

Bits 10:9 – SFACTA[1:0] Source Factor for the Blending Equation of the Alpha Component

Value	Name	Description
0	ZERO	Sets the factor to 0.0.
1	ONE	Sets the factor to 1.0.
2	A0	Sets the factor to A0/255.
3	A1	Sets the factor to A1/255.

Bits 8:6 – SFACTC[2:0] Source Factor for the Blending Equation of the Color Component

Value	Name	Description
0	ONE	Sets the factor to 1.0.
1	ZERO	Sets the factor to 0.0.
2	A0	Sets the factor to A0/255.
3	A0_MULT_AD	Sets the factor to A0 multiplied by Destination Alpha.
4	A0_MUL_AS	Sets the factor to A0 multiplied by Source Alpha.
5	M_A0_MUL_AD	Computes A0 multiplied by Destination Alpha, then sets the factor to minus the result.

Bit 5 – VIDPRI Video Priority Mode

Value	Description
0	HEO is located below OVR1.
1	HEO is located above OVR1.

Bit 3 – DSTKEY Destination Color Keying

Value	Description
0	When CRKEY is enabled, color key is applied on HEO pixels, before blending operation.
1	When CRKEY is enabled, color key is applied on HEO pixels, after blending operation.

Bit 2 – CRKEY Chroma Keying

Bit 1 – REP Replication Logic

Alpha component is also affected by the replication logic.
In all ARGB formats with 1 transparency bit, the REP configuration affects the A field interpretation when A=1. If REP=0, then A=1 will be interpreted as Alpha = 0x80 (half transparent). If REP=1, then A=1 will be interpreted as Alpha = 0xFF (full opaque)

Value	Description
0	When the selected pixel depth is less than 24 bpp, the pixel is shifted and LSBs are set to 0.
1	When the selected pixel depth is less than 24 bpp, the pixel is shifted and the LSB replicates the MSB.

Bit 0 – DMA DMA Enable

Value	Description
0	The pixel for the current layer is retrieved from the default color register.
1	The pixel stream is retrieved from the memory.

Bit 4 – BL Black Level

Value	Description
0	Black level offset is disabled.
1	Black level offset is enabled.

Bit 0 – ENABLE Contrast, Brightness Hue and Saturation Enable

Value	Description
0	CBHS is disabled.
1	CBHS is enabled.

Bits 25:24 – VXSCCFG1[1:0] Vertical Scaler Chroma Configuration for Field 1(only used for YCrCb Interlaced Frame Content)

Filter taps shift for chroma components. The value is from 0 to 3 when VXSYTAP2 = 0 (4 coefficients used) and from 0 to 1 when when VXSYTAP2 = 1 (2 coefficients used).

Note: When using packed formats, VXSCCFG1 and VXSYCFG1 must have the same value.

Bit 22 – VXSCBICU Vertical Scaler Predefined Bicubic Taps Selected for Chroma/GB Component

Value	Description
0	Bicubic taps values are not selected.
1	Bicubic taps values are selected.

Bit 21 – VXSC1201N Vertical Scaler Bilinear 2 Taps Position among 4 Taps Filter for Chroma/GB Component

Value	Description
0	When selected, bilinear taps values are located on 0 and 1 positions (left aligned).
1	When selected, bilinear taps values are located on 0 and 1 positions (center aligned).

Bit 20 – VXSCTAP2 Vertical Scaler Predefined Bilinear 2 Taps Selected for Chroma/GB Component

Value	Description
0	Bilinear 2 taps value not selected.
1	Bilinear 2 taps value selected.

Bits 17:16 – VXSCCFG[1:0] Vertical Scaler Chroma/GB Configuration for Field 0 or Progressive Scan

Filter taps shift for chroma components. The value is from 0 to 3 when VXSYTAP2 = 0 (4 coefficients used) and from 0 to 1 when when VXSYTAP2 = 1 (2 coefficients used).

© 2026 Microchip Technology Inc. and its subsidiaries

Note: When using packed formats, VXSCCFG and VXSYCFG must have the same value.

Bits 9:8 – VXSYCFG1[1:0] Vertical Scaler Chroma/GB Configuration for Field 1 (only used for interlaced frame content)

Filter taps shift for chroma components. The value is from 0 to 3 when VXSYTAP2 = 0 (4 coefficients used) and from 0 to 1 when when VXSYTAP2 = 1 (2 coefficients used).

Note: When using packed formats, VXSYCFG1 and VXSCCFG1 must have the same value.

Bit 6 – VXSYBICU Vertical Scaler Predefined Bicubic Taps Selected for Luma/AR Component

Value	Description
0	Bicubic taps values are not selected.
1	Bicubic taps values are selected.

Bit 5 – VXSY1201N Vertical Scaler Bilinear 2 Taps Position among 4 Filter Taps for Luma/AR Component

Value	Description
0	When selected, bilinear tap values are located on 0 and 1 positions (left-aligned).
1	When selected, bilinear tap values are located on 0 and 1 positions (center-aligned).

Bit 4 – VXSYTAP2 Vertical Scaler Predefined Bilinear 2 Taps Selected for Luma/AR Component

Value	Description
0	Bilinear 2 taps value not selected.
1	Bilinear 2 taps value selected.

Bits 1:0 – VXSYCFG[1:0] Vertical Scaler Luma/AR Configuration for Field 0 or Progressive Scan

Filter taps shift for luma component. The value is from 0 to 3 when VXSYTAP2=0 (4 coefficients used) and from 0 to 1 when VXSYTAP2=1 (2 coefficients used).

Note: When using packed formats, VXSYCFG and VXSCCFG must have the same value.

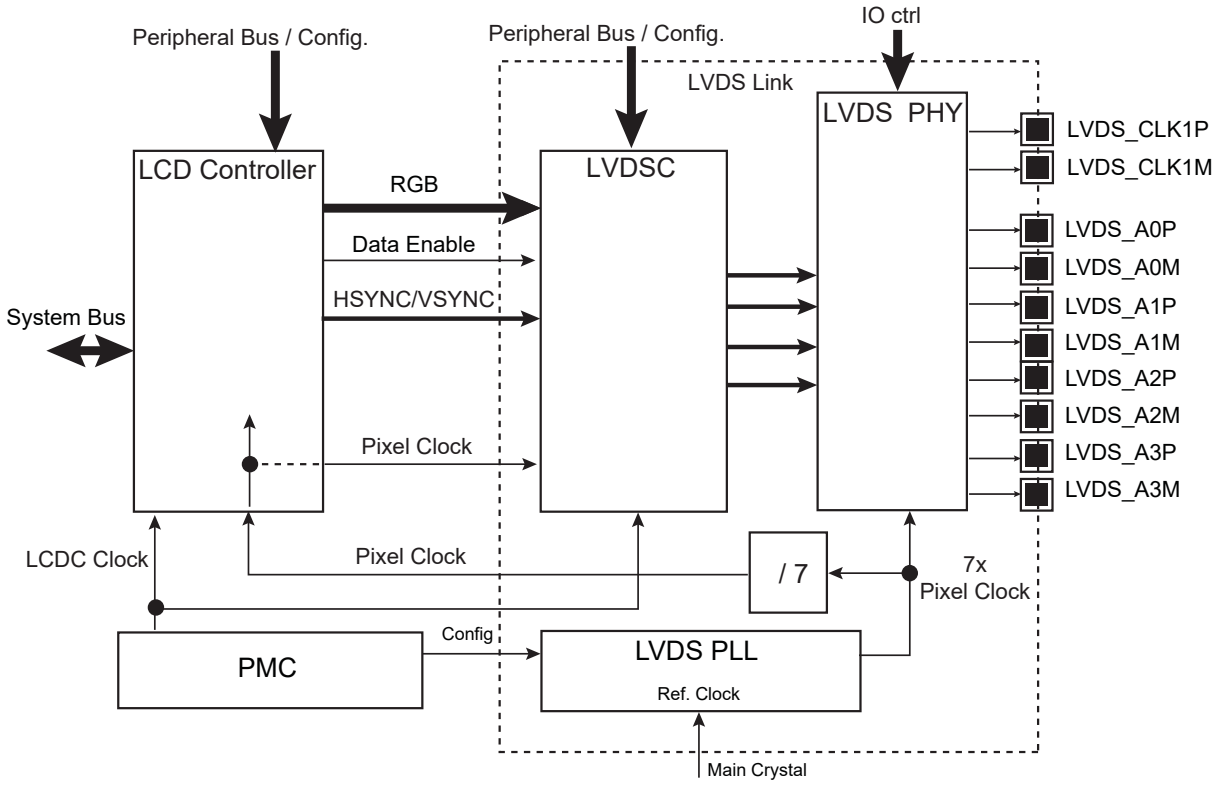
47. Low Voltage Differential Signaling Controller (LVDSC)

47.1. Description

The Low Voltage Differential Signaling Controller (LVDSC) manages data format conversion from the LCD Controller internal DPI bus to OpenLDI LVDS output signals.



LVDSC functions include bit mapping, balanced mode management, and serializer.

47.2. Embedded Characteristics

- 18-/24-bit DPI Input Format
- VESA/JEIDA Formats
- DC-balanced Mode Allowing AC-coupling LVDS Receivers
- Single Channel, 5 LVDS Lanes (4 Data Lanes + 1 Clock Lane)

47.3. Block Diagram

Figure 47.1. LVDSC Block Diagram

47.4. I/O Lines Description

Table 47.1. I/O Lines Description

Signal Name	Description	Type
LVDS_CLK1P	Differential LVDS clock line transceiver output	Output
LVDS_CLK1M		

© 2026 Microchip Technology Inc. and its subsidiaries

Table 47.1. I/O Lines Description (continued)

Signal Name	Description	Type
LVDS_A0P	Differential LVDS data 0 line transceiver output	Output
LVDS_A0M		
LVDS_A1P	Differential LVDS data 1 line transceiver output	Output
LVDS_A1M		
LVDS_A2P	Differential LVDS data 2 line transceiver output	Output
LVDS_A2M		
LVDS_A3P	Differential LVDS data 3 line transceiver output	Output
LVDS_A3M		

47.5. Product Dependencies

47.5.1. I/O Lines

The LVDS outputs are multiplexed with digital functions on the I/O lines. If the LVDS interface is not used by the application (LVDSC_CR.SER_EN), the associated I/O lines can be used for other purposes (refer to section "Peripheral Signal Multiplexing on I/O Lines").

The I/O line LVDS_A3P/3N can be used by digital peripherals when the LVDSC is enabled and configured for 18-bit pixel data (LVDSC_CFGR.LCDC_PIXSIZE=1).

Note that if the LVDS interface is used, the I/O lines are associated to it automatically without any PIO configuration.

47.5.2. Power Management

The pixel clock is not continuously provided to the LVDSC. Before using the LVDSC, the programmer must first enable the LVDS-dedicated PLL and the LCDC peripheral clock in the Power Management Controller (PMC). Then the LCDC must be configured to generate the pixel clock.

Once the LVDS PLL is enabled, the pixel clock is used as the clock for LCDC, so its GCLK is no longer needed.

47.6. Functional Description

47.6.1. Introduction

The LVDSC is driven by the LCD Controller and drives the LVDS physical interface (LVDS PHY). The LVDSC embeds the bit mapping circuitry and configures the serializers located in the LVDS PHY.

The LCDC peripheral clock and pixel clock must be enabled to configure the LVDSC.

The operating modes of the LVDSC are configured in the Configuration register (LVDSC_CFGR). The configuration status bit CS in the Status register (LVDSC_SR) must be read at 0 prior to writing a new value in LVDSC_CFGR and in the User Control Bits register (LVDSC_UCBR).

When the configuration is complete, the LVDSC must be enabled by writing a ‘1’ to the bit SER_EN in the Control register (LVDSC_CR).

LVDSC_CFGR and LVDSC_UCBR cannot be modified when LVDSC_CR.SER_EN=1.

The reserved bit of the LVDS frame can be configured in LVDSC_UCBR.

47.6.2. Unbalanced Mode Mapping Format

The LVDS Link supports VESA (OpenLDI) and JEIDA formats.

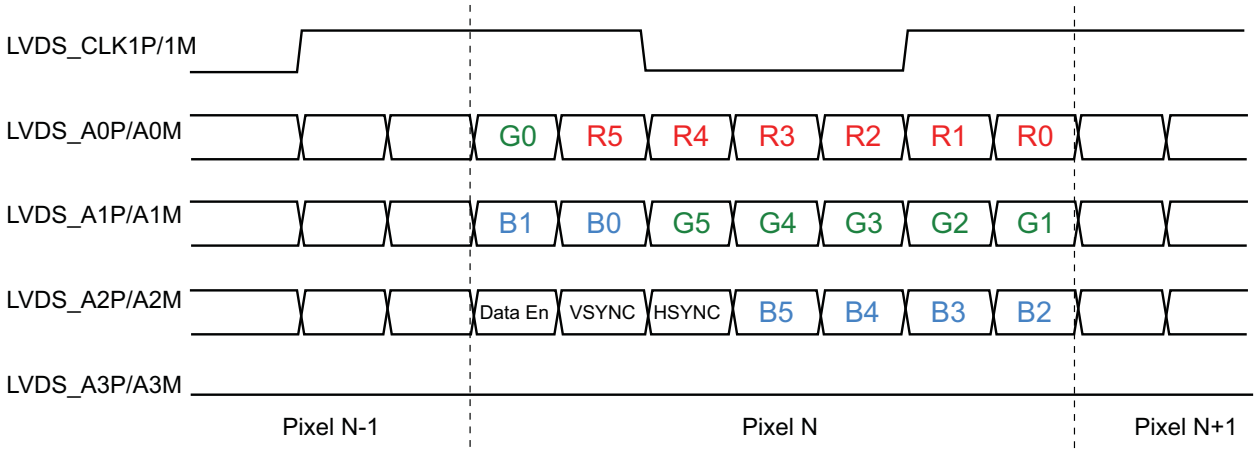
A2	Data en	VSYNC	HSYNC	B7	B6	B5	B4
A3	Reserved	B1	B0	G1	G0	R1	R0

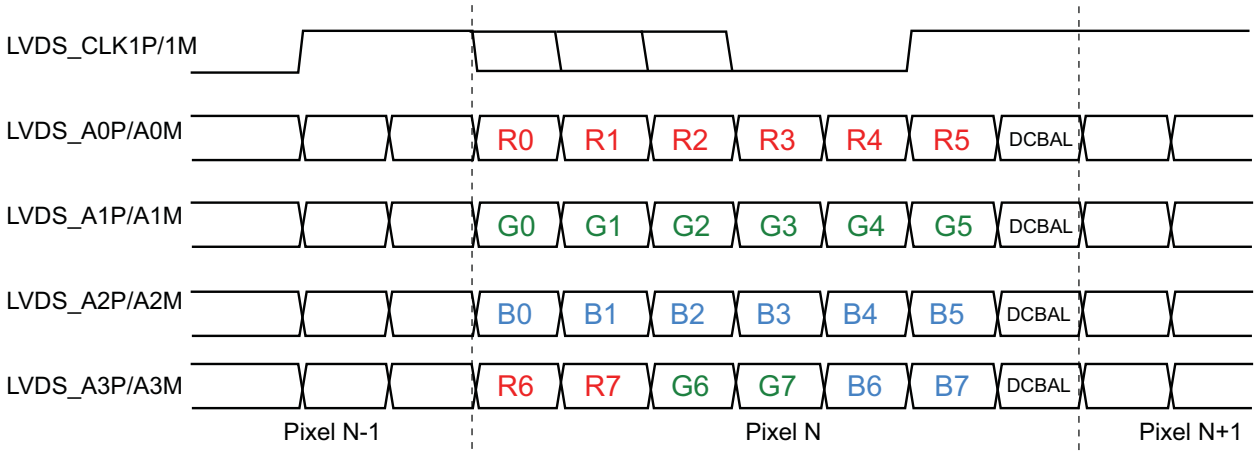
47.6.3. Supported Modes

LVDSC supports the following modes:



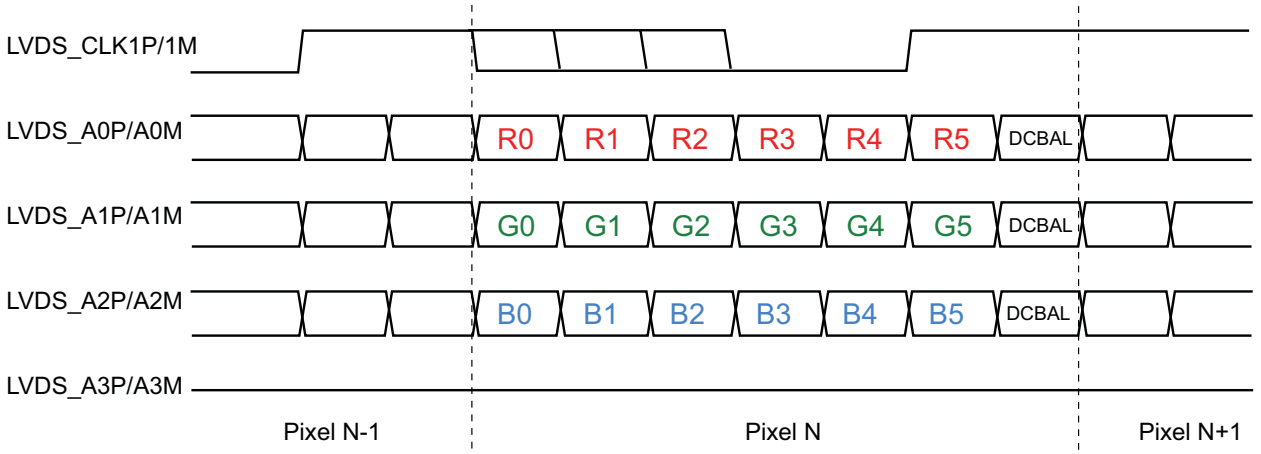
- 24-bit, Single Channel, DC-Unbalanced
- 18-bit, Single Channel, DC-Unbalanced
- 24-bit, Single Channel, DC-Balanced
- 18-bit, Single Channel, DC-Balanced

Figure 47.2. VESA Format, 24-bit, Single Channel, DC-Unbalanced



© 2026 Microchip Technology Inc. and its subsidiaries

Figure 47.3. VESA Format, 18-bit, Single Channel, DC-Unbalanced



The following figures illustrate balanced operating modes. In addition to pixel and control information, an additional bit, DCBAL, is transmitted on every signal line during each cycle. DCBAL bit minimizes the short- and long-term DC bias on the signal lines. The LVDSC sends the pixel data either unmodified or inverted. The value of the DCBAL bit is 0 when the data is sent unmodified and 1 when the data is sent inverted.

Figure 47.4. 24-bit, Single Channel, DC-Balanced

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 47.5. 18-bit, Single Channel, DC-Balanced

47.6.4. Register Write Protection

To prevent any single software error from corrupting LVDSC behavior, certain registers in the address space can be write-protected by setting the bit WPEN in the LVDSC Write Protection Status Register (LVDSC_WPMR).

The following registers are write-protected when LVDSC_WPMR.WPEN is set:

- LVDSC Control Register
- LVDSC Configuration Register
- LVDSC User Control Bits Register

To enhance safety, the write protection can be locked until the next system reset by configuring LCKWPEN=1 (WPEN must be 1 in the same access). When LCKWPEN=1, any further write access to the WPEN bit has no effect. If LCKWPEN=1 and WPEN=0, the lock is not activated.

Bits 25:24 – SWETYP[1:0] Software Error Type (cleared on read)

Value	Name	Description
1	WRITE_RO	The LVDSC is enabled and a write access has been performed on a read-only register.
2	UNDEF_RW	Access to an undefined address.
3	WEIRD_ACTION	Attempt to modify LVDSC_CFGR when LVDSC_CR.SER_EN=1.

Bits 15:8 – WPVSRC[7:0] Write Protection Violation Source
When WPVS=1, WPVSRC indicates the register address offset at which a write access has been attempted.

Bit 3 – SWE Software Control Error (cleared on read)

Value	Description
0	No software error has occurred since the last read of LVDSC_WPSR.
1	A software error has occurred since the last read of LVDSC_WPSR. The field SWETYP details the type of software error; the associated incorrect software access is reported in the field WPVSRC (if WPVS=0).

Bit 0 – WPVS Write Protection Violation Status (cleared on read)

Value	Description
0	No write protect violation has occurred since the last read of LVDSC_WPSR.
1	A write protect violation has occurred since the last read of LVDSC_WPSR. The address offset of the violated register is reported into field WPVSRC.

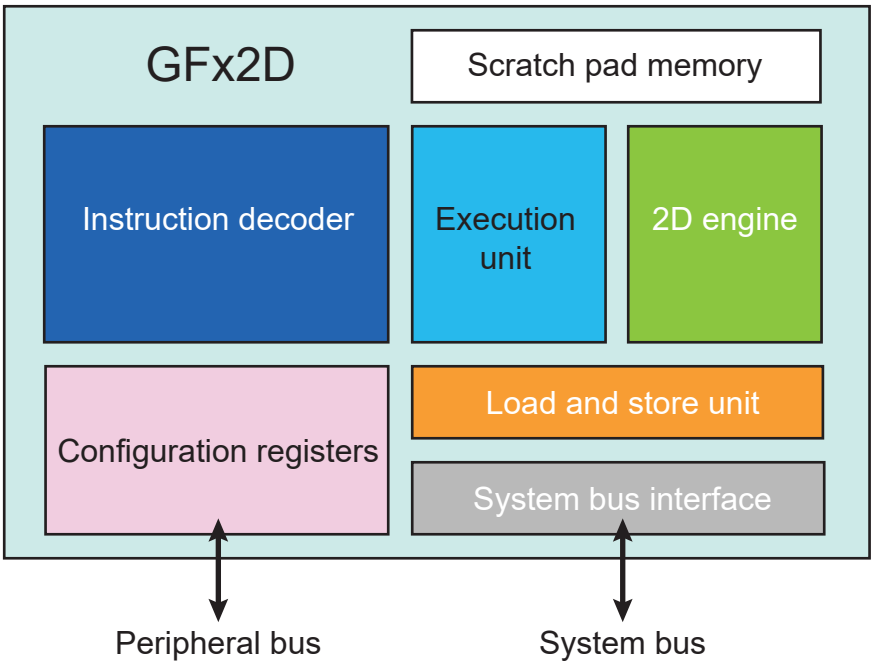
48. 2D Graphics Engine (GFX2D)

48.1. Description



The 2D Graphics Engine (GFX2D) is a drawing engine performing memory data move operations via its system bus host port.

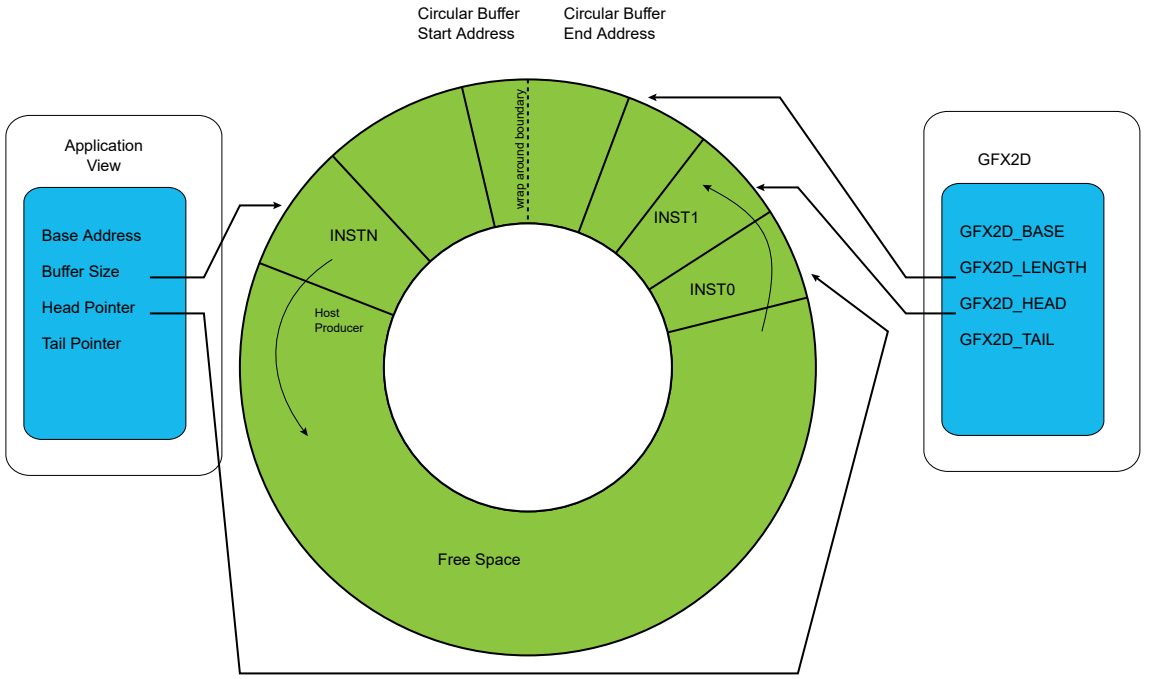
48.2. Embedded Characteristics

- 32-bit System Bus Host Interface
- Ring Buffer Command Interface
- FILL, COPY, BLEND and ROP Instructions
- Classic and Special Blending Functions Available
- Alpha Channel, Indexed Color and True Color Supported
- Linear-to-Cartesian Coordinate Transformation
- Automatic Transfer Regulation

48.3. Block Diagram

Figure 48.1. GFX2D Block Diagram

48.4. Functional Description



The GFX2D controller executes a sequence of instructions stored in a ring buffer located in the system memory. Once the instruction decoding is complete, the graphics engine executes the instruction, performs memory accesses and, optionally, raises an interrupt. A single instruction does not modify the whole set of internal registers. Host software must use a load register instruction to change the graphics context.

48.4.1. Ring Buffer Management

48.4.1.1. Ring Buffer Model Diagram

Figure 48.2. Ring Buffer Model

48.4.1.2. Ring Buffer Allocation

The instruction Ring Buffer (RB) is a contiguous memory area shared between the processor and the graphics engine. The size of the ring buffer is 24 x (GFX2D_LEN.LEN+1) bytes.

It is an efficient and effective means of passing instructions to the graphics. It is non-blocking and it facilitates batch processing of surfaces. The total RB length is software-programmable, and is a multiple of the RB memory allocation unit. A large RB is recommended to reduce CPU intervention.

Use the following software procedure to allocate a new ring buffer:

1. Wait for command completion by polling the GFX2D_GS.BUSY bit.
2. Disable the ring buffer by writing to GFX2D_GD.DISABLE.
3. Initialize the tail and head pointers by setting GFX2D_HEAD.HEAD and GFX2D_TAIL.TAIL to ‘0’.
4. Program the ring buffer base address by setting GFX2D_BASE.BASE to the base address. The address must be 24 bytes aligned.
5. Program the ring buffer length by setting GFX2D_LEN.LEN to the length.
6. Enable the ring buffer by writing to GFX2D_GE.ENABLE.

48.4.1.3. Ring Buffer Push-Pull Model

The Ring Buffer uses the producer/consumer model. The processor pushes the required instructions to render frames into the RB. The graphics consume the instructions and inform the processor that these free slots can be recycled. The RB is full when the number of free slots is equal to one. When the tail pointer is equal to the read pointer, the RB is empty. A new instruction can be pushed only if there is enough space available to store the whole instruction. When the memory is updated with one or more instructions, the head pointer is incremented with the total number of words of the batch of instructions. If the end of the RB is reached, the head pointer wraps around.

Use the following software procedure to add a command to the ring buffer queue:

© 2026 Microchip Technology Inc. and its subsidiaries

1. Monitor the Ring Buffer status from the Graphics side by reading the GFX2D_TAIL register. This register is updated by the hardware when the instruction has been successfully read from the memory.
2. Verify that there is enough space left in the buffer to insert the command. The queue is full when you have inserted N-1 instructions, where N is the number of entries.
3. Write the instruction at the memory location defined by GFX2D_BASE + GFX2D_HEAD.HEAD*4.
4. Increment the local head pointer and the GFX2D_HEAD.HEAD register to inform the graphics that new instructions have been added to the queue.
5. Wait for command completion by polling the BUSY bit in the GFX2D_GS register or wait for an interrupt if programmed.

48.4.1.4.Ring Buffer Disable

Use the following software procedure to halt the GFX2D:

1. Wait for command completion by polling the GFX2D_GS.BUSY bit.
2. Disable the ring buffer by writing '1' to GFX2D_GD.DISABLE.
3. Reset the tail and head pointers by writing '0' to GFX2D_HEAD.HEAD and GFX2D_TAIL.TAIL.

48.4.2.3. Color Look-Up Table (CLUT)

The GFX2D module includes two CLUTs. Each CLUT includes 256 entries containing 32 bits. Each entry contains a 32-bpp ARGB color.

Table 48.25. Color Look-Up Table Entry

Mem. addr.	0x3								0x2								0x1								0x0							
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Color entry	A								R								G								B							

The CLUT can be loaded using an LDR instruction with the LDRC bit set. The LDRCID bit indicates the targeted CLUT. The LDRCS bit provides the amount of data to be loaded. Using a reduced CLUT mapping (i.e., 16 entries) reduces the number of accessible colors but improves loading time. The data structure is loaded from a memory location defined by the address in the REG field.

48.4.3. GFX2D Visible Registers

48.4.3.1. Register Naming

A set of 15 registers is defined and accessible through the use of the load and store architecture.

Table 48.26. Visible Registers

Value	Name	Description
0	GFX2D_PA0	Surface 0 Physical Address Register
1	GFX2D_PITCH0	Surface 0 Pitch Register
2	GFX2D_CFG0	Surface 0 Configuration Register
3	GFX2D_PA1	Surface 1 Physical Address Register
4	GFX2D_PITCH1	Surface 1 Pitch Register
5	GFX2D_CFG1	Surface 1 Configuration Register
6	GFX2D_PA2	Surface 2 Physical Address Register
7	GFX2D_PITCH2	Surface 2 Pitch Register
8	GFX2D_CFG2	Surface 2 Configuration Register
9	GFX2D_PA3	Surface 3 Physical Address Register
10	GPREG0	General-Purpose Register 0
11	GPREG1	General-Purpose Register 1
12	GPREG2	General-Purpose Register 2
13	GPREG3	General-Purpose Register 3
14	GPREG4	General-Purpose Register 4
15	GPREG5	General-Purpose Register 5

General-purpose registers are generic registers. They can hold:

- an address,
- a constant color for a FILL or BLEND operation,
- a constant alpha value for a BLEND, or
- a user-defined 32-bit data for a STORE operation.

Table 48.27. General-Purpose Registers

Operation/ Instruction	General-Purpose Register
FILL	The register holds the 32-bit fill color pattern when the FILL arguments are less than 2. In that case, the color is defined by the REG field of the FILL instruction.
BLEND	The register holds the constant 32-bit color (A_c, R_c, G_c, B_c). It can be used for CONSTANT_ALPHA, CONSTANT_ALPHA parameters.

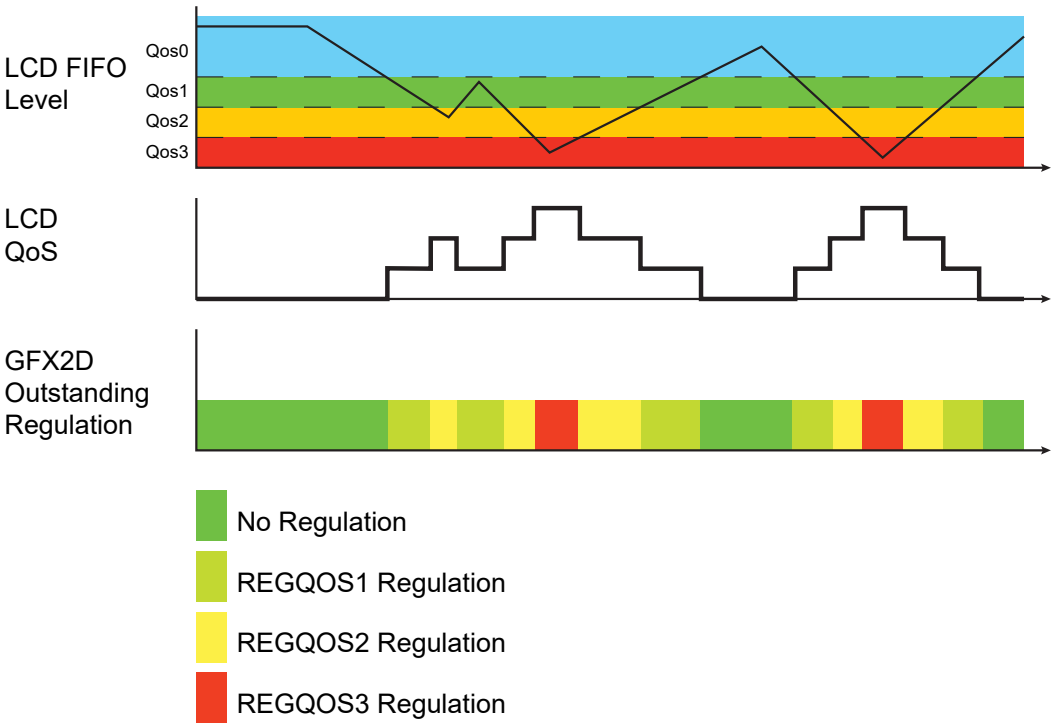
Table 48.27. General-Purpose Registers (continued)

Operation/ Instruction	General-Purpose Register
STR	The store operation requires a valid address defined by the REGAD field register index, and a data defined by the REG field register index. The general-purpose register can hold a 32-bit address or data.
LDR	The LDR instruction can load a general-purpose register.

48.4.3.2.Register Descriptions

Figure 48.3. Surface Registers

48.4.4. Traffic Balancing Using Outstanding Regulation



Global system performance is significantly impacted when the LCD controller is reading a frame buffer from memory to refresh the LCD screen. To ensure optimal performance, the LCD forwards its quality of service to other system bus hosts to limit their usage of the bus. The GFX2D frame rate is limited to allow latency-critical LCD operation.

Use the following procedure to activate traffic balancing:

1. Program the GFX2D_GC.REGQOS1, GFX2D_GC.REGQOS2 and GFX2D_GC.REGQOS3 registers and enable the outstanding issuance regulation by setting the GFX2D_GC.REGEN.
2. Configure the GFX2D_PCX register, and read the GFX2D_MCX register to adjust the regulation.

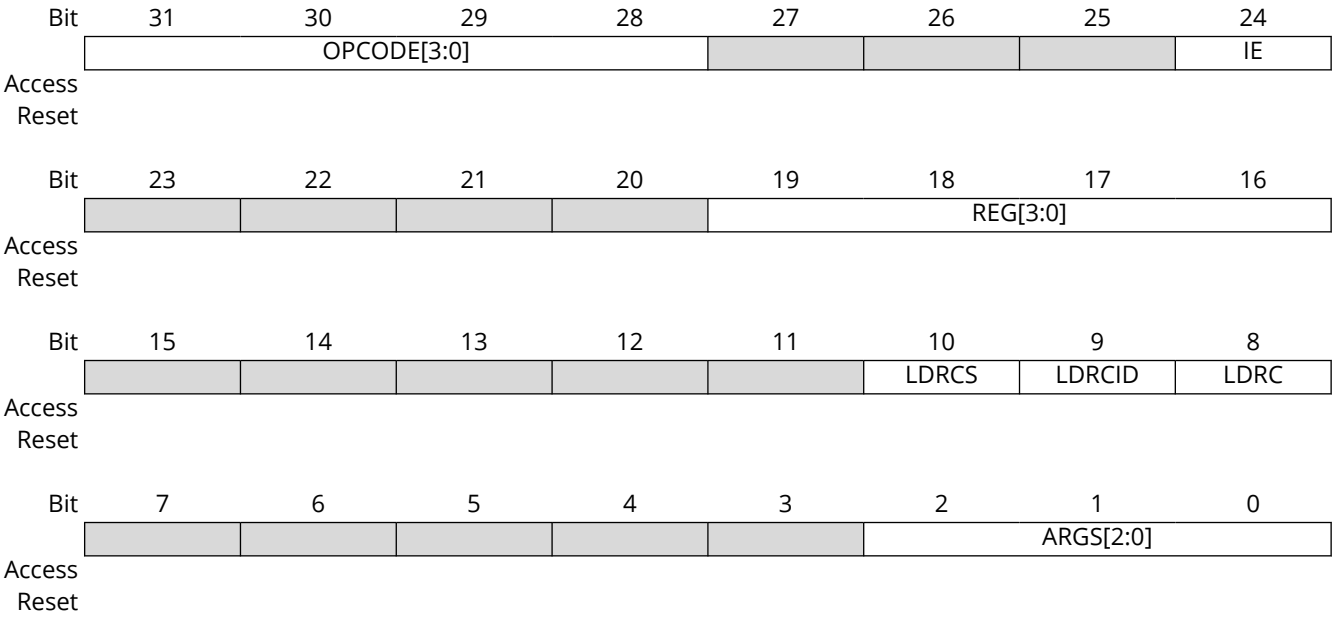
Figure 48.4. Traffic Balancing Using Outstanding Regulation

48.4.5. Data Flow Instructions

48.4.5.1. LDR Instruction



The LDR instruction length is variable and depends on the context.

- When the LDR instruction is used to load a register, the instruction length is 2 words.
- When the LDR instruction is used to load a CLUT, the instruction length is a single word.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.5.1.1.LDR_WD0

Name: LDR_WD0

Bits 31:28 – OPCODE[3:0] Instruction Code
This field must be set to '0x8'.

Bit 24 – IE Interrupt Enable

Value	Description
0	The End of Instruction interrupt is disabled.
1	The End of Instruction interrupt is enabled.

Bits 19:16 – REG[3:0] Register Identifier
This is the target register for a load operation. When the LDR instruction is used to load a Color Look-Up Table, the REG field points to the general-purpose register that holds the physical base address of the table.

Bit 10 – LDRCS Color Look-Up Table Size

Value	Description
0	256 entries.
1	16 entries.

Bit 9 – LDRCID Color Look-Up Table Selection

Value	Description
0	Table 0 is selected.
1	Table 1 is selected.

Bit 8 – LDRC Load Color Look-Up Table

Value	Description
0	Loads the register with the immediate value.
1	Loads the Color Look-Up Table with the content of the memory.

© 2026 Microchip Technology Inc. and its subsidiaries

Bits 2:0 – ARGS[2:0] Arguments Length
This field must be set to '0'.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.5.1.2.LDR_WD1

Name: LDR_WD1

Bit	31	30	29	28	27	26	25	24
	DATA[31:24]							
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

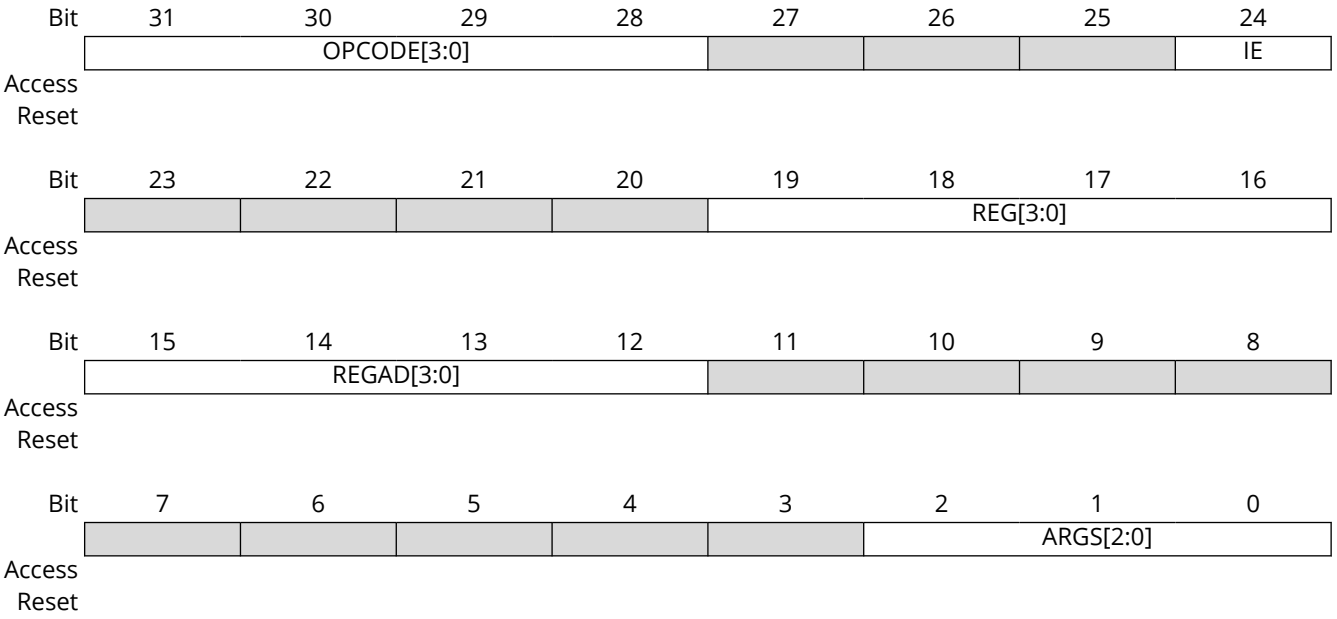
Bits 31:0 – DATA[31:0] 32-bit Data
The 32-bit data word loaded into the register.



48.4.5.2.STR Instruction

The instruction length is 1 word.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.5.2.1.STR_WD0

Name: STR_WD0

Bits 31:28 – OPCODE[3:0] Instruction Code
Must be set to '0x9'.

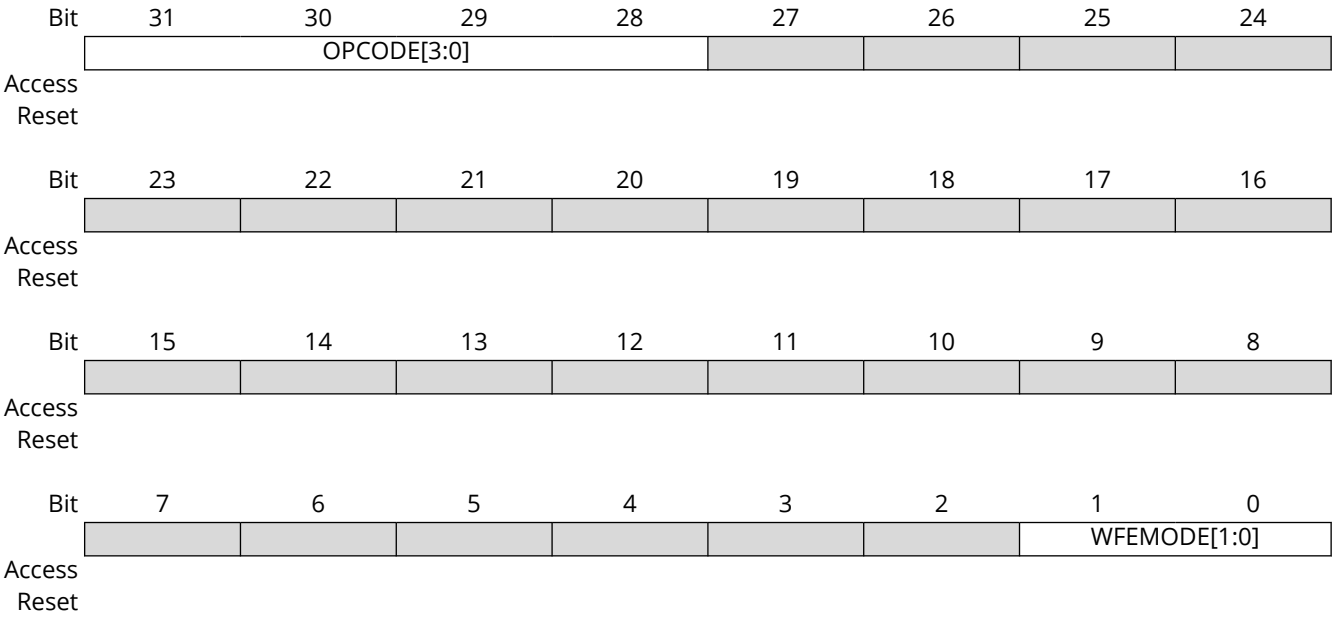
Bit 24 – IE Interrupt Enable

Value	Description
0	The End of Instruction interrupt is disabled.
1	The End of Instruction interrupt is enabled.

Bits 19:16 – REG[3:0] Register Identifier
Points to the general-purpose register that holds the data written to memory.

Bits 15:12 – REGAD[3:0] Register Identifier for Stored Address
Points to the general-purpose register that holds the address of the memory store operation.

Bits 2:0 – ARGS[2:0] Arguments Length
This field must be set to '0'.



48.4.5.3.WFE Instruction

The instruction length is 1 word.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.5.3.1.WFE_WD0

Name: WFE_WD0

Bits 31:28 – OPCODE[3:0] Instruction Code
This field must be set to '0xA'.

Bits 1:0 – WFEMODE[1:0] Wait For Event Mode

Value	Description
0	Resume from WFE state when detecting any edge on event signal
1	Resume from WFE state when detecting rising edge on event signal
2	Resume from WFE state when detecting falling edge on event signal

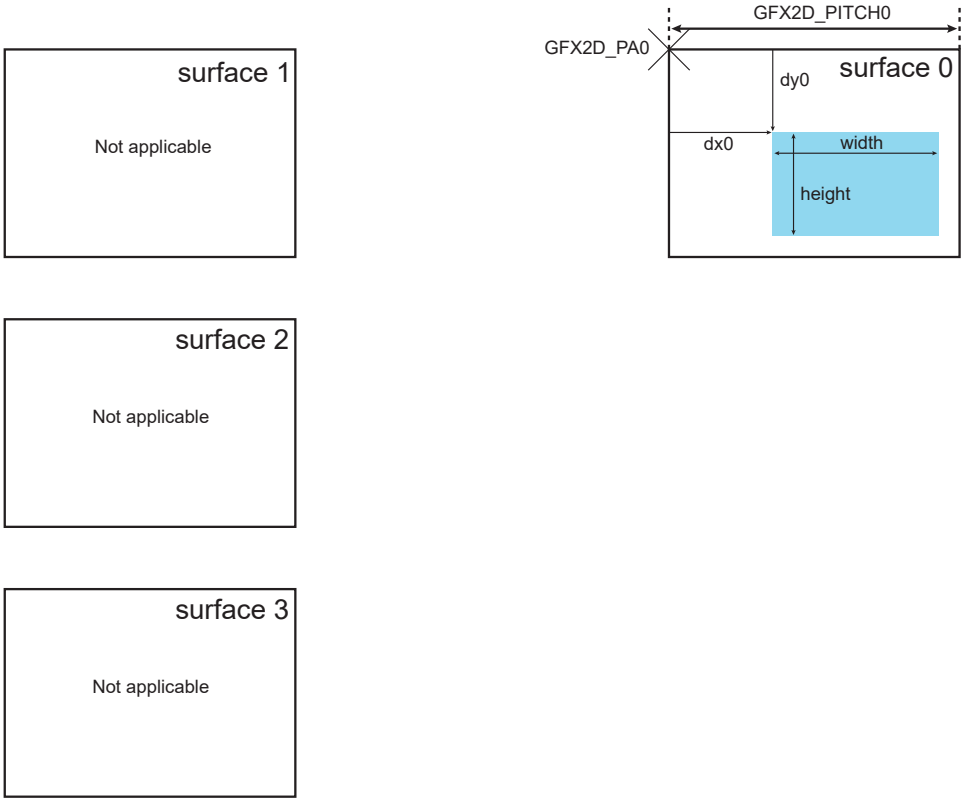
48.4.6. Graphics Instructions

48.4.6.1.FILL Instruction

The FILL instruction length is 4.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 48.5. Fill Operation



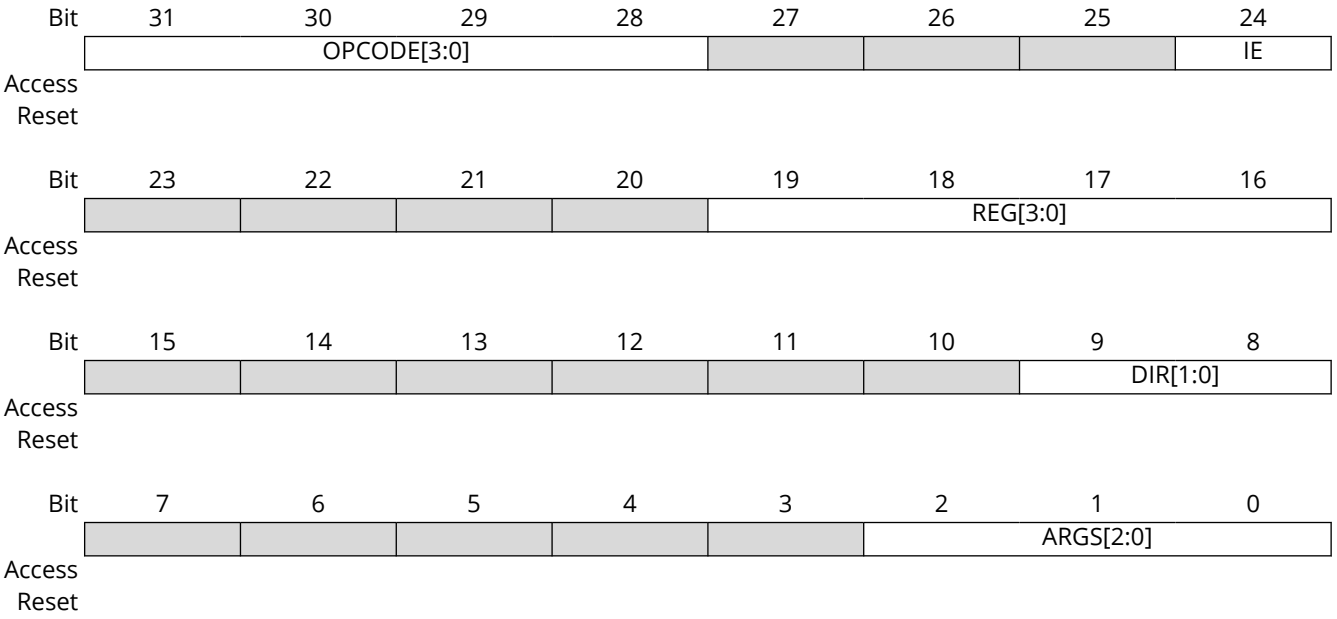


Table 48.28. FILL Instructions

Word Identifier	Description
FILL_WD0	The instruction header
FILL_WD1	The width and height of the destination-filled area
FILL_WD2	The x and y offsets of the filled area
FILL_WD3	The fill color: a 32-bit ARGB color resized to the area pixel format

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.6.1.1.FILL_WD0

Name: FILL_WD0

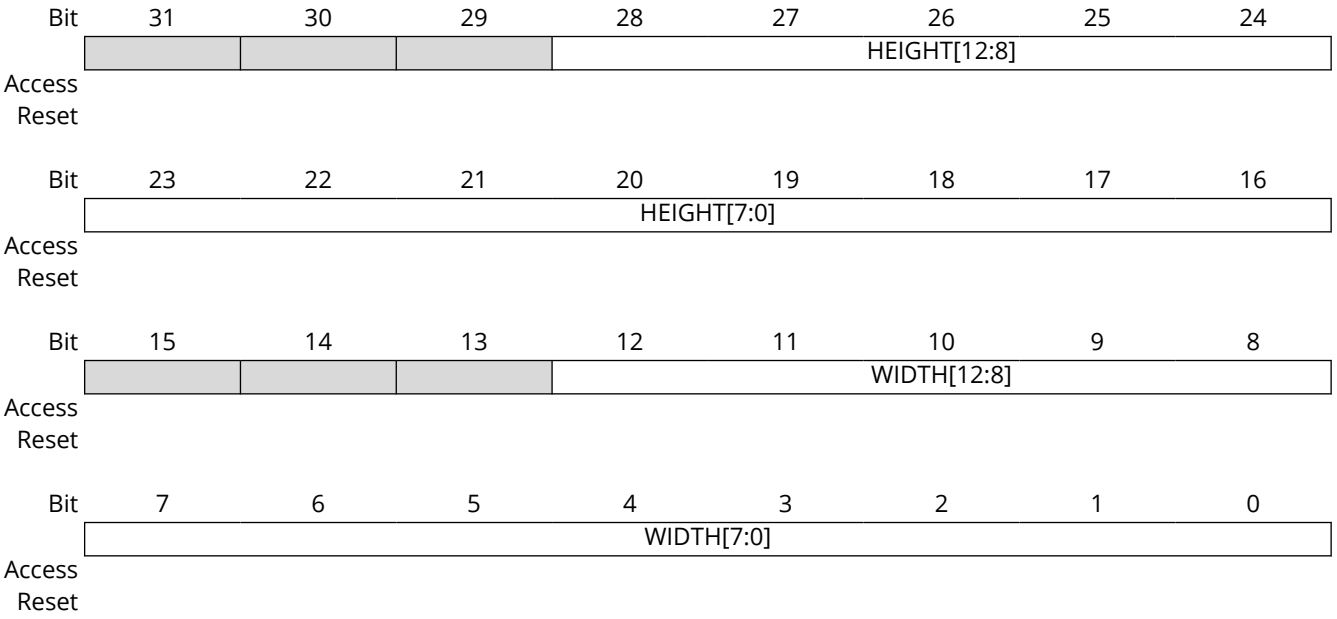
Bits 31:28 – OPCODE[3:0] Instruction Code
This field must be set to '0xB'.

Bit 24 – IE Interrupt Enable

Value	Description
0	The End of Instruction interrupt is disabled.
1	The End of Instruction interrupt is enabled.

Bits 19:16 – REG[3:0] Register Identifier
This field is relevant when ARGS is less than 2. In that case, the REG value points to a register with a valid 32-bit ARGB color.

Bits 9:8 – DIR[1:0] Transfer Direction



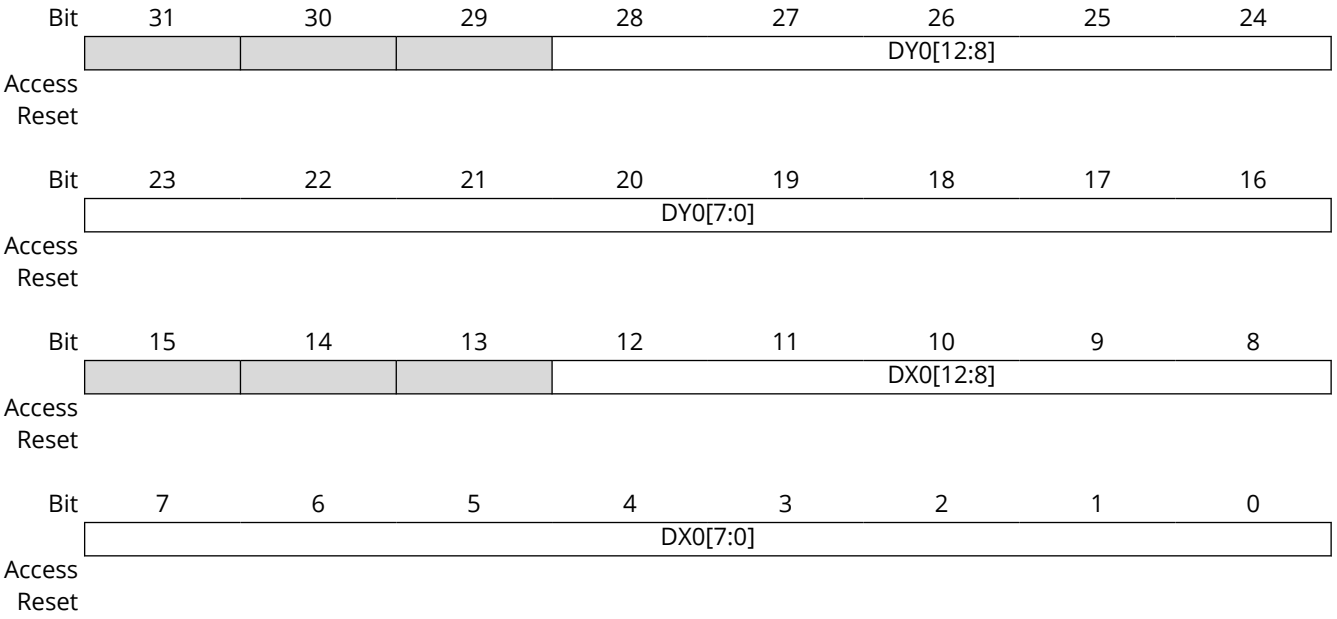
Value	Name	Description
0	XY00	Horizontal forward, vertical forward
1	XY01	Horizontal forward, vertical backward
2	XY10	Horizontal backward, vertical forward
3	XY11	Horizontal backward, vertical backward

Bits 2:0 – ARGS[2:0] Arguments Length
Must be less than or equal to 2.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.6.1.2.FILL_WD1

Name: FILL_WD1



Bits 28:16 – HEIGHT[12:0] Destination Surface Height
The surface height is set to (HEIGHT+1) pixels.

Bits 12:0 – WIDTH[12:0] Destination Surface Width
The surface width is set to (WIDTH+1) pixels.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.6.1.3.FILL_WD2

Name: FILL_WD2

Bits 28:16 – DY0[12:0] Destination Y Position
This field indicates the vertical position of the window.

Bits 12:0 – DX0[12:0] Destination X Position
This field indicates the horizontal position of the window.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.6.1.4.FILL_WD3

Name: FILL_WD3

Bit	31	30	29	28	27	26	25	24

Reset								

Bit	7	6	5	4	3	2	1	0
	B[7:0]							
Access								
Reset								

Bits 31:24 – A[7:0] Alpha Color Component Value
Program this field with the desired Alpha value.

Bits 23:16 – R[7:0] Red Color Component Value
Program this field with the desired Red value.

Bits 15:8 – G[7:0] Green Color Component Value
Program this field with the desired Green value.

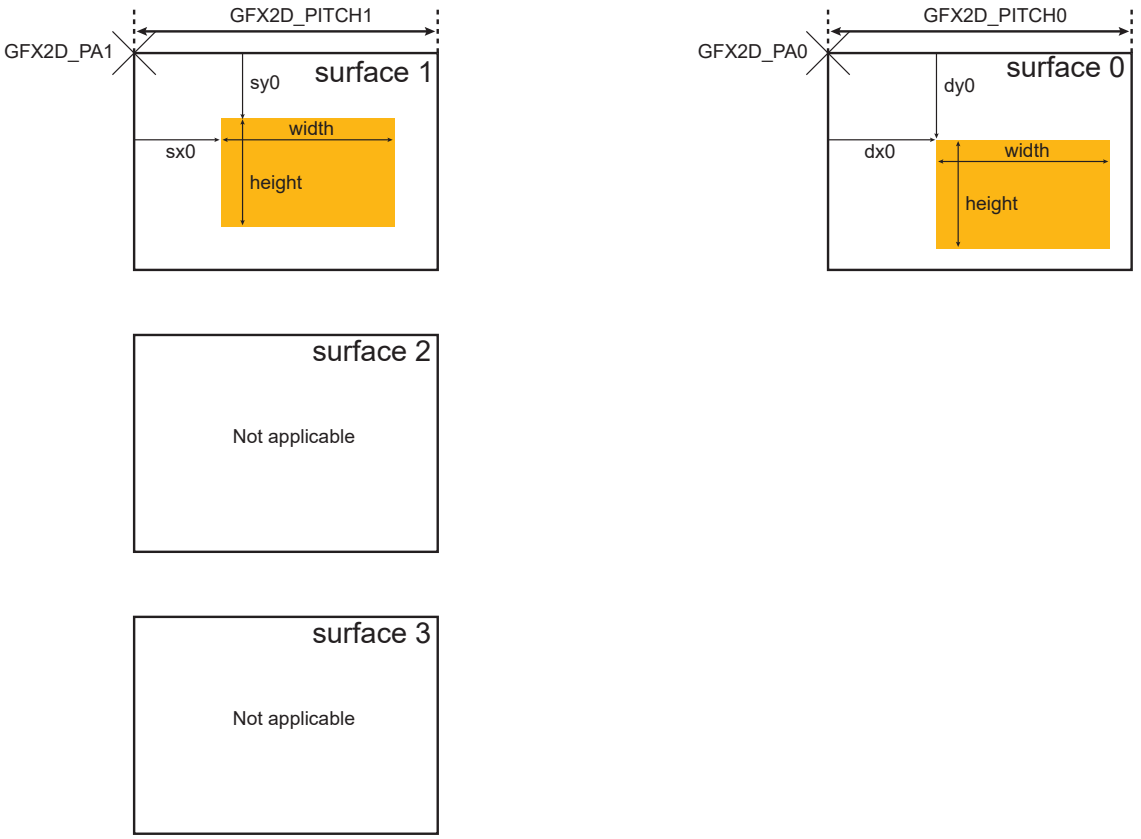
Bits 7:0 – B[7:0] Blue Color Component Value
Program this field with the desired Blue value.

48.4.6.2.COPY Instruction

The instruction length is 4 words.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 48.6. COPY Operation



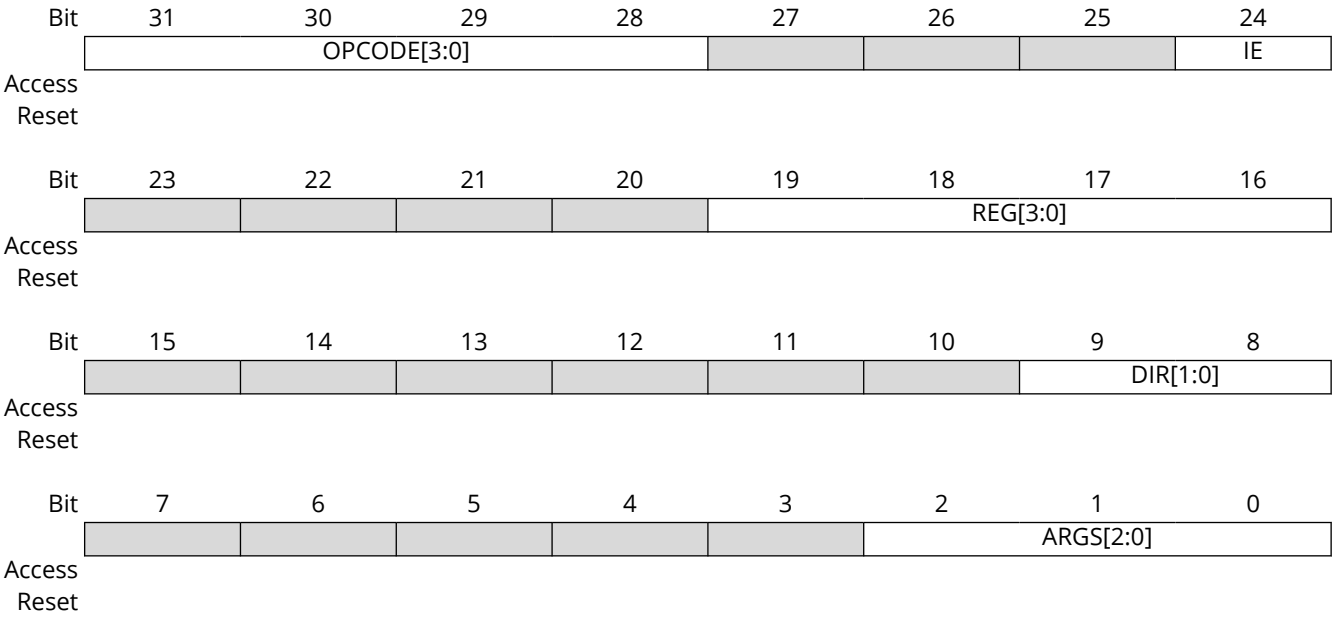


Table 48.29. COPY Instructions

Word Identifier	Description	Surface Register
COPY_WD0	The instruction header	Not applicable
COPY_WD1	The width and height of the destination area	Surface 0 register
COPY_WD2	The x and y offsets of the destination area	Surface 0 register
COPY_WD3	The x and y offsets of the source area	Surface 1 register

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.6.2.1.COPY_WD0

Name: COPY_WD0

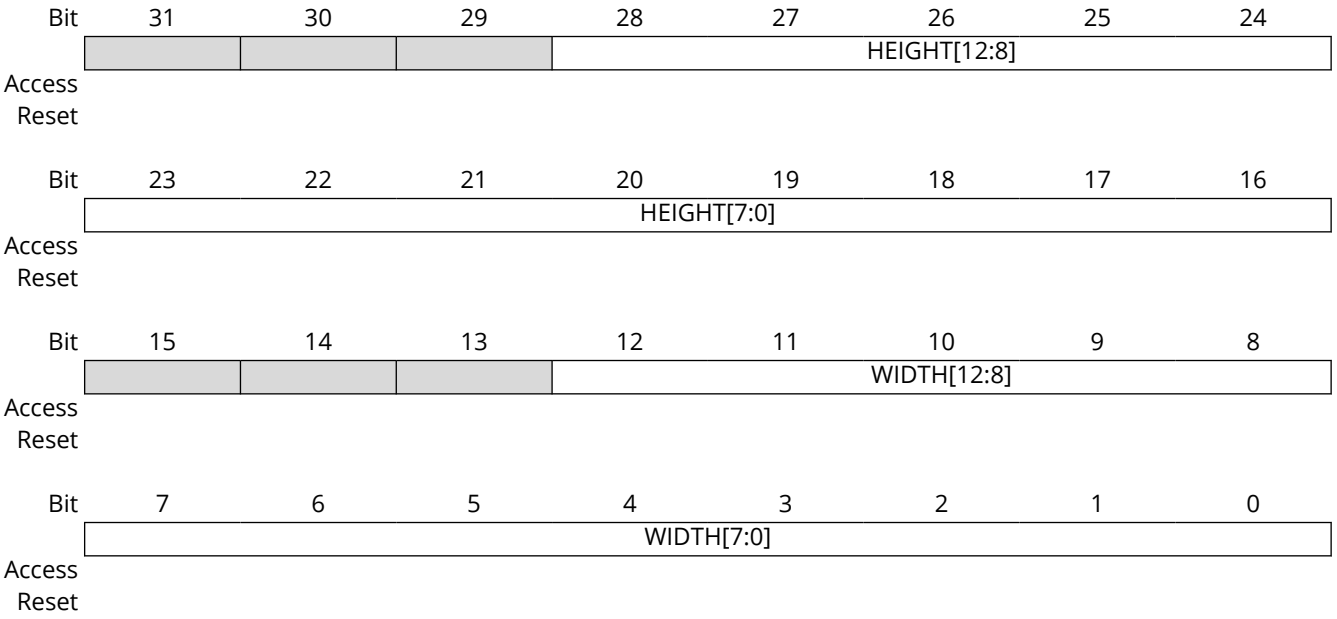
Bits 31:28 – OPCODE[3:0] Instruction Code
This field must be set to '0xC'.

Bit 24 – IE Interrupt Enable

Value	Description
0	The End of Instruction interrupt is disabled.
1	The End of Instruction interrupt is enabled.

Bits 19:16 – REG[3:0] Register Identifier
When a constant is used, the constant value is located in the register defined by the REG value.

Bits 9:8 – DIR[1:0] Transfer Direction



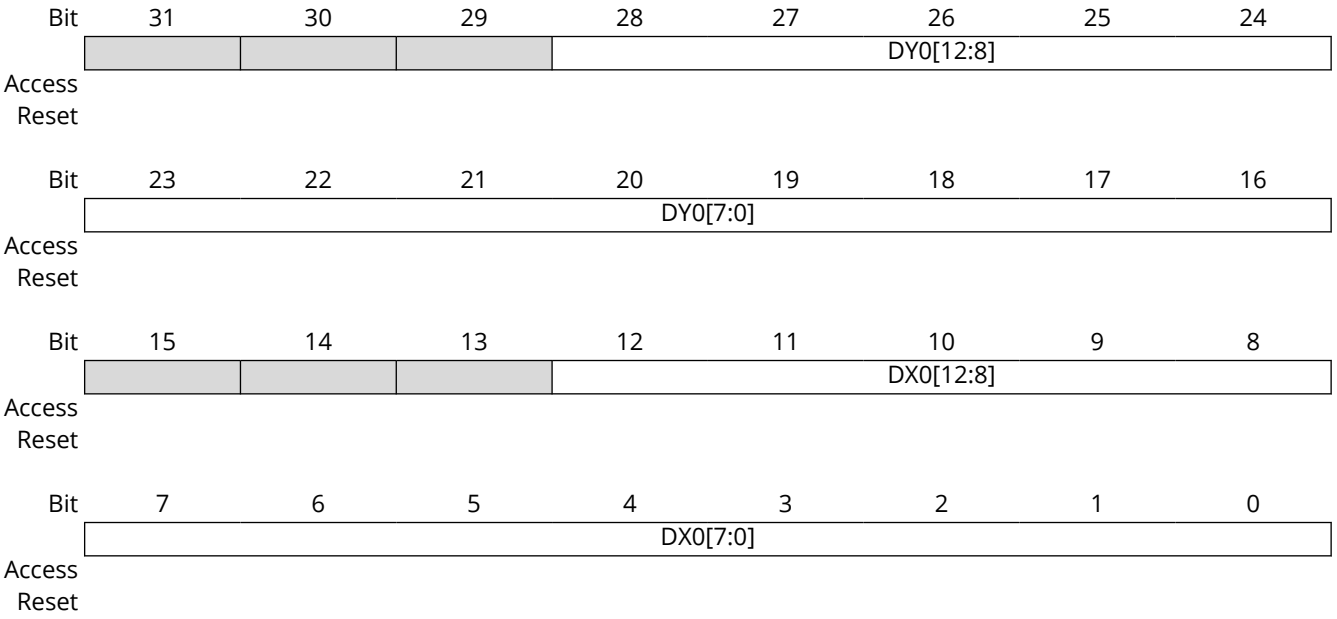
Value	Name	Description
0	XY00	Horizontal forward, vertical forward
1	XY01	Horizontal forward, vertical backward
2	XY10	Horizontal backward, vertical forward
3	XY11	Horizontal backward, vertical backward

Bits 2:0 – ARGS[2:0] Arguments Length
Must be set to '2'.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.6.2.2.COPY_WD1

Name: COPY_WD1



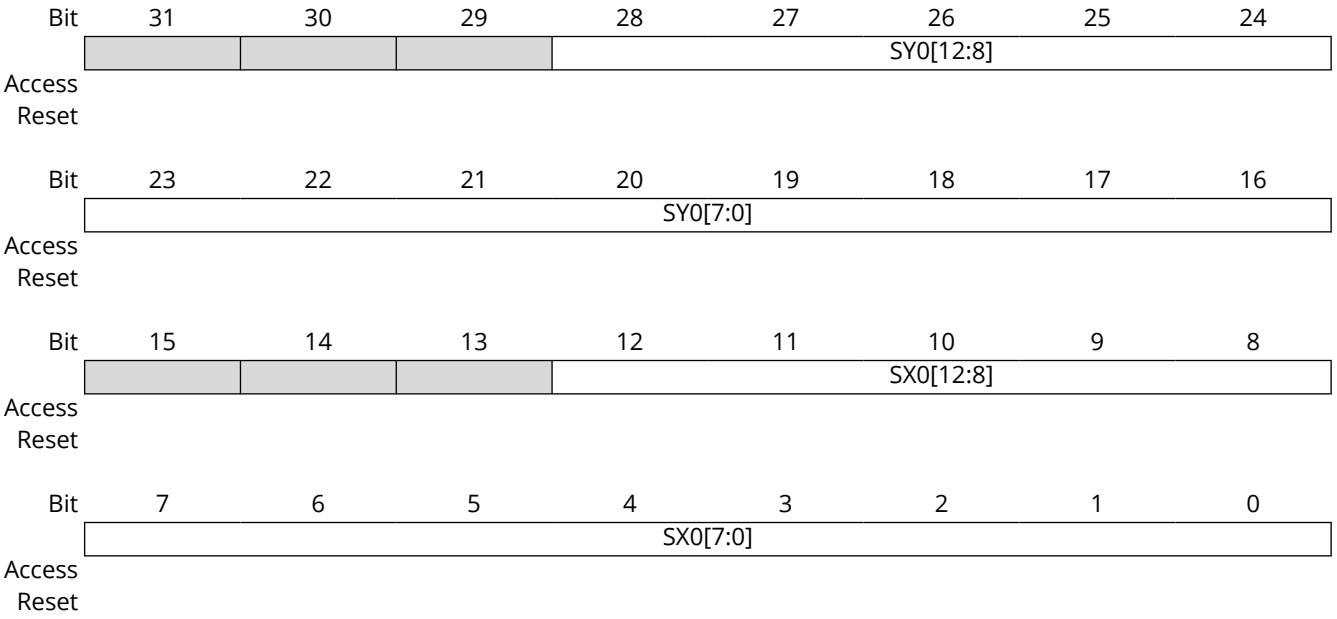
Bits 28:16 – HEIGHT[12:0] Destination Surface Height
The surface height is set to (HEIGHT+1) pixels.

Bits 12:0 – WIDTH[12:0] Destination Surface Width
The surface width is set to (WIDTH+1) pixels.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.6.2.3.COPY_WD2

Name: COPY_WD2



Bits 28:16 – DY0[12:0] Destination Y Position
This field indicates the vertical position of the window.

Bits 12:0 – DX0[12:0] Destination X Position
This field indicates the horizontal position of the window.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.6.2.4.COPY_WD3

Name: COPY_WD3

Bits 28:16 – SY0[12:0] Source Y Position
This field indicates the vertical position of the window.

Bits 12:0 – SX0[12:0] Source X Position
This field indicates the horizontal position of the window.

48.4.6.3.BLEND Instruction

The instruction length is 6 words.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 48.7. BLEND Operation

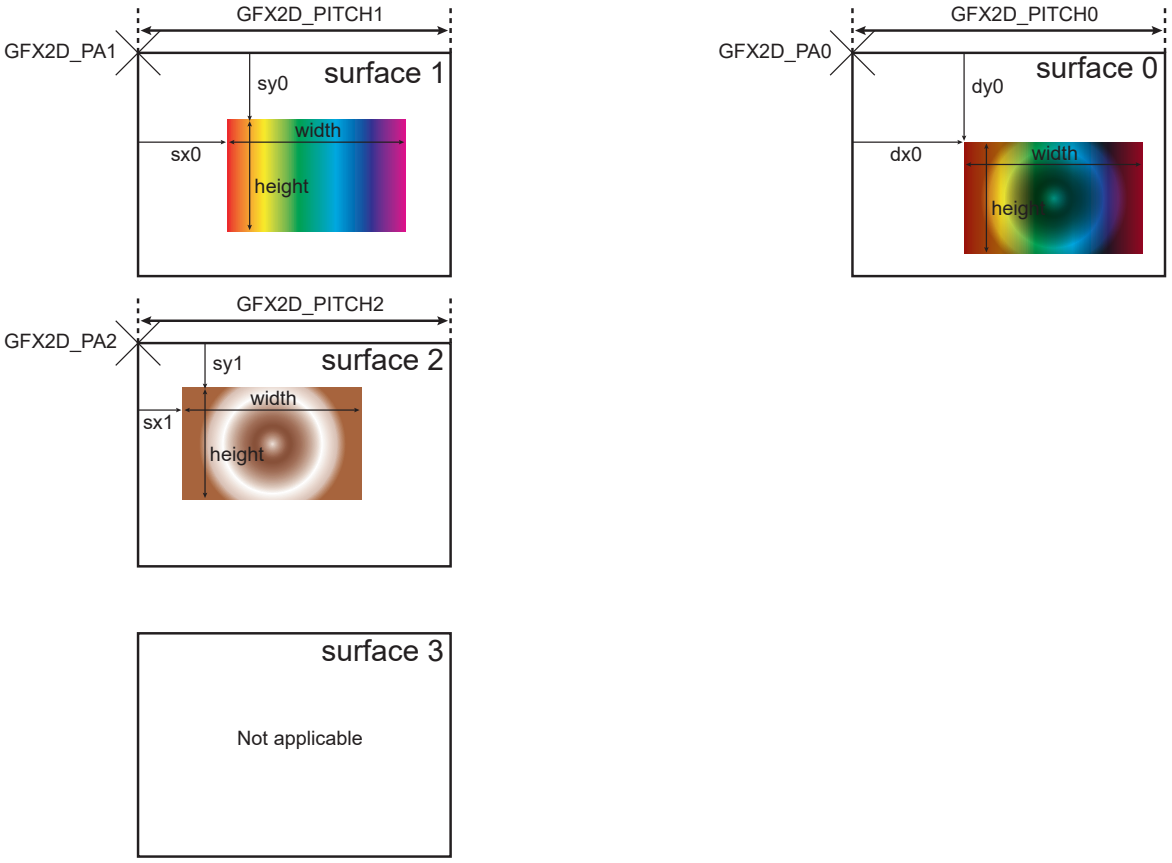


Table 48.30. BLEND Instructions

Word Identifier	Description	Surface Register
BLEND_WD0	The Instruction header	Not applicable
BLEND_WD1	The width and height of the destination area (C_f)	Surface 0 registers
BLEND_WD2	The x and y offsets of the destination area (C_f)	Surface 0 registers
BLEND_WD3	The x and y offsets of source 0 (C_d)	Surface 1 registers
BLEND_WD4	The x and y offsets of source 1 (C_s)	Surface 2 registers
BLEND_WD5	This register configures the blending functions and factors	Not applicable

Bit 23 – DPRE Destination Premult

Value	Description
0	Destination pre-multiplication is disabled.
1	Destination pre-multiplication is enabled. Pixel values from source or destination surfaces that are used to determine the value of the destination blending factors (D) are first multiplied by the constant (stored in the register pointed to by BLEND_WD0.DREG). Only the destination factor value is impacted. The pixel values used for the blending function input remain unchanged.

Bits 22:20 – DAFACT[2:0] Destination Alpha Factor

Value	Name	Description
0	ZERO	(0, 0, 0, 0)
1	ONE	(1, 1, 1, 1)
2	SRC_ALPHA	(A_s, A_s, A_s, A_s)
3	ONE_MINUS_SRC_ALPHA	(1, 1, 1, 1)-(A_s, A_s, A_s, A_s)
4	DST_ALPHA	(A_d, A_d, A_d, A_d)
5	ONE_MINUS_DST_ALPHA	(1, 1, 1, 1)-(A_d, A_d, A_d, A_d)
6	CONSTANT_ALPHA	(A_c, A_c, A_c, A_c)
7	ONE_MINUS_CONSTANT_ALPHA	(1, 1, 1, 1)-(A_c, A_c, A_c, A_c)

Bit 19 – SPRE Source Premult

Value	Description
0	Source pre-multiplication is disabled.
1	Source pre-multiplication is enabled. Pixel values from source or destination surfaces that are used to determine the value of the source blending factors (S) are first multiplied by the constant (stored in the register pointed to by BLEND_WD0.REG). Only the source factor value is impacted. The pixel values used for the blending function input remain unchanged.

Bits 18:16 – SAFACT[2:0] Source Alpha Factor

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
0	ZERO	(0, 0, 0, 0)
1	ONE	(1, 1, 1, 1)
2	SRC_ALPHA	(A_s, A_s, A_s, A_s)
3	ONE_MINUS_SRC_ALPHA	(1, 1, 1, 1)-(A_s, A_s, A_s, A_s)
4	DST_ALPHA	(A_d, A_d, A_d, A_d)
5	ONE_MINUS_DST_ALPHA	(1, 1, 1, 1)-(A_d, A_d, A_d, A_d)
6	CONSTANT_ALPHA	(A_c, A_c, A_c, A_c)
7	ONE_MINUS_CONSTANT_ALPHA	(1, 1, 1, 1)-(A_c, A_c, A_c, A_c)

Bits 15:12 – SPE[3:0] Special Blend

Value	Name	Description
0	LIGHTEN	Based on the color information in each channel, selects the base color or the blend color, whichever is lighter, as the resulting color.
1	DARKEN	Based on the color information in each channel, selects the base color or the blend color, whichever is darker, as the resulting color.
2	MULTIPLY	Based on the color information in each channel, multiplies the base color by the blend color. The result is always a darker color.
3	AVERAGE	Based on the color information in each channel, averages the base color and the blend color to generate the resulting color.
4	ADD	This blend mode adds pixel values.
5	SUBTRACT	Based on the color information in each channel, subtracts the blend color from the base color.
6	DIFFERENCE	Based on the color information in each channel, subtracts either the blend color from the base color or the base color from the blend color, depending on which has the greater brightness value.
7	NEGATION	This mode produces the opposite effect to difference.
8	SCREEN	Based on each channel's color information, multiplies the inverse of the blend and base colors. The resulting color is always a lighter color.
9	OVERLAY	Multiplies or screens the colors, depending on the base color.
10	DODGE	Based on the color information in each channel, brightens the base color to reflect the blend color by decreasing the contrast between the two.
11	BURN	Based on the color information in each channel, darkens the base color to reflect the blend color by increasing the contrast between the two.
12	REFLECT	This blend mode can be used to add shiny objects or area if light. Black pixels in the blend are ignored as if they were transparent.
13	GLOW	The reverse of the REFLECT mode. GLOW effectively brightens the composition by the amount of brightness in the blend layer. Black pixels in the blend layer are rendered as if they were transparent.

Bits 10:8 – FUNC[2:0] Blending Function

Value	Name	Description
0	ADD	C_f=S*C_s +D*C_d
1	SUBTRACT	C_f=S*C_s -D*C_d
2	REVERSE	C_f=D*C_d +S*C_s
3	MIN	C_f=Min(C_s, C_d)
4	MAX	C_f=Max(C_s, C_d)
5	SPE	Special blending functions

Bits 7:4 – DCFACT[3:0] Destination Color Factor

Value	Name	Description
0	ZERO	(0, 0, 0, 0)
1	ONE	(1, 1, 1, 1)
2	SRC_COLOR	(A_s, R_s, G_s, B_s)
3	ONE_MINUS_SRC_COLOR	(1, 1, 1, 1)-(A_s, R_s, G_s, B_s)
4	DST_COLOR	(A_d, R_d, G_d, B_d)

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
5	ONE_MINUS_DST_COLOR	(1, 1, 1, 1)-(A_d, R_d, G_d, B_d)
6	SRC_ALPHA	(A_s, A_s, A_s, A_s)
7	ONE_MINUS_SRC_ALPHA	(1, 1, 1, 1)-(A_s, A_s, A_s, A_s)
8	DST_ALPHA	(A_d, A_d, A_d, A_d)
9	ONE_MINUS_DST_ALPHA	(1, 1, 1, 1)-(A_d, A_d, A_d, A_d)
10	CONSTANT_COLOR	(A_c, R_c, G_c, B_c)
11	ONE_MINUS_CONSTANT_COLOR	(1, 1, 1, 1)-(A_c, R_c, G_c, B_c)
12	CONSTANT_ALPHA	(A_c, A_c, A_c, A_c)
13	ONE_MINUS_CONSTANT_ALPHA	(1, 1, 1, 1)-(A_c, A_c, A_c, A_c)
14	SRC_ALPHA_SATURATE	(1, i, i, i) where i is equal to the minimum between A_s and 1-A_d

Bits 3:0 – SCFACT[3:0] Source Color Factor

Value	Name	Description
0	ZERO	(0, 0, 0, 0)
1	ONE	(1, 1, 1, 1)
2	SRC_COLOR	(A_s, R_s, G_s, B_s)
3	ONE_MINUS_SRC_COLOR	(1, 1, 1, 1)-(A_s, R_s, G_s, B_s)
4	DST_COLOR	(A_d, R_d, G_d, B_d)
5	ONE_MINUS_DST_COLOR	(1, 1, 1, 1)-(A_d, R_d, G_d, B_d)
6	SRC_ALPHA	(A_s, A_s, A_s, A_s)
7	ONE_MINUS_SRC_ALPHA	(1, 1, 1, 1)-(A_s, A_s, A_s, A_s)
8	DST_ALPHA	(A_d, A_d, A_d, A_d)
9	ONE_MINUS_DST_ALPHA	(1, 1, 1, 1)-(A_d, A_d, A_d, A_d)
10	CONSTANT_COLOR	(A_c, R_c, G_c, B_c)
11	ONE_MINUS_CONSTANT_COLOR	(1, 1, 1, 1)-(A_c, R_c, G_c, B_c)
12	CONSTANT_ALPHA	(A_c, A_c, A_c, A_c)
13	ONE_MINUS_CONSTANT_ALPHA	(1, 1, 1, 1)-(A_c, A_c, A_c, A_c)
14	SRC_ALPHA_SATURATE	(1, i, i, i) where i is equal to the minimum between A_s and 1-A_d

Bit 24 – IE Interrupt Enable

Value	Description
0	The End of Instruction interrupt is disabled.
1	The End of Instruction interrupt is enabled.

Bits 19:16 – REG[3:0] Register Identifier
When a constant is used, the constant value is located in the register defined by the REG value.

Bits 2:0 – ARGS[2:0] Arguments Length
Must be set to '5'.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.6.4.2.ROP_WD1

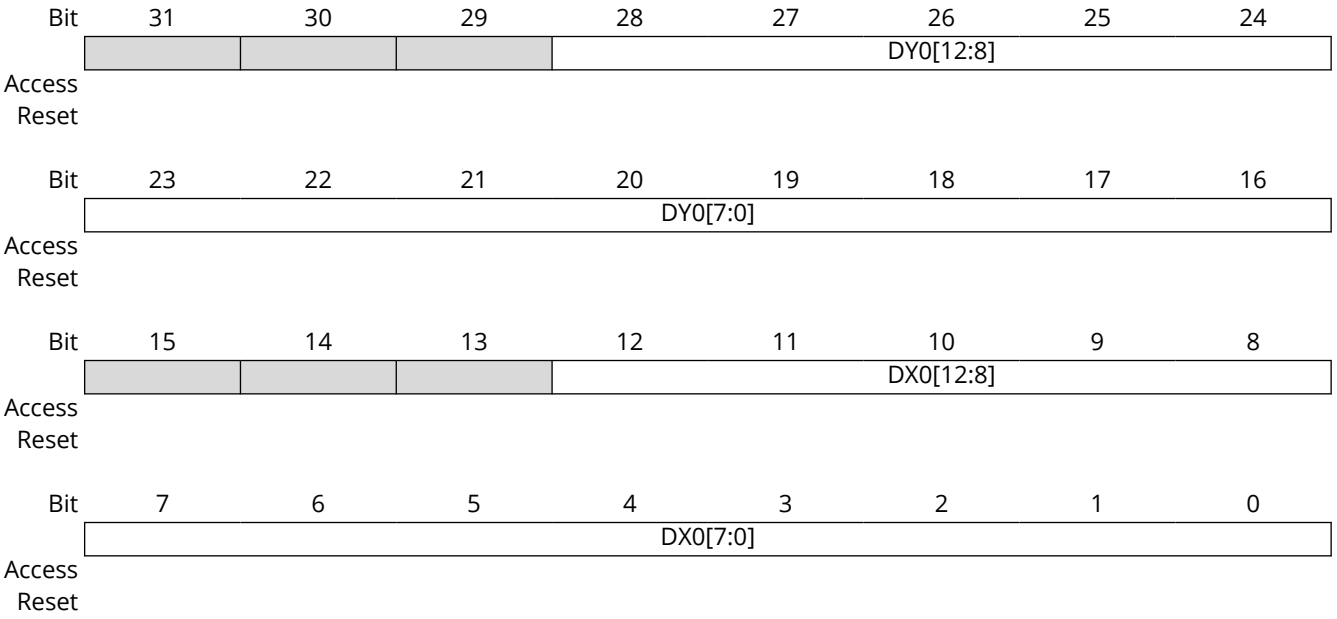
Name: ROP_WD1

Bit	31	30	29	28	27	26	25	24
				HEIGHT[12:8]				
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
	HEIGHT[7:0]							
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
				WIDTH[12:8]				
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	WIDTH[7:0]							
Access								
Reset								



Bits 28:16 – HEIGHT[12:0] Destination Surface Height
The surface height is set to (HEIGHT+1) pixels.

Bits 12:0 – WIDTH[12:0] Destination Surface Width
The surface width is set to (WIDTH+1) pixels.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.6.4.3.ROP_WD2

Name: ROP_WD2

Bits 28:16 – DY0[12:0] Destination Y Position
This field indicates the vertical position of the window.

Bits 12:0 – DX0[12:0] Destination X Position
This field indicates the horizontal position of the window.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.6.4.4.ROP_WD3

Name: ROP_WD3

Bit	31	30	29	28	27	26	25	24
				SY0[12:8]				
Access

Access								
Reset								

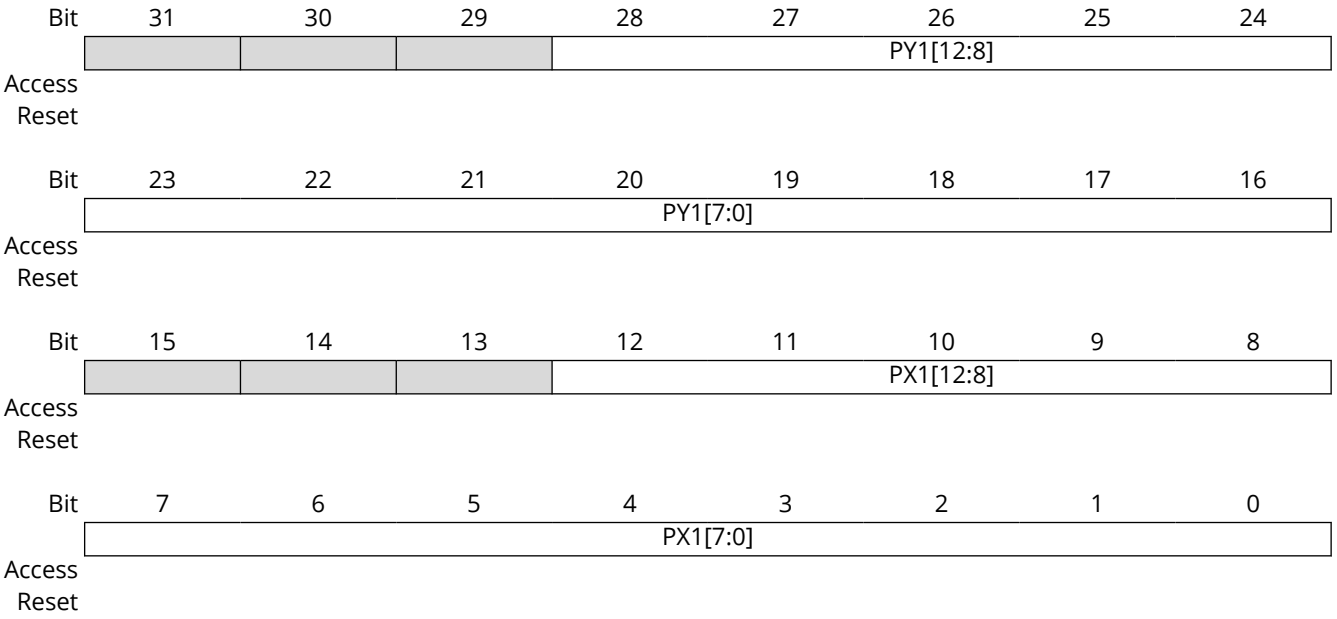
Bit	7	6	5	4	3	2	1	0
	SX0[7:0]							
Access								
Reset								



Bits 28:16 – SY0[12:0] Source Y Position
This field indicates the vertical position of the window.

Bits 12:0 – SX0[12:0] Source X Position
This field indicates the horizontal position of the window.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.6.4.5.ROP_WD4

Name: ROP_WD4

Bits 28:16 – PY1[12:0] Pattern Y Position
This field indicates the pattern Y position of the window.

Bits 12:0 – PX1[12:0] Pattern X Position
This field indicates the pattern X position of the window.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.6.4.6.ROP_WD5

Name: ROP_WD5

Bit	31	30	29	28	27	26	25	24
	PMASK[31:24]							
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Bit	7	6	5	4	3	2	1	0
	PMASK[7:0]							
Access								
Reset								

Bits 31:0 – PMASK[31:0] Mask Pointer
This field must be set to the 32-bit address of the mask memory location.

© 2026 Microchip Technology Inc. and its subsidiaries

48.4.6.4.7.ROP_WD6

Name: ROP_WD6

Bits 17:16 – ROPM[1:0] Raster Operation Mode

Value	Name	Description
0	ROP2	Binary raster operation (D, S) Two surfaces are used (required), 16 operations are defined, D and S required. Mask set to 0 internally Pattern set to 0 internally Source read from memory ROPL field value is used to generate the logical expression. ROPL can be any value between 0 and 15 (0x00 to 0x0F). ROPH field is ignored. ROP2_BLACK D = 0 (always 0, black in RGB mode) ROP2_NOTMERGESOURCE D = ~(D|S) Inverse of R2_MERGESOURCE ROP2_MASKNOTSOURCE D = D &~S Conjunction of destination and inverse of source ROP2_NOTCOPYSOURCE D = ~S Inverse of source color ROP2_MASKSOURCENOT D = S & ~D Conjunction of source and inverse of destination ROP2_NOT D = ~D Inverse of destination ROP2_XORSOURCE D = D ^ S Exclusive OR of destination and source ROP2_NOTMASKSOURCE D = ~(D&S) Inverse of ROP2_MASKSOURCE ROP2_MASKSOURCE D = D & P Conjunction of destination and source ROP2_NOTXORSOURCE D = ~(D ^ S) Inverse of ROP2_XORSOURCE ROP2_NOP D = D No change (copy) ROP2_MERGENOTSOURCE D = D | ~S Disjunction of destination and inverse of source ROP2_COPYSOURCE D = S ROP2_MERGESOURCENOT D = S | ~D Disjunction of source and inverse of destination ROP2_MERGESOURCE D = S | D Conjunction of source and destination

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
		ROP2_WHITE D = 1
1	ROP3	Ternary raster operation (D, P, S) Three surfaces used, 256 operations Mask value set to 0 Source read from memory Pattern read from memory ROPL used to generate the logical expression 256 raster operations from 0x00 to 0xFF
2	ROP4	4-operand raster operation (D, P, S, M) Four surfaces used, 256 operations Mask value is read from memory (pointed by PMASK), mask is bit level. Source read from memory Pattern read from memory ROPL used to generate the logical expression when mask bit is cleared ROPH used to generate the logical expression when mask bit is set

Bits 15:8 – ROPH[7:0] 8-bit Raster Operation High

Bits 7:0 – ROPHL[7:0] 8-bit Raster Operation Low

		MTY		REGEN				
Access		R/W		R/W				
Reset		0		0				

Bits 19:16 – REGQOS3[3:0] Regulation for QoS Level 3
This register indicates the number of clock cycles inserted between outstanding transactions. The number of clock cycles added is calculated as follows.

$$\text{Latency} = 2^{\text{REGQOS3}} - 1$$

The maximum number of clock cycles is 1023.

Bits 15:12 – REGQOS2[3:0] Regulation for QoS Level 2
This register indicates the number of clock cycles inserted between outstanding transactions. The number of clock cycles added is calculated as follows.

$$\text{Latency} = 2^{\text{REGQOS2}} - 1$$

The maximum number of clock cycles is 1023.

Bits 11:8 – REGQOS1[3:0] Regulation for QoS Level 1
This register indicates the number of clock cycles inserted between outstanding transactions. The number of clock cycles added is calculated as follows.

$$\text{Latency} = 2^{\text{REGQOS1}} - 1$$

The maximum number of clock cycles is 1023.

Bit 6 – MTY Memory Tile Access

Value	Description
0	GFX2D uses tile accesses.
1	GFX2D uses linear accesses.

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 4 – REGEN Outstanding Regulation Enable

Value	Description
0	Outstanding Regulation is disabled.
1	Outstanding Regulation is enabled.

© 2026 Microchip Technology Inc. and its subsidiaries

48.5.2. GFX2D Global Enable Register

Name: GFX2D_GE
Offset: 0x04
Reset: 0x00000000
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
								WFERES
Access								W
Reset								0

Bit	7	6	5	4	3	2	1	0
								DISABLE
Access								W
Reset								0

Bit 8 – WFERES WFE Software Resume bit

Value	Description
0	No effect.
1	Exits the WFE state in software.

Bit 0 – DISABLE GFX2D Disable Bit

Value	Description
0	No effect.
1	Disables the graphics engine.

© 2026 Microchip Technology Inc. and its subsidiaries

48.5.4. GFX2D Global Status Register

Name: GFX2D_GS
Offset: 0x0C
Reset: 0x00000000
Property: Read-only

Bit	7	6	5	4	3	2	1	0
				BUSY				STATUS
Access				R				R
Reset				0				0

Bit 8 – WFEIP Wait For Event Status bit

Value	Description
0	The graphics core is running.
1	The graphics core is waiting for an event.

Bit 4 – BUSY GFX2D Busy Bit

Value	Description
0	The graphics core is in idle state.
1	The graphics core is busy.

Bit 0 – STATUS GFX2D Status Bit

Value	Description
0	The graphics engine is disabled.
1	The graphics engine is enabled.

Bit	7	6	5	4	3	2	1	0
				IERR	BERR	RERR	EXEND	RBEMPTY
Access				R	R	R	R	R
Reset				0	0	0	0	0

Bit 4 – IERR Illegal Instruction Interrupt Status Bit

Value	Description
0	The interrupt source is masked or no Illegal Instruction interrupt is pending.
1	An Illegal Instruction interrupt is pending.

Bit 3 – BERR Write Error Interrupt Status Bit

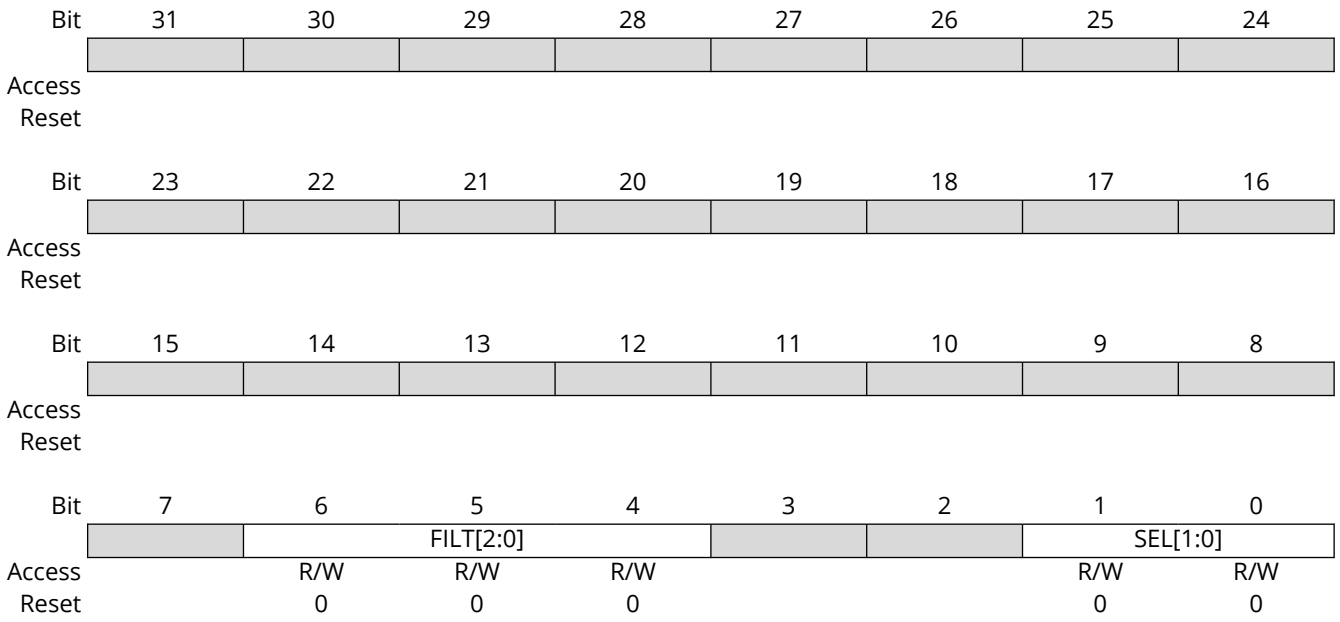
Value	Description
0	Either the interrupt source is masked or no Write Error interrupt is pending.
1	A Write Error interrupt is pending.

Bit 2 – RERR Read Error Interrupt Status Bit

Value	Description
0	Either the interrupt source is masked or no read error interrupt is pending.
1	An interrupt is pending.

Bit 1 – EXEND End of Execution Status Bit

Value	Description
0	Either the interrupt source is masked or no End of Execution interrupt is pending.
1	An End of Execution interrupt is pending (i.e. EXEND is '1' when GFX2D_GS.BUSY is set to '0').



Bit 0 – RBEMPTY Ring Buffer Empty Interrupt Status Bit

Value	Description
0	The Ring Buffer Empty interrupt has not occurred.
1	The Ring Buffer Empty interrupt has occurred since the last read of the status register.

© 2026 Microchip Technology Inc. and its subsidiaries

48.5.9. GFX2D Performance Configuration 0 Register

Name: GFX2D_PC0
Offset: 0x20
Reset: 0x00000000
Property: Read/Write

Bits 6:4 – FILT[2:0] Filter Configuration

Value	Name	Description
0	DISABLED	The filter is disabled.
1	QOS0	Events are valid when input QoS is equal to 0.
2	QOS1	Events are valid when input QoS is equal to 1.
3	QOS2	Events are valid when input QoS is equal to 2.
4	QOS3	Events are valid when input QoS is equal to 3.

Bits 1:0 – SEL[1:0] Performance Metrics Selection

Value	Name	Description
0	DISABLED	The performance counter is disabled and reset.
1	READ	The performance counter is incremented when a Read access is performed.
2	WRITE	The performance counter is incremented when a Write access is performed
3	CYCLE	Number of clock cycles

© 2026 Microchip Technology Inc. and its subsidiaries

48.5.10. GFX2D Metrics Counter 0 Register

Name: GFX2D_MC0

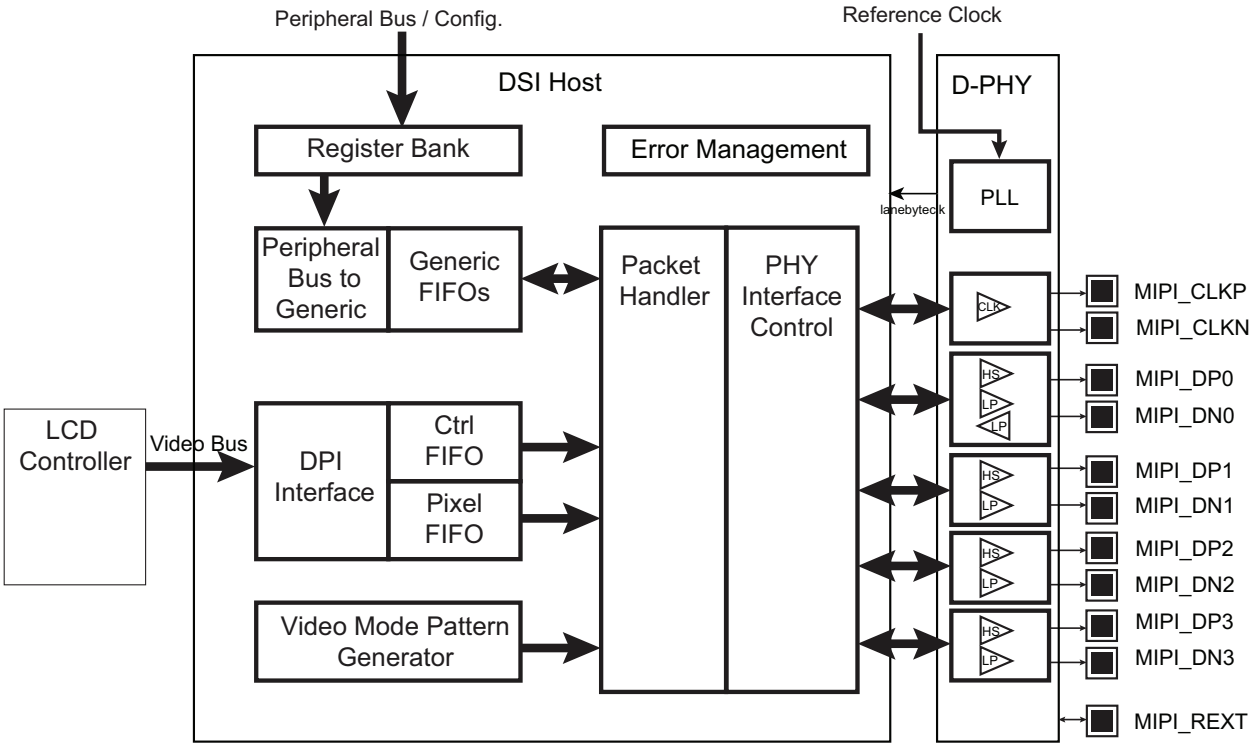
49. Display Serial Interface (DSI)

49.1. Description

The MIPI Display Serial Interface (DSI) Host Controller is a digital core that implements all protocol functions defined in the MIPI DSI Specification. The DSI host provides an interface between the LCD Controller (LCDC) and the MIPI D-PHY, allowing communication with a DSI-compliant display.



49.2. Embedded Characteristics

- Supports All Commands Defined in the MIPI Alliance Specification for Display Command Set (DCS)
  - Transmission of all Command mode packets through the APB interface
  - Transmission of commands in Low-Power mode and High-Speed mode during Video mode
- Supports Up to 1 Gbps per Lane
- Supports Up to 4 Data Lanes
- Bidirectional Communication and Escape Mode Support Through Data Lane 0
- Supports Continuous and Non-continuous Clock in D-PHY Clock Lane for Additional Power Saving
- Supports Ultra-Low-Power Mode with PLL Disabled
- ECC and Checksum Capabilities
- Fault Recovery Schemes
- 3D Transmission Support
- Color Coding Mappings:
  - DPI-2 16-bit RGB, configurations 1, 2, and 3
  - DPI-2 18-bit RGB, configurations 1 and 2
  - DPI-2 24-bit RGB
- Video Pattern Generator
- Auto Ultra-Low-Power Mode Control Scheme

MIPI_DP3	MIPI D-PHY differential output data lane 3	Input/Output
MIPI_DN3		
MIPI_REXT	Calibration reference resistor	Input/Output

49.5. Product Dependencies

49.5.1. I/O Lines

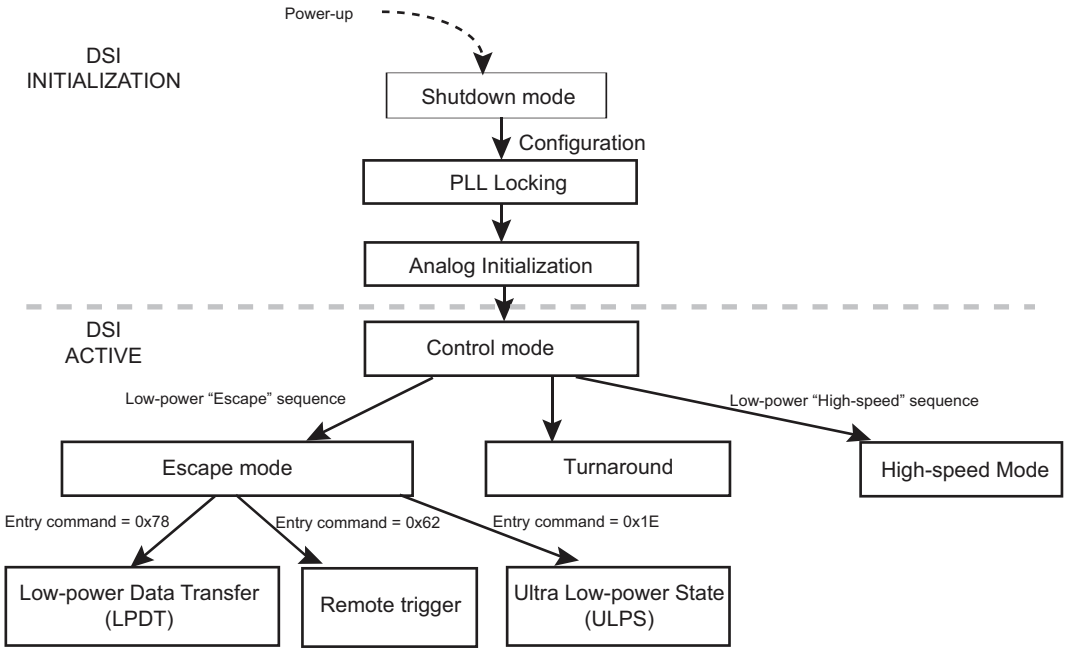
The D-PHY can be used either by DSI or CSI hosts. The programmer must first configure a dedicated a Special Function register to connect D-PHY to the DSI (refer to the section “Special Function Register (SFR)”).

© 2026 Microchip Technology Inc. and its subsidiaries

49.5.2. Power Management

The DSI is not continuously clocked. Before using it, the programmer must first enable the DSI and MIPI D-PHY peripheral clocks in the Power Management Controller (PMC).

49.5.3. Interrupt Sources



The DSI interrupt line is connected to one of the internal sources of the interrupt controller. Using the DSI interrupt requires prior programming of the interrupt controller.

49.6. Functional Description

49.6.1. D-PHY Operating Modes

The following figure illustrates the D-PHY initialization from Shutdown to Active modes.

Figure 49.2. D-PHY Initialization from Shutdown to Control Modes

49.6.1.1.Initialization

49.6.1.1.1.Shutdown Mode

Shutdown mode is the mode with the lowest power consumption, where all analog blocks are disabled, and digital logic is reset.

To enter this mode, set bits DPHY_RSTZ and SHUTDOWNZ in the Reset and PLL Control register (DSI_DPHY_RSTZ) to '0'.

In Shutdown mode, the differential lines of MIPI_DNx/Px and MIPI_CLKN/P are high impedance (Hi-Z).

By default, the D-PHY is configured to work only on the lower operation range of 80-110 Mbps. If higher bit rate operation is required, the D-PHY hsfreqrange must be programmed as defined in Frequency Ranges. If the D-PHY is always expected to function at the same bit rate, this additional step can be performed while in Shutdown mode. For more information on these options, refer to Active Modes.

When DSI_DPHY_RSTZ.DPHY_RSTZ and DSI_DPHY_RSTZ.SHUTDOWNZ are set to '1', the D-PHY exits Shutdown mode and starts an initialization procedure.

© 2026 Microchip Technology Inc. and its subsidiaries

49.6.1.1.2.PLL Locking Mode and Analog Initialization

The PLL is fed by the main crystal oscillator.

The D-PHY consists of 4 data lanes, but applications can use 4 or fewer data lanes. The number of lanes is configured in the field N_LANES in the D-PHY Interface Configuration register (DSI_DPHY_IF_CFG). Configuration of this field must be done prior to exiting Shutdown mode.

Prior to starting normal operation, the following D-PHY parameters must be configured:

- frequency range (refer to High-Speed Frequency Range Control Operation)
- PLL parameters (refer to D-PHY PLL Control Operation).

The initialization period is a protocol-dependent parameter with a minimum of 100 µs defined by the specification.

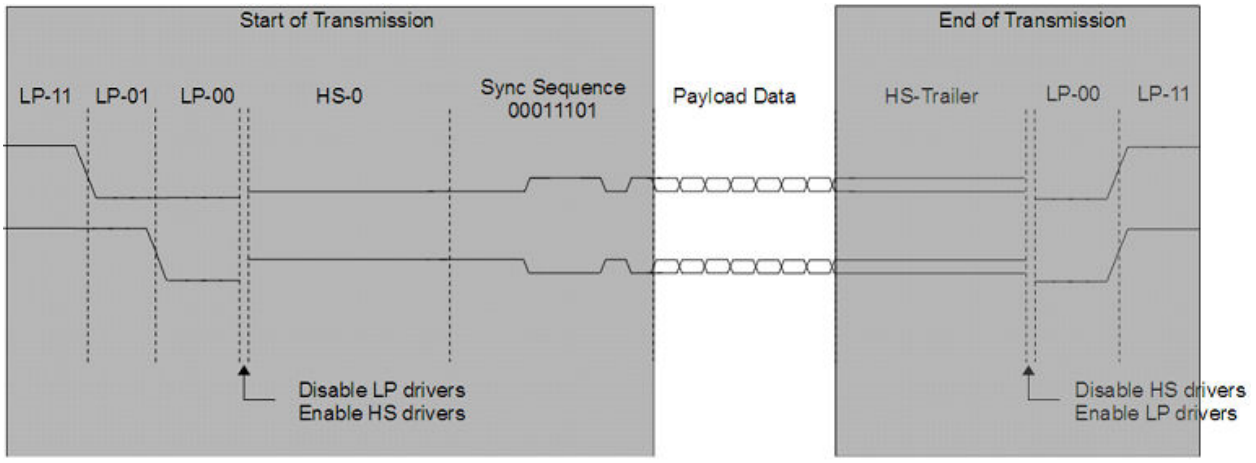
The D-PHY starts decoding the low-power commands after the analog initialization.

49.6.1.2.Active Modes

49.6.1.2.1.Control Mode

Control mode is the default operating mode. After the initialization is completed (analog calibrations and PLL locking), the D-PHY remains in this default mode until a request is placed. The request is placed either by the protocol layer for transmission, or directly through the sequence of low-power signals in the lanes in case of reception. While in Control mode, the transmitter side sets the LP-11 state in the lines - this is called the Stop state. The receiver side remains in Control mode while receiving LP-11 in the lines. Any request must start from and end in Stop state.

Following a request, a lane can leave Control mode for either High-Speed Data Transfer mode, Escape mode, Ultra-Low-Power state, or turnaround operation.



49.6.1.2.2.High-Speed Data Transfer Mode

High-speed data transfer occurs in bursts. The lane is in High-Speed mode only during these bursts. A high-speed burst must start from and return to a Stop state (Control mode).

High-speed data bursts are independent for each lane, which means that each data lane can start and end a high-speed transmission independently of the state of the remaining data lanes.

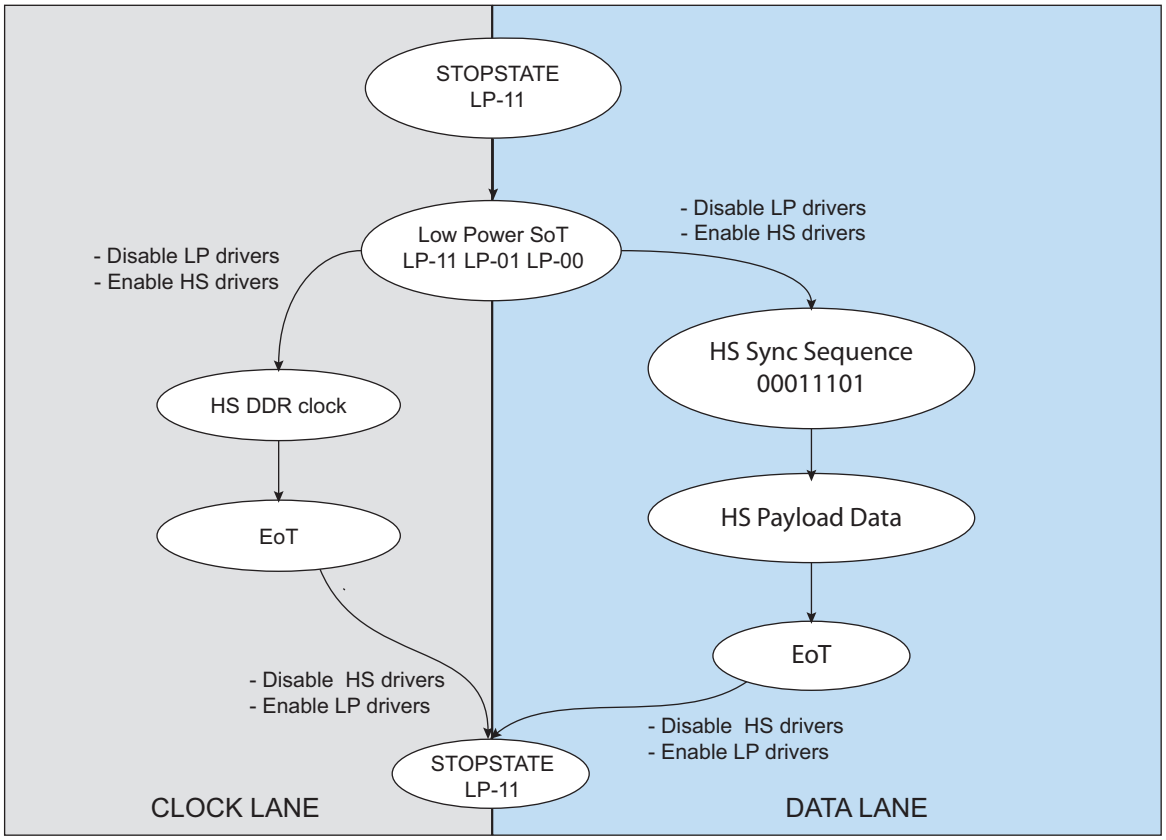
A burst contains the low-power initialization sequence, the high-speed data payload, and also the end of transmission sequence.

Figure 49.3. HS Data Transfer Sequence

High-Speed mode request is initiated by the DSI host. This request is processed differently for clock and data lanes.

© 2026 Microchip Technology Inc. and its subsidiaries

For a clock lane, the high-speed request is followed by the transmission of a low-power sequence that represents this request for the receiver side (a lane high-speed request). Only after generating this sequence, the low-power driver is disabled, and the high-speed driver enabled. After the time necessary to settle, the transmission of the high-speed DDR clock starts.



For a data lane, the high-speed request starts with a lane high-speed request and, in addition, extends the payload data with a leader and a trailer sequence that allows for the receiver synchronization. The transmission of such sequence requires the existence of a valid high-speed clock signal in the clock lane.

When the high-speed request is disabled, each lane exits High-Speed Data Transmission mode. It is important that a clock lane is in High-Speed mode during the complete high-speed data transmission state of all the lanes. The clock lane must enter High-Speed mode before a high-speed data transmission begins and it must not leave this state before all the lanes finish their respective high-speed data transmission bursts.

The operation sequence when exiting High-Speed mode is also different for data and clock lanes.

For a clock lane, high-speed transmission always ends with an HS-0 state, followed by the disabling of the high-speed driver, and enabling of the low-power driver. As for a data lane, the transmission ends with the differential state opposite to the last bit transmitted, followed by the disabling of the high-speed driver, and enabling of the low-power driver.

Figure 49.4. HS Data Transfer State Diagram

49.6.1.2.3.Escape Mode

Escape mode uses the data lanes to communicate asynchronously using the low-power states at low speed. The D-PHY supports this mode in both directions. A data lane enters Escape mode through an Escape mode entry procedure (LP-11, LP-10, LP-00, LP-01, LP-00), if an LP-11 is detected before reaching LP-00 state, the entry is aborted and the receiver returns to the Stop state. Once the

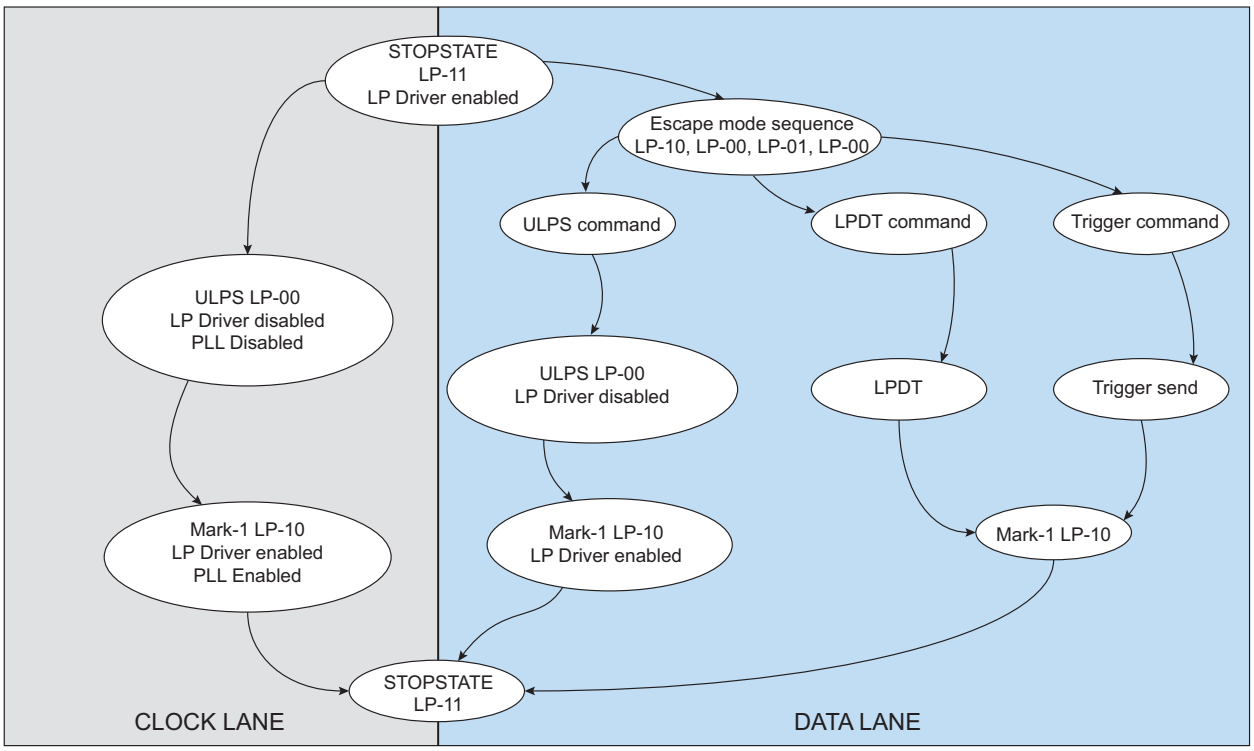
© 2026 Microchip Technology Inc. and its subsidiaries

sequence is correctly completed, the transmitter sends an 8-bit command to indicate a requested action.

If the entry command is not valid, it is ignored, the error flag ERRESC goes high (DSI_INT_ST0.DPHY_ERRORS_0), and the receiver waits until the transmitter returns to the Stop state.

The D-PHY applies Spaced-One-Hot encoding (a Mark state is interleaved with a Space state) on commands and data. Each symbol consists of the following two parts:

- One-Hot phase
- Space state



To transmit one bit, a Mark-1 should be sent followed by the Space state. In the case of a zero bit, a Mark-0 should be sent followed by the Space state.

Table 49.2. Possible Escape Mode Sequences for Data Lanes

Escape Mode Action	Entry Command Pattern (First Bit to Last Bit to be Transmitted)	Command Type
Low-Power Data Transmission	11100001	Mode
Ultra-Low-Power State	00011110	Mode
Reset Trigger	01100010	Trigger
Unknown - 3	01011101	Trigger
Unknown - 4	00100001	Trigger
Unknown - 5	10100000	Trigger

The Escape mode transition sequencing from state to state is presented in Figure 7-4.

Figure 49.5. Escape Mode Sequence State Diagram

- Low-Power Data Transmission (LPDT)

© 2026 Microchip Technology Inc. and its subsidiaries

In LPDT mode, the data can be transmitted by the protocol at low speed in Low-Power mode. High-speed drivers or receivers are off and low-power drivers or receivers are on. During LPDT, the protocol can pause by maintaining a Space state on the lines.

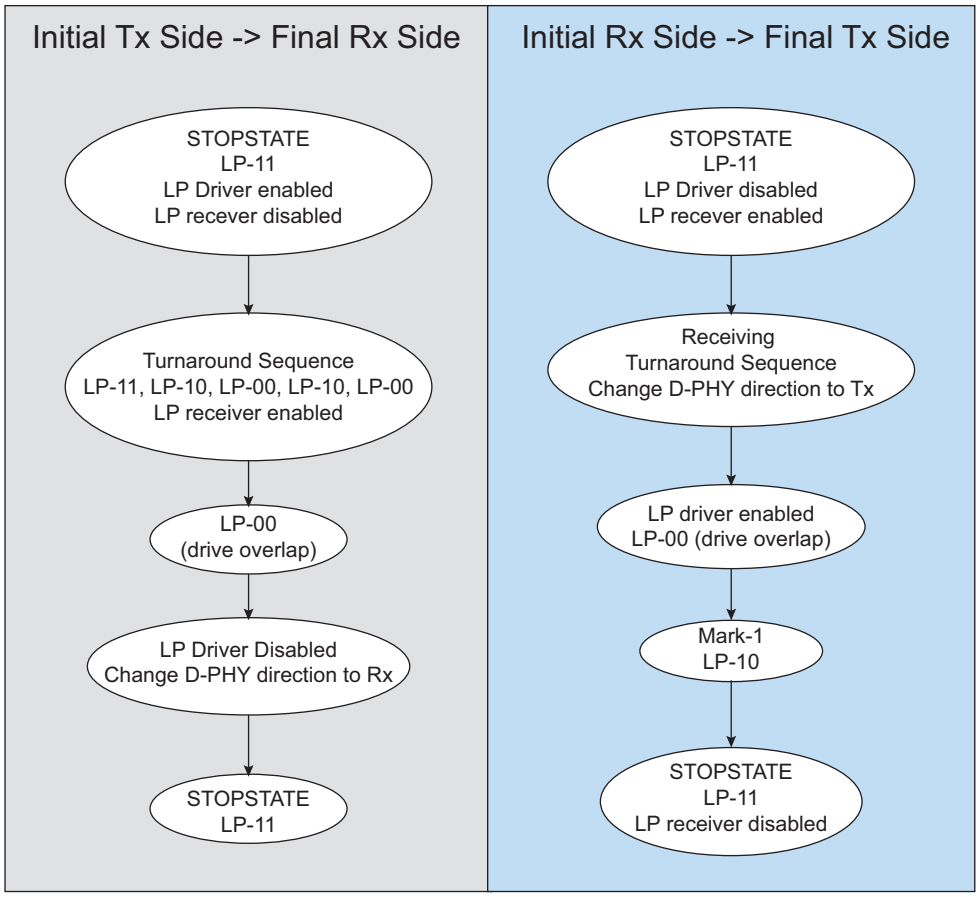
- Remote Trigger

Remote Trigger mode allows the protocol to send a flag to the receiving side, at the request of the transmitting side.

- Ultra-Low-Power State (ULPS)

Ultra-Low-Power State (ULPS) mode has the lowest power consumption, excluding Shutdown mode.

For data lanes, this mode is entered by sending an Ultra-Low-Power state entry command after the Escape mode entry command. During this mode, the lines are in the Space state (LP-00). Although the clock lane does not support regular Escape mode, the clock lane supports ULPS. If all lanes are set to ULPS, the PLL is turned off.



- Turnaround

The D-PHY allows the transmission direction of the data lanes to be swapped by means of a turnaround request. The sequence of a turnaround operation is described below:

1. Transmitter side
   a. Starts when the DSI host initiates a turnaround request, assuming the D-PHY is in Stop state
   b. The transmitter sends specific low-power sequence—LP-11, LP-10, LP-00, L-10, L-00 The turnaround operation can be disabled while in power down mode.
2. Receiver side
   a. After receiving a complete low-power sequence, the receiver enables the low-power driver.
   b. Transmits LP-00, indicating change.
   c. Overlapping LP-00 transmitted by the initial transmitter.
   d. Initial receiver side transmits LP-10, followed by LP-11, returning to Control mode.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 49.6. Turnaround Sequence State Diagram

49.6.2. D-PHY Control Operation

49.6.2.1. General D-PHY Control Operation

The D-PHY is controlled by the DSI host user interface. For any test code and data, the control operation is carried out by following the steps below:

1. Ensure that the D-PHY is in Shutdown mode. See Shutdown Mode.
2. Reset the analog configuration by generating a high pulse on PHY_TESTCLR in the D-PHY Control register 0 (DSI_DPHY_TST_CTRL0).
3. Write a '1' to DSI_DPHY_TST_CTRL0.PHY_TESTCLK.
4. Write test code to PHY_TESTDIN and write a '1' to PHY_TESTEN in the D-PHY Control register 1 (DSI_DPHY_TST_CTRL1).
5. Write a '0' to DSI_DPHY_TST_CTRL0.PHY_TESTCLK.
6. Write a '0' to DSI_DPHY_TST_CTRL1.PHY_TESTEN and write the test data value to DSI_DPHY_TST_CTRL1.PHY_TESTDIN.
7. Write a '1' to DSI_DPHY_TST_CTRL0.PHY_TESTCLK.
8. Write a '0' to DSI_DPHY_TST_CTRL0.PHY_TESTCLK.

49.6.2.2. High-Speed Frequency Range Control Operation

The high-speed frequency range (hsfreqrange) is controlled by following the generic D-PHY Control operation (see General D-PHY Control Operation), and with the test code 0x44 and the data value from the following table:

© 2026 Microchip Technology Inc. and its subsidiaries

Table 49.3. Frequency Ranges

Ranges (Mbps)	High-Speed Bit Rate Code
80-89	0000000
90-99	0100000
100-109	1000000
110-129	0000010

330-359	0101010
360-399	1001010
400-449	0001100
450-499	0101100
500-549	0001110
550-599	0101110
600-649	0010000
650-699	0110000
700-749	0010010
750-799	0110010
800-849	1010010
850-899	1110010
900-949	0010100
950-1000	0110100

49.6.2.3. D-PHY PLL Control Operation

The D-PHY includes a fully programmable PLL, enabling a flexible lane bit rate value. The generated clock frequency (f_{out}) is a function of the input reference frequency and of the multiplication and division ratios. It can be determined as follows:

$$f_{\text{out}} = \frac{M}{N} \cdot f_{\text{ref}}$$

Where:

- M = feedback multiplication ratio
- N = input frequency division ratio
- f_{ref} = frequency of the main crystal oscillator. f_{ref} = 24 MHz.

Note that the following limit applies:

$$40\text{MHz} \geq \frac{f_{\text{ref}}}{N} \geq 5\text{MHz}$$

© 2026 Microchip Technology Inc. and its subsidiaries

The PLL output clock (with frequency f_{out}) is the full-rate clock used for bit serialization. A 1000 Mbps bit rate on the data lanes assumes PLL output frequency to be equal to 1000 MHz.

The D-PHY also generates the lanebyteclk clock signal with a frequency of $f_{out}/8$.

The PLL output frequency ranges are selected from the following table:

Table 49.4. PLL Output Frequency Ranges

Ranges (Mbps)	PLL Output Frequency Range (MHz)
000	80-200
001	200-300
010	300-500
011	500-700
100	700-900
101	900-1000

Some combinations of N and M are not allowed, since they violate the limits of operation of the PLL output frequency or the minimum allowed comparison frequency. Due to the use of a “by 2 pre-scaler” the range of the feedback multiplication value M is limited to even division numbers.

To ensure proper operation of the PLL, the loop bandwidth should be configured depending on the selected frequency. The control over the Charge Pump (CP) current (ICPCTRL[3:0]), the Low-Pass Filter (LPF) characteristics (LPFCTRL[5:0]), and VCO control signals (VCORANGE and VCOCAP) is granted. The table below presents the correspondence.

Table 49.5. PLL CP and LPF Control Fields

PLL Output Frequency Range (MHz)	VCORANGE	ICPCTRL	LPFCTRL	VCOCAP
80-110	000	0100	010000	00
110-150		1000	001000	00
150-200		1100	001000	00
200-250	001	1100	001000	00

500-600	011	0110	010000	00
600-700		0110	000100	00
700-900	100	0110	000100	00
900-1000	101	0111	010000	00

To configure D-PHY PLL, follow the steps below in conjunction with the procedure in General D-PHY Control Operation:

1. Configure the VCO parameters with the test code 0x10 and data as follows:
   - Bit 7:
     0: VCO range is programmed with the default values for the corresponding hsfreqrange
     1: VCO range is programmed with bits 5:3
   - Bit 6: Reserved
   - Bits 5:3: VCO range control (vcorange)
   - Bits 2:1: VCO internal capacitance control (vcocap)
     00: Default capacitance
     01: Low capacitance (four times lower than the default value)
     10: High capacitance (double the default value)

© 2026 Microchip Technology Inc. and its subsidiaries

11: Not allowed

- Bit 0: Reserved

2. Configure PLL Control with test code 0x11 and data icpctrl.
3. Configure PLL Control with test code 0x12 and data as follows:
   - Bit 7: Bypass CP default values
     0: vcocap is programmed with the default values for the corresponding hsfreqrange
     1: vcocap is programmed with bits 3:0 using test code 0x11
   - Bit 6: Bypass LPF default values
     0: LPF is programmed with the default values for the corresponding hsfreqrange
     1: LPF is programmed with bits 5:0
   - Bit 5:0: Loop filter control (lpfctrl)
     000000: Loop Filter resistor is 18kΩ
     000001: Loop Filter resistor is 15.6kΩ
     000010: Loop Filter resistor is 15kΩ
     000100: Loop Filter resistor is 14.4kΩ
     001000: Loop Filter resistor is 12.8kΩ
     010000: Loop Filter resistor is 11.4kΩ
     100000: Loop Filter resistor is 10.5kΩ
4. Enable N and M values with test code 0x19 and data as follows:
   - Bits 7:6: Reserved
   - Bit 5: Bypass the PLL loop divider default values
     0: PLL loop divider is programmed with the default values for the corresponding hsfreqrange
     1: PLL loop divider is programmed using the test code 8'h18 (PLL Loop Divider Ratio)
   - Bit 4: Bypass PLL input divider default values
     0: PLL input divider is programmed with the default values for the corresponding hsfreqrange
     1: PLL input divider is programmed using test code 8'h17 (PLL Input Divider Ratio)
   - Bits 3:0: Reserved
5. Configure PLL Input Divider Ratio (N) with test code 0x17 and data assigned to N-1
6. Configure PLL Loop Divider Ratio (M) with test code 0x18 and data as follows:
   For m = M-1:
   - Data bit 7: Bit Field Selector
     - When data bit 7 is 0, LSBs are accessed:
       - data bits 6:5: Reserved
       - data bits 4:0: m[4:0]
     - When data bit 7 is 1 : MSBs are accessed:
       - data bits 6:4: Reserved
       - data bits 3:0: m[8:5]

49.6.3. Input Video Interface

49.6.3.1. Initialization

The Input Video interface captures the data and control signals from the LCD Controller (LCDC) and conveys them to the FIFO interfaces that transmit them to the DSI link. Two different streams of data are presented at the interface; video control signals and pixel data.

© 2026 Microchip Technology Inc. and its subsidiaries

Depending on the interface color coding, the pixel data is disposed differently throughout the bus. Interface pixel color coding is shown in the table below:

Table 49.6. Location and Color Component In Input Video Interface

Order	16-bit Config 1	16-bit Config 2	16-bit Config 3	18-bit Config 1	18-bit Config 2	24-bit	DSC24

D1	B[1]	B[1]	B[0]	B[1]	B[1]	B[1]	Byte3[1]
D0	B[0]	B[0]	–	B[0]	B[0]	B[0]	Byte3[0]

These configuration options are as follows:

- Polarity control: All the control signals are programmable to change the polarity depending on the LCDC configuration.
- After the controller reset, the input video interface waits for the first VSYNC active transition to start signal sampling, including pixel data, thus avoiding starting the transmission of the image data in the middle of a frame.
- If the interface pixel color coding is 18 bits and the 18-bit loosely packed stream is disabled, the number of pixels programmed in the field VID_PKT_SIZE in the Video Mode Packet Size Configuration register (DSI_VID_PKT_SIZE) must be a multiple of four. This means that in this mode, the two LSBs in the configuration are always inferred as zero. The specification states that in this mode, the pixel line size should be a multiple of four.
- To avoid FIFO underflows and overflows, the configured number of pixels is assumed to be received at all times. A set of bits in the DSI_VID_PKT_STATUS register report the status of the FIFOs and internal buffers associated with the input video interface support.
- To keep the memory organized with respect to the packet scheduling, the number of pixels per packet parameter is used to separate the memory space of different video packets.

For Shutdown and Color mode signal transmission, the input video signaling must be active. Because of such constraints and for commands to be correctly transmitted, the first VSYNC active pulse should occur for command sampling and transmission. When shutting down the display, the

© 2026 Microchip Technology Inc. and its subsidiaries

input video must remain active for one frame after the command has been issued. This ensures that the commands are correctly transmitted before disabling the video generation at the input video interface.

49.6.3.2. Video Transmission Modes

The different video transmission modes are as follows:

- Burst mode
- Non-Burst mode
  - Non-Burst mode with sync pulse
  - Non-Burst mode with sync event

49.6.3.2.1. Burst Mode

In this mode, the entire active pixel line is buffered into a FIFO and transmitted in a single packet with no interruptions. This transmission mode requires that the Input Video Pixel FIFO has the capacity to store a full line of active pixel data. This mode is optimized if the difference between the pixel required bandwidth and DSI link bandwidth is very different. This enables the DSI host to quickly dispatch the entire active video line in a single burst of data and then return to Low-Power mode.

49.6.3.2.2. Non-Burst Mode

In this mode, the processor uses the partitioning properties of the DSI host to divide the video line transmission into several DSI packets. This is done to match the pixel required bandwidth with the DSI link bandwidth. With this mode, the controller configuration does not require a full line of pixel data to be stored inside the input video pixel FIFO. It requires only the content of one video packet.

49.6.3.3. Updating the Input Video Interface Configuration

It is possible to update the Input Video Interface configuration on the fly without impacting the current frame. Using the Video Mode Shadow Feature Control register (DSI_VID_SHADOW_CTRL). The new configuration is only used when the system requests it.

To update the input video interface configuration during the transmission of a video frame, the configuration of that frame must be stored in the auxiliary registers. Thus, the new frame configurations can be set through the user interface without corrupting the current frame.

By default, this feature is disabled. To enable this feature, set the bit DSI_VID_SHADOW_CTRL.VID_SHADOW_EN to ‘1’. When this feature is enabled, the system supplies the configuration stored in the auxiliary registers.

If the active registers must be updated immediately without the reset, ensure that the bits DSI_VID_SHADOW_CTRL.VID_SHADOW_EN and DSI_VID_SHADOW_CTRL.VID_SHADOW_REQ are set to 0.

49.6.4. Generic Interface

49.6.4.1. Description

The user interface allows the transmission of write and read command mode packets. Commands sent through this interface are not limited to the scope of the DCS specification, and can include generic commands described in the DSI specification as manufacturer-specific.

The Generic Interface Payload register (DSI_GEN_PLD_DATA) has two distinct functions based on the operation. Writing to this register sends the data as payload when sending a Command mode packet. Reading this register returns the payload of a read back operation. The Generic Interface Header register (DSI_GEN_HDR) contains the Command mode packet header type and header data. Writing to this register triggers the transmission of the packet implying that for a long Command mode packet, the packet payload must be written in advance in DSI_GEN_PLD_DATA.

The valid packets available to be transmitted through the generic interface are as follows:

© 2026 Microchip Technology Inc. and its subsidiaries

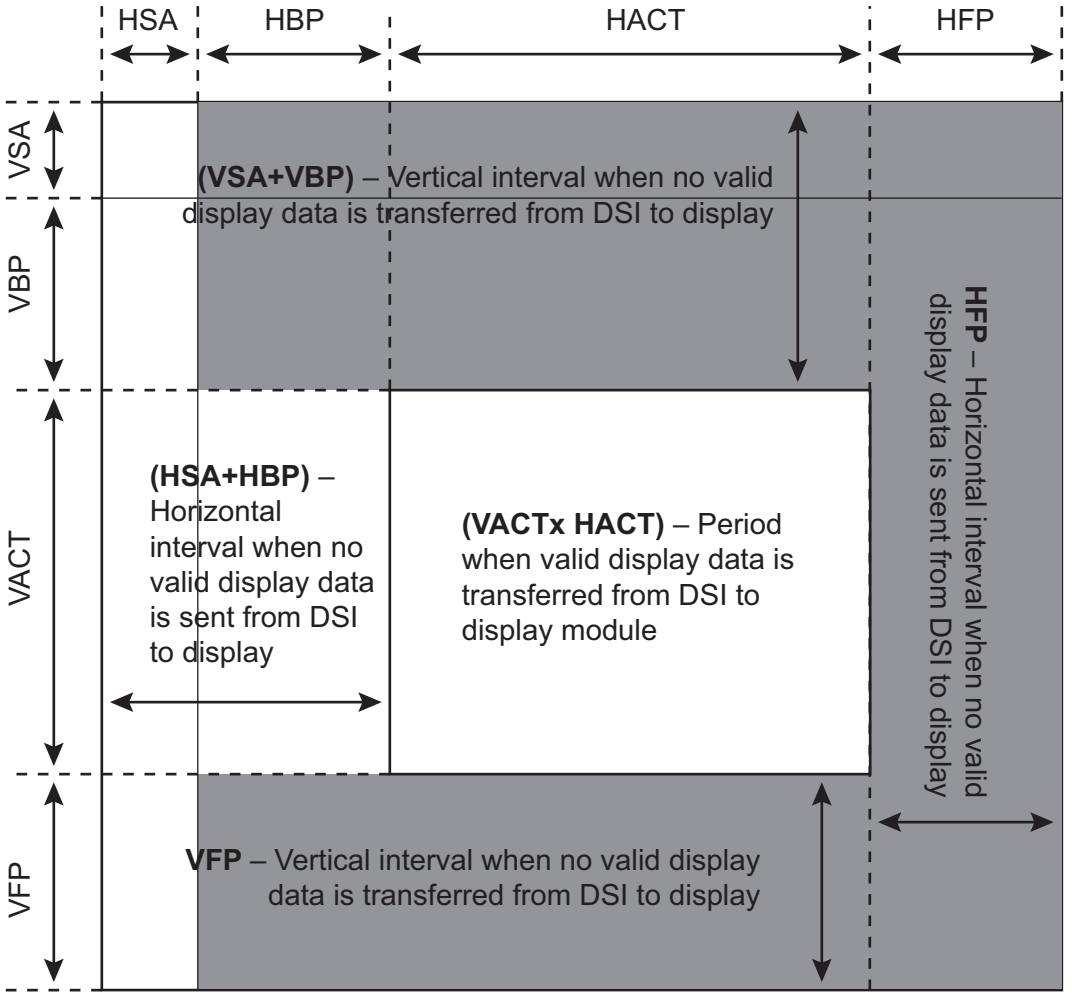
- Generic Write Short Packet 0 Parameters
- Generic Write Short Packet 1 Parameters
- Generic Write Short Packet 2 Parameters
- Generic Read Short Packet 0 Parameters
- Generic Read Short Packet 1 Parameters
- Generic Read Short Packet 2 Parameters
- Maximum Read Packet Configuration
- Generic Long Write Packet
- DCS Write Short Packet 0 Parameters
- DCS Write Short Packet 1 Parameters
- DCS Read Short Packet 0 Parameters
- DCS Write Long Packet

A set of bits in the Command Packet Status register (DSI_CMD_PKT_STATUS) reports the status of the FIFOs associated with user interface support.

49.6.4.2. Packet Transmission Using the Generic Interface

While writing the packet information, first write the payload of a given packet into the payload FIFO using DSI_GEN_PLD_DATA. When the payload data is for the command parameters, place the first byte to be transmitted in the least significant byte position of the user interface data bus. For more information, see Generic Interface Payload Register.

After writing the payload, write the packet header into the command FIFO. For more information about the packet header organization on the user interface, see Generic Interface Header Register.



49.6.5. Transmission of Commands

49.6.5.1. Transmission of Commands in Video Mode

The DSI host supports the transmission of commands, both in high-speed and low-power, while in Video mode. Vertical and horizontal porch periods are used to transmit commands inserted through the user interface. Those periods correspond to the shaded areas of the figure below:

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 49.7. Command Transmission Periods within the Image Area

Commands are transmitted in the blanking periods after the following packets/states:

- Vertical Sync Start (VSS) packets, if the video sync pulses are not enabled
- Horizontal Sync End (HSE) packets, in the VSA, VBP, and VFP regions
- Horizontal Sync Start (HSS) packets, if the video sync pulses are not enabled in the VSA, VBP, and VFP regions
- Horizontal Active (HACT) state

The DSI host does not send commands in the last line unless a command does not fit into any blanking period area. In this case, it is postponed to the last line, causing the violation of the line time for Video mode.

There can be only one command sent in Low-Power mode per line. However, one Low-Power mode command is possible for each line.

In high-speed, the DSI host can send more than one command and as many as the host determines can fit in the available time.

The Color Mode and Shutdown signals controlled by the LCDC are also able to trigger the transmission of command packets. For details, refer to the section LCD Controller (LCDC). The commands are DSI data types Color Mode On, Color Mode Off, Shut Down Peripheral, and Turn On Peripheral. These commands are not sent in the VACT region. If the bit LP_CMD_EN in the Video Mode Configuration register (DSI_VID_MODE_CFG) is 1, these commands are sent in LP mode. In

© 2026 Microchip Technology Inc. and its subsidiaries

LP mode, the field OUTVACT_LPCMD_TIME in the Input Video Timing for Low-Power Commands Configuration register (DSI_DPI_LP_CMD_TIM) is used to determine if these commands can be transmitted. It is assumed that DSI_DPI_LP_CMD_TIM.OUTVACT_LPCMD_TIME is greater than or equal to four bytes (number of bytes in a short packet).

If DSI_VID_MODE_CFG.FRAME_BTA_ACK_EN is set to 1, a Bus Turn-Around (BTA) is generated by the DSI host after the last line of a frame. This may coincide with a write command or a read command.

49.6.5.2. Transmission of Commands in Low-Power

The DSI host can be configured to send the low-power (LP) commands during the HS video mode transmission. To enable this feature, set the bit DSI_VID_MODE_CFG.LP_CMD_EN to 1. In this case, it is necessary to ensure there is enough time available, in bytes, to transmit a command in LP mode to Horizontal Front Porch (HFP), Vertical Sync Active (VSA), Vertical Back Porch (VBP), and Vertical Front Porch (VFP) regions. Bits 8 to 13 of DSI_VID_MODE_CFG indicate whether the DSI host can go to low-power depending on the current image area.

If DSI_VID_MODE_CFG.LP_CMD_EN is set to 1 and non-video packets are in the queue, the DSI host ignores the Low-Power mode configuration and transmits Low-Power mode commands, even if it is not allowed to enter Low-Power mode in a specific region. After transmitting Low-Power mode commands, the DSI host remains in Low-Power mode until a sync event occurs.

49.6.5.3. Transmission of Commands in High-Speed

If DSI_VID_MODE_CFG.LP_CMD_EN is set to 0, the commands are sent in high-speed in Video mode. In this case, the DSI host automatically determines the area where each command can be sent and no programming or calculation is required.

49.6.5.4. Read Command Transmission

The DSI_PHY_TMR_CFG.MAX_RD_TIME configures the maximum amount of time required to perform a read command in lane byte clock cycles. It is calculated as follows:

MaxRdTime = Time to transmit the read command in LP mode + Time to enter and leave LP mode + Time to return the read data packet from the peripheral device.

The time to return the read data packet from the peripheral depends on the number of bytes read and the escape clock frequency of the peripheral. The field MAX_RD_TIME is used in both High-Speed and Low-Power modes to determine if there is time to complete a read command in a blanking period.

In High-Speed mode (DSI_VID_MODE_CFG.LP_CMD_EN = 0), MaxRdTime is calculated as follows:

$$\text{MaxRdTime} = \frac{t_{\text{HS}\rightarrow\text{LP}} + t_{\text{LP}\rightarrow\text{HS}} + t_{\text{read}} + 2t_{\text{BTA}}}{\text{lanebyteclkperiod}}$$

In Low-Power mode (DSI_VID_MODE_CFG.LP_CMD_EN = 1), MaxRdTime is calculated as follows:

$$\text{MaxRdTime} = \frac{t_{\text{HS}\rightarrow\text{LP}} + t_{\text{LP}\rightarrow\text{HS}} + t_{\text{lpdt}} + t_{\text{lprd}} + t_{\text{read}} + 2t_{\text{BTA}}}{\text{lanebyteclkperiod}}$$

Where:

- $t_{HS->LP}$ = Time to enter LP mode
- $t_{LP->HS}$ = Time to leave LP mode
- t_{LPDT} = D-PHY timing related to Escape mode entry, LPDT command, and Escape mode exit. This value is always 11 bits in Low-Power mode (or 22 TX escape clock cycles).
- t_{lprd} = Read command time in LP mode (64 * TX escape clock)
- t_{read} = Time to return the read data packet from the peripheral
- t_{BTA} = time to perform a bus turnaround (device D-PHY dependent)

It is recommended to keep the maximum number of bytes read from the peripheral to a minimum to have sufficient time available to issue the read commands in a line time.

© 2026 Microchip Technology Inc. and its subsidiaries

49.6.5.5. Clock Lane in Low-Power Mode

To reduce the power consumption of the D-PHY, the DSI host, when not transmitting in High-Speed mode, allows the clock lane to enter Low-Power mode. The controller automatically handles the transition of the clock lane from High-Speed mode (Clock lane active sending clock) to Low-Power mode without direct intervention by the software. This feature can be enabled by configuring the bits PHY_TXREQUESTCLKHS and AUTO_CLKLANE_CTRL in the Clock Lane Control register (DSI_LPCLK_CTRL).

In Command mode, the DSI host can place the clock lane in Low-Power mode when it does not have any High-speed packets to transmit. In Video mode, the Low-Power mode controller uses its internal video and D-PHY timing configurations to determine if there is time available for the clock line to enter Low-Power mode and not compromise the video data transmission of pixel data and sync events.

Along with a correct configuration of Video mode, the DSI host needs to know the time required by the clock and data lanes to go from high-speed to low-power and from low-power to high-speed. The values required can be obtained from the following table. Program the Clock Lane Switch Mode Timing Configuration register (DSI_DPHY_TMR_LPCLK_CFG) and the Data Lane Switch Mode Timing Configuration register (DSI_DPHY_TMR_CFG) with the following values expressed in lane byte clock periods:

Table 49.7. High-Speed Transition Times (expressed in lane byte clock periods)

Frequency Range (MHz)	LP->HS Clock Lane	HS->LP Clock Lane	LP->HS Data Lane	HS->LP Data Lane
80-89	32	20	26	13
90-99	35	23	28	14
100-109	32	22	26	13
110-129	31	20	27	13
130-139	33	22	26	14

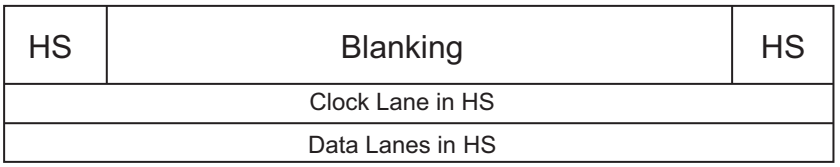
450-499	73	31	59	22
500-549	79	36	63	24
550-599	83	37	68	25
600-649	90	38	73	27
650-699	95	40	77	28
700-749	102	40	84	28
750-799	106	42	87	30
800-849	113	44	93	31
850-899	118	47	98	32

© 2026 Microchip Technology Inc. and its subsidiaries

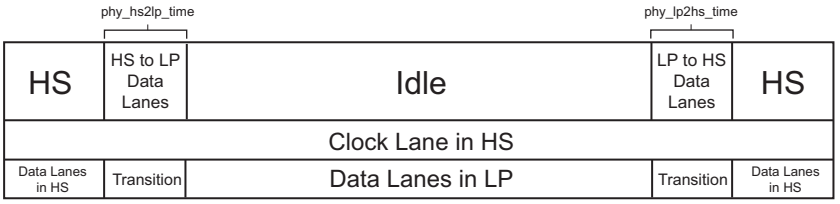
Table 49.7. High-Speed Transition Times (expressed in lane byte clock periods) (continued)



Frequency Range (MHz)	LP->HS Clock Lane	HS->LP Clock Lane	LP->HS Data Lane	HS->LP Data Lane
900-949	124	47	102	34
950-999	130	49	107	35

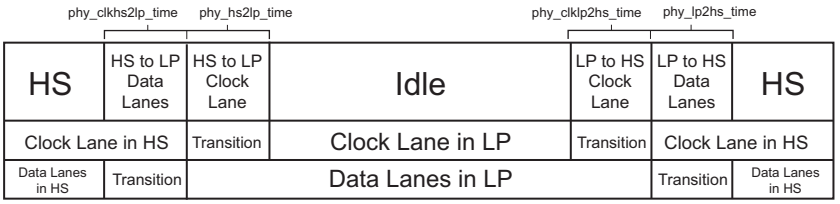
Based on the programmed values, the DSI host calculates if there is enough time for the clock lane to enter Low-Power mode during inactive regions of the video frame. There is an exception where the clock lane is activated even when there is no high-speed packet required to be transmitted. If a command is not allowed to be transmitted in any of the available blanking periods, it is transmitted during the last line of the frame.

The DSI host determines the best approach regarding power saving from among the following three possible cases:



- There is not sufficient time to enter Low-Power mode. Therefore, a blanking period is added.

Figure 49.8. Clock Lane and Data Lanes in High-Speed mode (HS)



- There is sufficient time for the data lanes to enter Low-Power mode but not enough time for the clock lane to enter Low-Power mode.

Figure 49.9. Clock Lane in High-Speed (HS) and Data Lanes in Low-Power Mode (LP)

- There is sufficient time for both data lanes and the clock lane to enter Low-Power mode.

Figure 49.10. Clock Lane and Data Lanes in Low-Power Mode (LP)

49.6.6. Video Mode Pattern Generator

The Video mode pattern generator allows the transmission of horizontal/vertical color bars and D-PHY BER testing patterns without any stimuli. The frame requirements must be defined in the video registers listed below:

- DSI_VID_MODE_CFG
- DSI_VID_PKT_SIZE
- DSI_VID_NUM_CHUNKS
- DSI_VID_NULL_SIZE

© 2026 Microchip Technology Inc. and its subsidiaries

- DSI_VID_HSA_TIME
- DSI_VID_HBP_TIME
- DSI_VID_HLINE_TIME
- DSI_VID_VSA_LINES
- DSI_VID_VBP_LINES
- DSI_VID_VFP_LINES
- DSI_VID_VACTIVE_LINES

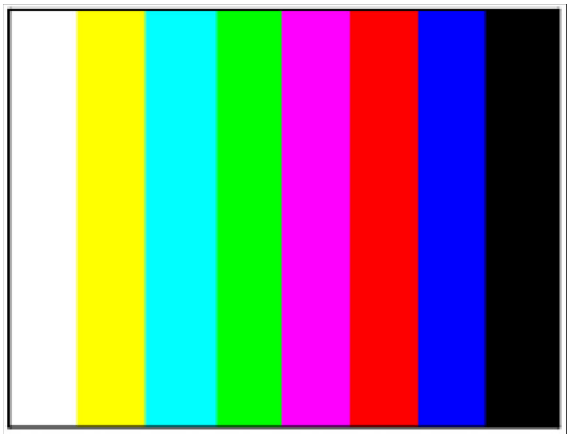
Refer to the Register Summary for additional information.

49.6.6.1. Color Bar Pattern

The color bar pattern comprises eight bars of the colors white, yellow, cyan, green, magenta, red, blue, and black.

Each color width is calculated by dividing the line pixel size (vertical pattern) or the number of lines (horizontal pattern) by eight. In Vertical Color Bar mode, each single color bar has a width equal to the number of pixels in a line divided by eight. If the number of pixels in a line is not divisible by eight, the last color (black) contains the remaining pixels. In Horizontal Color Bar mode, each color line has a width equal to the number of lines in a frame divided by eight. If the number of lines in a frame is not divisible by eight, the last color (black) contains the remaining lines.

Figure 49.11. Vertical Color Bar Mode



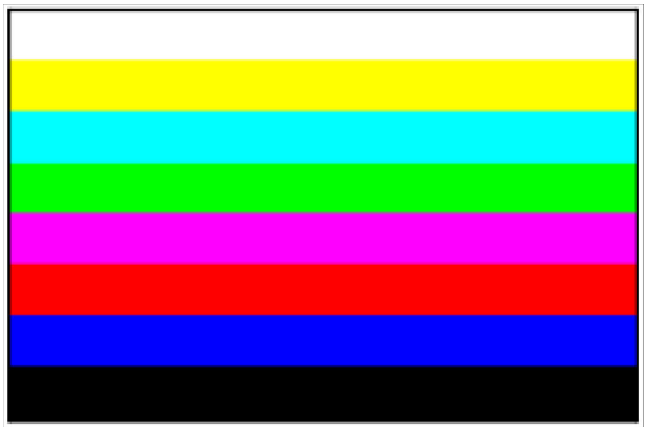


Figure 49.12. Horizontal Color Bar Mode

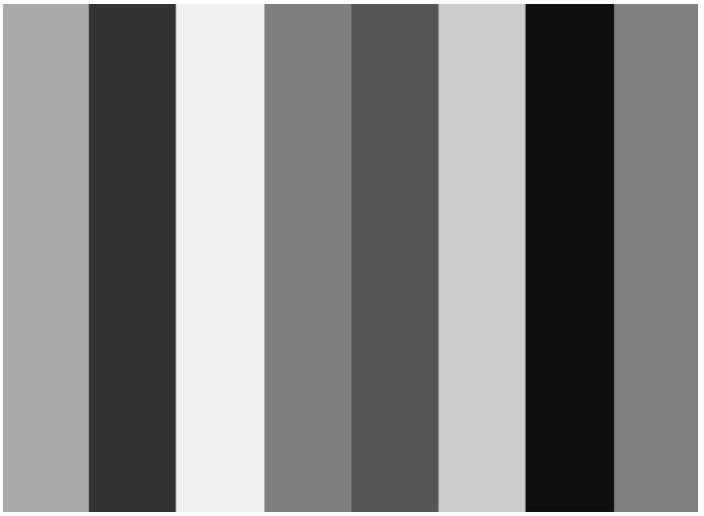
© 2026 Microchip Technology Inc. and its subsidiaries



49.6.6.2. BER Testing Pattern

The BER testing pattern simplifies conformance testing. This pattern tests the RX D-PHY capability to receive the data correctly. The following data patterns are required:

- X bytes of 0xAA (high-frequency pattern, inverted)
- X bytes of 0x33 (mid-frequency pattern)
- X bytes of 0xF0 (low-frequency pattern, inverted)
- X bytes of 0x7F (lone 0 pattern)
- X bytes of 0x55 (high-frequency pattern)
- X bytes of 0xCC (mid-frequency pattern, inverted)
- X bytes of 0x0F (low-frequency pattern)
- Y bytes of 0x80 (lone 1 pattern)

In most cases, Y is equal to X. However, depending on line length and the color coding used, Y may be a different value than X. With RGB888 color coding and horizontal resolution in multiples of eight, the following pattern appears on the DSI display:

Figure 49.13. RGB888 BER Testing Pattern

Depending on the orientation, BER mode, and color coding, the smallest resolutions accepted by the video mode pattern generator are:

- BER mode: 8x8
- Horizontal color bar mode: 8x8
- Vertical color bar mode: 8x8

49.6.7. Error Handling

The interrupts triggered by the Interrupt Status registers 0 and 1 (DSI_INT_ST0 and DSI_INT_ST1) are error conditions.

The two following tables provide the causes that trigger these interrupts and also explain how to recover from them.

© 2026 Microchip Technology Inc. and its subsidiaries

Table 49.8. Error Cause and Recovery for INT_ST0 Register

Bit	Name	Cause of the Error	Recommended Method of Handling the Error
20	DPHY_ERRORS_4	The D-PHY reports the LP1 contention error. The D-PHY host detects the contention while trying to drive the line high.	Recover the D-PHYs from contention. Reset the DSI host and transmit the packets again. If this error is recurrent, analyze the connectivity between the host and the device carefully.
19	DPHY_ERRORS_3	D-PHY reports the LP0 contention error. The D-PHY host detects the contention while trying to drive the line low.	Recover the D-PHYs from contention. Reset the DSI host and transmit the packets again. If this error is recurrent, analyze the connectivity between the host and the device carefully.
18	DPHY_ERRORS_2	The D-PHY reports the False Control Error. The D-PHY detects an incorrect line state sequence in lane 0 lines.	Device does not behave as expected. Communication with the device is not properly established. This is an unrecoverable error. Reset the DSI host and the D-PHY. If this error is recurrent, analyze the behavior of the device.
17	DPHY_ERRORS_1	The D-PHY reports the LPDT Error. The D-PHY detects that the LDPT did not match a multiple of 8 bits.	The data reception is not reliable. The D-PHY recovers but the received data from the device might not be reliable. It is recommended to reset the DSI host and repeat the RX transmission.
16	DPHY_ERRORS_0	The D-PHY reports the Escape Entry Error. The D-PHY does not recognize the received Escape Entry Code.	The D-PHY does not recognize the Escape Entry Code. The Transmission is ignored. The D-PHY host recovers but the system should repeat the RX reception.
15	ACK_WITH_ERR_15	This error is directly retrieved from Acknowledge with Error packet. The device detected a protocol violation in the reception.	Refer to the display documentation. When this error is active, the device should have another read-back command that reports additional information about this error. Read the additional information and take appropriate actions.
14	ACK_WITH_ERR_14	The Acknowledge with Error packet contains this error. The device chooses to use this bit for error report.	Refer to the device documentation regarding possible reasons for this error and take appropriate actions.
13	ACK_WITH_ERR_13	The Acknowledge with Error packet contains this error. The device reports that the transmission length does not match the packet length.	Possible reason for this is multiple errors present in the packet header (more than 2), so the error detection fails and the device does not discard the packet. In this case, the packet header is corrupt and can cause decoding mismatches. Transmit the packets again. If this error is recurrent, analyze the connectivity between the host and the device carefully.
12	ACK_WITH_ERR_12	The Acknowledge with Error packet contains this error. The device does not recognize the VC ID in at least one of the received packets.	Check the device capabilities and configure the host to properly address the device VC ID. Repeat the transmission.
11	ACK_WITH_ERR_11	The Acknowledge with Error packet contains this error. The device does not recognize the data type of at least one of the received packets.	Check the device capabilities. It is possible that there are some packets that are not supported by the device. Repeat the transmission.
10	ACK_WITH_ERR_10	The Acknowledge with Error packet contains this error. The device detects the CRC errors in at least one of the received packets.	Some of the long packets, transmitted after the last Acknowledge request, might contain the CRC errors in the payload. If the payload content is critical, transmit the packets again. If this error is recurrent, analyze the connectivity between the host and the device carefully.
9	ACK_WITH_ERR_9	The Acknowledge with Error packet contains this error. The device detects multi-bit ECC errors in at least one of the received packets.	The device does not interpret the packets transmitted after the last Acknowledge request. If the packets are critical, transmit the packets again. If this error is recurrent, analyze the connectivity between the host and the device carefully.
8	ACK_WITH_ERR_8	The Acknowledge with Error packet contains this error. The device detects and corrects the 1 bit ECC error in at least one of the received packets	No action is required. The device acknowledges the packet. If this error is recurrent, analyze the signal integrity or the noise conditions of the link.

Table 49.8. Error Cause and Recovery for INT_ST0 Register (continued)

Bit	Name	Cause of the Error	Recommended Method of Handling the Error
7	ACK_WITH_ERR_7	The Acknowledge with Error packet contains this error. The device detects the Line Contention through LP0/LP1 detection.	This error might corrupt the low-power data reception and transmission. Ignore the packets and transmit them again. The device recovers automatically. If this error is recurrent, check the device capabilities and the connectivity between the host and device.
6	ACK_WITH_ERR_6	The Acknowledge with Error packet contains this error. The device detects the False Control Error.	The device detects one of the following: • The LP-10 (LP request) is not followed by the remainder of a valid escape or turnaround sequence. • The LP-01 (HS request) is not followed by a bridge state (LP-00). The D-PHY communications are corrupted. This error is unrecoverable. Reset the DSI host and the D-PHY.
5	ACK_WITH_ERR_5	The Acknowledge with Error packet contains this error. The display timeout counters for a HS reception and LP transmission expire.	It is possible that the host and device timeout counters are not correctly configured. The device HS_TX timeout should be shorter than the host HS_RX timeout. Host LP_RX timeout should be longer than the device LP_TX timeout. Check and confirm that the host configuration is consistent with the device specifications. This error is automatically recovered, although there is no guarantee that all the packets in the transmission or reception are complete.
4	ACK_WITH_ERR_4	The Acknowledge with Error packet contains this error. The device reports that the LPDT is not aligned in an 8-bit boundary	There is no guarantee that the device properly receives the packets. Transmit the packets again.
3	ACK_WITH_ERR_3	The Acknowledge with Error packet contains this error. The device does not recognize the Escape Mode Entry command.	The device does not recognize the Escape Mode Entry code. Check the device capability. Repeat the transmission to the device.
2	ACK_WITH_ERR_2	The Acknowledge with Error packet contains this error. The device detects the HS transmission did not end in an 8-bit boundary when the EoT sequence is detected.	There is no guarantee that the device properly received the packets. Re-transmission should be performed. Transmit the packets again.
1	ACK_WITH_ERR_1	The Acknowledge with Error packet contains this error. The device detects that the SoT leader sequence is corrupted.	The device discards the incoming transmission. Re-transmission should be performed by the host.
0	ACK_WITH_ERR_0	The Acknowledge with Error packet contains this error. The device reports that the SoT sequence is received with errors but synchronization can still be achieved.	The device is tolerant to single bit and some multi-bit errors in the SoT sequence. Yet, the packet correctness is compromised. If the packet content was important, transmit the packets again.

Table 49.9. Error Cause and Recovery for INT_ST1 Register

Bit	NAME	Cause of the Error	Recommended Method of Handling the Error
12	GEN_PLD_RECV_ERR	An overflow occurs in the Generic read FIFO.	The Read FIFO size is not correctly dimensioned for the maximum read-back packet size. Configure the device to return the read data with a suitable size for the host dimensioned FIFO. Data stored in the FIFOs is corrupted. Reset the DSI host and repeat the read procedure.
11	GEN_PLD_RD_ERR	An underflow occurs in the Generic read FIFO.	System does not wait for the read procedure to end and starts retrieving the data from the FIFO. The read data is requested before it is fully received. Data is corrupted. Reset the DSI host and repeat the read procedure. Check that the read procedure is completed before reading the data through the User interface.

© 2026 Microchip Technology Inc. and its subsidiaries

Table 49.9. Error Cause and Recovery for INT_ST1 Register (continued)

Bit	NAME	Cause of the Error	Recommended Method of Handling the Error
10	GEN_PLD_SEND_ERR	An underflow occurs in the Generic write payload FIFO.	The system writes the packet header before the respective packet payload is completely loaded into the payload FIFO. This error is unrecoverable, the transmitted packet is corrupted. Reset the DSI host and repeat the write procedure.
9	GEN_PLD_WR_ERR	An overflow occurs in the Generic write payload FIFO.	The payload FIFO size is not correctly dimensioned to store the total payload of a long packet. Data stored in the FIFOs is corrupted. Reset the DSI host and repeat the write procedure.
8	GEN_CMD_WR_ERR	An overflow occurs in the Generic command FIFO.	The command FIFO size is not correctly dimensioned to store the total headers of a burst of packets. Data stored in the FIFOs is corrupted. Reset the DSI host and repeat the write procedure.
7	DPI_PLD_WR_ERR	An overflow occurs in the DPI pixel payload FIFO.	The controller FIFO dimensions are not correctly set up for the operating resolution. Check the Video Mode configuration registers. They should be consistent with the LCDC video resolution. The pixel data sequence is corrupted. Reset the DSI host and re-initiate the Video transmission.
6	EOPT_ERR	Host receives a transmission that does not end with an End of Transmission packet.	This error is not critical for the data integrity of the received packets. Check if the device supports the transmission of EoTp packets.
5	PKT_SIZE_ERR	Host receives a transmission that does not end in the expected by boundaries.	The integrity of the received data cannot be guaranteed. Reset the DSI host and repeat the read procedure.
4	CRC_ERR	Host reports that a received long packet has a CRC error in its payload.	The received payload data is corrupted. Reset the DSI host and repeat the read procedure. If this error is recurrent, check the DSI connectivity link for the noise levels.
3	ECC_MULTI_ERR	Host reports that a received packet contains multiple ECC errors.	The received packet is corrupted. The DSI host ignores all the following packets. The DSI host should repeat the read procedure.
2	ECC_SINGLE_ERR	Host reports that a received packet contains a single bit error.	This error is not critical because the DSI host can correct the error and properly decode the packet. If this error is recurrent, check the DSI connectivity link for signal integrity and noise levels.
1	TO_LP_RX	Host reports that the configured timeout counter for the low-power reception has expired.	Once the configured timeout counter ends, the DSI host automatically resets the controller side and recovers to normal operation. Packet transmissions happening during this event are lost. If this error is recurrent, check the timer configuration for any issue. This timer should be greater than the maximum low-power transmission generated by the device.
0	TO_HS_TX	Host reports that the configured timeout counter for the high-speed transmission has expired.	Once the configured timeout counter ends, the DSI host automatically resets the controller side and recovers to normal operation. Packet transmissions happening during this event are lost. If this error is recurrent, check the timer configuration for any issue. This timer should be greater than the maximum high-speed transmission bursts generated by the host.

Reset	0	0	0	0	0	0	0	0

Bits 15:8 – TO_CLK_DIVISION[7:0] Timeout Clock Division
Indicates the division factor for the timeout clock used as the timing unit in the configuration of HS to LP and LP to HS transition error.

Bits 7:0 – TX_ESC_CLK_DIVISION[7:0] Transmission Escape Clock Division
Indicates the division factor for the TX Escape clock source (lanebyteclk). The values 0 and 1 stop the TX_ESC clock generation.

Reset			0	0	0	0	0	0

Bit 5 – EOTP_TX_LP_EN End Of Transmission Packet Low Power Enable

Value	Description
0	Disables the EoTp transmission in low power.
1	Enables the EoTp transmission in low power.

Bit 4 – CRC_RX_EN CRC Reception Enable

Value	Description
0	Disables the CRC reception and error reporting.
1	Enables the CRC reception and error reporting.

Bit 3 – ECC_RX_EN ECC Reception Enable

Value	Description
0	Disables the ECC reception, error correction, and reporting.
1	Enables the ECC reception, error correction, and reporting.

Bit 2 – BTA_EN Bus Turn-Around Enable

Value	Description
0	Disables the Bus Turnaround (BTA) request.
1	Enables the Bus Turnaround (BTA) request.

Bit 1 – EOTP_RX_EN End Of Reception Packet Enable

Value	Description
0	Disables the EoTp reception.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	Enables the EoTp reception.

Bit 0 – EOTP_TX_EN End Of Transmission Packet Enable

Value	Description
0	Disables the EoTp transmission.
1	Enables the EoTp transmission.

Bits 17:16 – GEN_VCID_TX_AUTO[1:0] Generic Transmission Virtual Channel Identifier
Indicates the generic interface virtual channel identification where the generic packet is automatically generated and transmitted.

Bits 9:8 – GEN_VCID_TEAR_AUTO[1:0] Generic Tearing Effect Virtual Channel Identifier
Indicates the virtual channel identification for tear effect by hardware.

Bits 1:0 – GEN_VCID_RX[1:0] Generic Reception Virtual Channel Identifier
Indicates the generic interface read-back virtual channel identification.

Bit 24 – VPG_ORIENTATION Video Pattern Generator Orientation

Value	Description
0	Vertical color bar orientation.
1	Horizontal color bar orientation.

Bit 20 – VPG_MODE Video Pattern Generator Mode

Value	Description
0	Color bar (horizontal or vertical) pattern is selected.
1	BER pattern (vertical only) is selected.

Bit 16 – VPG_EN Video Pattern Generator Enable

Value	Description
0	Disables the video mode pattern generator.
1	Enables the video mode pattern generator.

Bit 15 – LP_CMD_EN Low Power Command Transmission Enable

Value	Description
0	Disables the command transmission only in Low-Power mode.
1	Enables the command transmission only in Low-Power mode.

Bit 14 – FRAME_BTA_ACK_EN Frame Bus Turn Around Acknowledge Enable

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	Disables the request for an acknowledge response at the end of a frame.
1	Enables the request for an acknowledge response at the end of a frame.

Bit 13 – LP_HFP_EN Low-Power Horizontal Front Porch Enable

Value	Description
0	Disables the return to low-power inside the HFP period when timing allows.
1	Enables the return to low-power inside the HFP period when timing allows.

Bit 12 – LP_HBP_EN Low-Power Horizontal Back Porch Enable

Value	Description
0	Disables the return to low-power inside the HBP period when timing allows.
1	Enables the return to low-power inside the HBP period when timing allows.

Bit 11 – LP_VACT_EN Low-Power Vertical Active Enable

Value	Description
0	Disables the return to low-power inside the VACT period when timing allows.
1	Enables the return to low-power inside the VACT period when timing allows.

Bit 10 – LP_VFP_EN Low-Power Vertical Front Porch Enable

Value	Description
0	Disables the return to low-power inside the VFP period when timing allows.
1	Enables the return to low-power inside the VFP period when timing allows.

Bit 9 – LP_VBP_EN Low-Power Vertical Back Porch Enable

Value	Description
0	Disables the return to low-power inside the VBP period when timing allows.
1	Enables the return to low-power inside the VBP period when timing allows.

Bit 8 – LP_VSA_EN Low-Power Vertical Sync Active Enable

Value	Description
0	Disables the return to low-power inside the VSA period when timing allows.
1	Enables the return to low-power inside the VSA period when timing allows.

Bits 1:0 – VID_MODE_TYPE[1:0] Video Mode Transmission Type
This field indicates the video mode transmission type:

Value	Description
0	Non-burst with sync pulses
1	Non-burst with sync events
2	Burst mode
3	Burst mode

© 2026 Microchip Technology Inc. and its subsidiaries

Reset	0	0	0	0	0	0	0	0

Bits 12:0 – VID_NUM_CHUNKS[12:0] Video Mode Number of Chunks
Configures the number of chunks to be transmitted during a Line period (a chunk is pair made up of a video packet and a null packet). If set to 0 or 1, the video line is still transmitted in a single packet. If set to 1, the packet is part of a chunk, meaning that a null packet follows it (if vid_null_size>0). Otherwise, multiple chunks are used to transmit each video line.

Bit	7	6	5	4	3	2	1	0
							ACK_RQST_EN	TEAR_FX_EN
Access							R/W	R/W
Reset							0	0

Bit 24 – MAX_RD_PKT_SIZE Maximum Read Packet Size
Configures the maximum read packet size command transmission type:

Value	Description
0	High-speed.
1	Low-power.

Bit 19 – DCS_LW_TX DCS Long Write Packet Transmission Type
Configures the DCS long write packet command transmission type:

Value	Description
0	High-speed.
1	Low-power.

Bit 18 – DCS_SR_0P_TX DCS Short Read Packet 0 Transmission Type
Configures the DCS short read packet with zero parameter command transmission type:

Value	Description
0	High-speed.
1	Low-power.

Bit 17 – DCS_SW_1P_TX DCS Short Write Packet 1 Transmission Type
Configures the DCS short write packet with one parameter command transmission type:

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	High-speed.
1	Low-power.

Bit 16 – DCS_SW_0P_TX DCS Short Write Packet 0 Transmission Type
Configures the DCS short write packet with zero parameter command transmission type:

Value	Description
0	High-speed.
1	Low-power.

Bit 14 – GEN_LW_TX Generic Long Write Packet Transmission Type
Configures the Generic long write packet command transmission type:

Value	Description
0	High-speed.
1	Low-power.

Bit 13 – GEN_SR_2P_TX Generic Short Read Packet 2 Transmission Type
Configures the generic short read packet with two parameters command transmission type:

Value	Description
0	High-speed.
1	Low-power.

Bit 12 – GEN_SR_1P_TX Generic Short Read Packet 1 Transmission Type
Configures the generic short read packet with one parameter command transmission type:

Value	Description
0	High-speed.
1	Low-power.

Bit 11 – GEN_SR_0P_TX Generic Short Read Packet 0 Transmission Type
Configures the generic short read packet with zero parameter command transmission type:

Value	Description
0	High-speed.
1	Low-power.

Bit 10 – GEN_SW_2P_TX Generic Short Write Packet 2 Transmission Type
Configures the generic short write packet with two parameters command transmission type:

Value	Description
0	High-speed.
1	Low-power.

Bit 9 – GEN_SW_1P_TX Generic Short Write Packet 1 Transmission Type
Configures the generic short write packet with one parameter command transmission type:

Value	Description
0	High-speed.
1	Low-power.

Bit 8 – GEN_SW_0P_TX Generic Short Write Packet 0 Transmission Type
Configures the generic short write packet with zero parameter command transmission type:

Value	Description
0	High-speed.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	Low-power.

Bit 1 – ACK_RQST_EN Acknowledge Request Enable

Value	Description
0	Disables the acknowledge request after each packet transmission.
1	Enables the acknowledge request after each packet transmission.

Bit 0 – TEAR_FX_EN Tearing Effect Enable

Value	Description
0	Disables the tearing effect acknowledge request.
1	Enables the tearing effect acknowledge request.

Bit	7	6	5	4	3	2	1	0
	GEN_VC[1:0]		GEN_DT[5:0]					
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 23:16 – GEN_WC_MSBYTE[7:0] Generic Interface Word Count Most Significant Byte
Configures the most significant byte of the header packet word count for long packets or data 1 for short packets.

Bits 15:8 – GEN_WC_LSBYTE[7:0] Generic Interface Word Count Least Significant Byte
Configures the least significant byte of the header packet word count for long packets or data 0 for short packets.

Bits 7:6 – GEN_VC[1:0] Generic Interface Virtual Channel
Configures the virtual channel ID of the header packet.

Bits 5:0 – GEN_DT[5:0] Generic Interface Data Type
Configures the packet data type of the header packet.

Reset	0	0	0	0	0	0	0	0

Bits 31:24 – GEN_PLD_B4[7:0] Generic Interface Payload Byte 4
Indicates byte 4 of the packet payload.

Bits 23:16 – GEN_PLD_B3[7:0] Generic Interface Payload Byte 3
Indicates byte 3 of the packet payload.

Bits 15:8 – GEN_PLD_B2[7:0] Generic Interface Payload Byte 2
Indicates byte 2 of the packet payload.

Bits 7:0 – GEN_PLD_B1[7:0] Generic Interface Payload Byte 1
Indicates byte 1 of the packet payload.

Access		R	R	R	R	R	R	R
Reset		0	0	1	0	1	0	1

Bit 19 – GEN_BUFF_PLD_FULL Generic Payload Internal Buffer Full
Indicates the full status of the generic payload internal buffer.

Bit 18 – GEN_BUFF_PLD_EMPTY Generic Payload Internal Buffer Empty
Indicates the empty status of the generic payload internal buffer.

Bit 17 – GEN_BUFF_CMD_FULL Generic Command Internal Buffer Full
Indicates the full status of the generic command internal buffer.

Bit 16 – GEN_BUFF_CMD_EMPTY Generic Command Internal Buffer Empty
Indicates the empty status of the generic command internal buffer.

Bit 6 – GEN_RD_CMD_BUSY Generic Interface Read Command FIFO Busy
Set when a read command is issued and cleared when the entire response is stored in the FIFO for the generic interface.

Bit 5 – GEN_PLD_R_FULL Generic Interface Read Payload FIFO Full
This bit indicates the full status of the generic read payload FIFO.

Bit 4 – GEN_PLD_R_EMPTY Generic Interface Read Payload FIFO Empty
Indicates the empty status of the generic read payload FIFO.

Bit 3 – GEN_PLD_W_FULL Generic Interface Write Payload FIFO Full
Indicates the full status of the generic write payload FIFO.

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 2 – GEN_PLD_W_EMPTY Generic Interface Write Payload FIFO Empty
Indicates the empty status of the generic write payload FIFO.

Bit 1 – GEN_CMD_FULL Generic Interface Command FIFO Full
Indicates the full status of the generic command FIFO.

Bit 0 – GEN_CMD_EMPTY Generic Interface Command FIFO Empty
Indicates the empty status of the generic command FIFO.

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:16 – HSTX_TO_CNT[15:0] High-Speed Transmission Timeout Counter
Configures the timeout counter that triggers a high-speed transmission timeout contention detection (measured in TO_CLK_DIVISION cycles).

Bits 15:0 – LPRX_TO_CNT[15:0] Low-Power Reception Timeout Counter
Configures the timeout counter that triggers a low-power reception timeout contention detection (measured in TO_CLK_DIVISION cycles).

49.7.31. DSI VSS Packet 3D Control Register

Name: DSI_SDF_3D
Offset: 0x90
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
								SEND_3D_CFG
Access								R/W
Reset								0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			RIGHT_FIRST	SECOND_VSYNC	FORMAT_3D[1:0]		MODE_3D[1:0]	
Access			R/W	R/W	R/W	R/W	R/W	R/W
Reset			0	0	0	0	0	0

Bit 16 – SEND_3D_CFG Send 3D Configuration Enable
When set, causes the next VSS packet to include 3D control payload in every VSS packet.

Bit 5 – RIGHT_FIRST Right First
Defines the left/right order:

Value	Description
0	Left eye is sent first, then right eye.
1	Right eye data is sent first, then left eye.

Bit 4 – SECOND_VSYNC Second Vertical Sync Enable
Defines whether there is a second VSYNC pulse between left and right images, when 3D image format is frame-based:

Value	Description
0	No sync pulses between left and right data.
1	Sync pulse (HSYNC, VSYNC, blanking) between left and right data.

Bits 3:2 – FORMAT_3D[1:0] 3D Format
Defines 3D image format:

Value	Description
0	Line (alternating lines of left and right data).
1	Frame (alternating frames of left and right data).
2	Pixel (alternating pixels of left and right data).
3	Reserved

© 2026 Microchip Technology Inc. and its subsidiaries

Bits 1:0 – MODE_3D[1:0] 3D Mode
Defines 3D mode on/off and display orientation:

Value	Description
0	3D mode off (2D mode on).
1	3D mode on, portrait orientation.
2	3D mode on, landscape orientation.
3	Reserved.

							AUTO_CLKLANE_CTRL	PHY_TXREQUESTCLKHS
Access							R/W	R/W
Reset							0	0

Bit 1 – AUTO_CLKLANE_CTRL Automatic Clock Lane Control

Value	Description
0	Disables the automatic mechanism to stop providing the clock in the clock lane when time allows.
1	Enables the automatic mechanism to stop providing clock in the clock lane when time allows.

Bit 0 – PHY_TXREQUESTCLKHS D-PHY High-Speed Transmission Request

Value	Description
0	Disables High-Speed mode transmission request on clock lane.
1	Enables High-Speed mode transmission request on clock lane.

© 2026 Microchip Technology Inc. and its subsidiaries

49.7.33. DSI Clock Lane Switch Mode Timing Configuration Register

Name: DSI_DPHY_TMR_LPCLK_CFG
Offset: 0x98
Reset: 0x00000000

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 25:16 – PHY_HS2LP_TIME[9:0] D-PHY Data High-Speed to Low-Power Time
Configures the maximum time that the D-PHY data lanes take to go from high-speed to low-power transmission measured in lane byte clock cycles.

Bits 9:0 – PHY_LP2HS_TIME[9:0] D-PHY Data Low-Power to High-Speed Time
Configures the maximum time that the D-PHY data lanes take to go from low-power to high-speed transmission measured in lane byte clock cycles.

49.7.35. DSI Reset and PLL Control Register

Name: DSI_DPHY_RSTZ
Offset: 0xA0
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
					DPHY_FORCEPLL	DPHY_ENABLECLK	DPHY_RSTZ	DPHY_SHUTDOWNZ
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit 3 – DPHY_FORCEPLL D-PHY Force PLL Enable

Value	Description
0	Disables the D-PHY PLL when the D-PHY is in ULPS.
1	Enables the D-PHY PLL when the D-PHY is in ULPS.

Bit 2 – DPHY_ENABLECLK D-PHY Enable Clock Lane

Value	Description
0	Disables the D-PHY clock lane module.
1	Enables the D-PHY clock lane module.

Bit 1 – DPHY_RSTZ D-PHY Reset Disable

Value	Description
0	Places the digital section of the D-PHY in the reset state.
1	Allows the digital section of the D-PHY to leave the reset state.

Bit 0 – DPHY_SHUTDOWNZ D-PHY Shutdown Disable

Value	Description
0	Places the complete D-PHY macro in power-down state.
1	Allow the complete D-PHY macro to leave power-down state.

Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
							N_LANES[1:0]	
Access							R/W	R/W
Reset							1	1

Bits 15:8 – PHY_STOP_WAIT_TIME[7:0] D-PHY Stop State Wait Time
Configures the minimum wait period to request a high-speed transmission after the Stop state.

Bits 1:0 – N_LANES[1:0] Number of Active Data Lanes

Value	Description
0	One data lane (lane 0)
1	Two data lanes (lanes 0 and 1)
2	Three data lanes (lanes 0, 1, and 2)
3	Four data lanes (lanes 0, 1, 2, and 3)

Reset					0	0	0	0

Bit 3 – PHY_TXEXITULPSLAN D-PHY Ultra-Low-Power Exit Transmission on Data Lane

Value	Description
0	No effect.
1	ULPS mode exit on clock lane.

Bit 2 – PHY_TXREQULPSLAN D-PHY Ultra-Low-Power Request Transmission on Data Lane

Value	Description
0	No effect.
1	ULPS mode request on data lane.

Bit 1 – PHY_TXEXITULPSCLK D-PHY Ultra-Low-Power Exit Transmission on Clock Lane

Value	Description
0	No effect.
1	ULPS mode exit on clock lane.

Bit 0 – PHY_TXREQULPSCLK D-PHY Ultra-Low-Power Request Transmission on Clock Lane

Value	Description
0	No effect.
1	ULPS mode request on clock lane.

Reset	–	–	–	–	–	–	–	–

Bit 12 – PHY_ULPSACTIVENOT3LANE D-PHY Ultra-Low-Power State Active on Data Lane 3 Status

Value	Description
0	Data lane 3 is in Ultra-Low-Power (ULP) state.
1	Data lane 3 is not in Ultra-Low-Power (ULP) state.

Bit 11 – PHY_STOPSTATE3LANE D-PHY Stop State on Data Lane 3 Status

Value	Description
0	Data lane 3 module is not in Stop state.
1	Data lane 3 module is in Stop state.

Bit 10 – PHY_ULPSACTIVENOT2LANE D-PHY Ultra-Low-Power State Active on Data Lane 2 Status

Value	Description
0	Data lane 2 is in Ultra-Low-Power (ULP) state.
1	Data lane 2 is not in Ultra-Low-Power (ULP) state.

Bit 9 – PHY_STOPSTATE2LANE D-PHY Stop State on Data Lane 2 Status

Value	Description
0	Data lane 2 module is not in Stop state.
1	Data lane 2 module is in Stop state.

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 8 – PHY_ULPSACTIVENOT1LANE D-PHY Ultra-Low-Power State Active on Data Lane 1 Status

Value	Description
0	Data lane 1 is in Ultra-Low-Power (ULP) state.
1	Data lane 1 is not in Ultra-Low-Power (ULP) state.

Bit 7 – PHY_STOPSTATE1LANE D-PHY Stop State on Data Lane 1 Statu

Value	Description
0	Data lane 1 module is not in Stop state.
1	Data lane 1 module is in Stop state.

Bit 6 – PHY_RXULPSESC0LANE Ultra-Low-Power State Escape Code Reception

Value	Description
0	Data lane 0 is not in Ultra Low-Power state after reception of the Ultra Low-Power state Escape code.
1	Data lane 0 is in Ultra Low-Power state after reception of the Ultra Low-Power state Escape code.

Bit 5 – PHY_ULPSACTIVENOT0LANE D-PHY Ultra-Low-Power State Active on Data Lane 0 Status

Value	Description
0	Data lane 0 is in Ultra-Low-Power (ULP) state.
1	Data lane 0 is not in Ultra-Low-Power (ULP) state.

Bit 4 – PHY_STOPSTATE0LANE D-PHY Stop State on Data Lane 0 Status

Value	Description
0	Data lane 0 module is not in Stop state.
1	Data lane 0 module is in Stop state.

Bit 3 – PHY_ULPSACTIVENOTCLK D-PHY Ultra-Low-Power State Active on Clock Lane Status

Value	Description
0	The clock lane is in Ultra-Low-Power (ULP) state.
1	The clock lane is not in the Ultra-Low-Power state.

Bit 2 – PHY_STOPSTATECLKLANE D-PHY Stop State Clock Lane Status

Value	Description
0	The clock lane module is not in Stop state.
1	The clock lane module is in Stop state.

Bit 1 – PHY_DIRECTION D-PHY Direction Status
Used to indicate the current direction of the lane interconnect.

Value	Description
0	The lane interconnect is in Transmit mode.
1	The lane interconnect is in Receive mode.

Bit 0 – PHY_LOCK D-PHY Lock Status
When set, indicates that the PLL acquired the lock with the reference clock.

Bit 20 – DPHY_ERRORS_4 D-PHY Errors 4
Indicates LP1 contention error ErrContentionLP1 from Lane 0.

Bit 19 – DPHY_ERRORS_3 D-PHY Errors 3
Indicates LP0 contention error ErrContentionLP0 from Lane 0.

Bit 18 – DPHY_ERRORS_2 D-PHY Errors 2
Indicates control error ErrControl from Lane 0.

Bit 17 – DPHY_ERRORS_1 D-PHY Errors 1
Indicates ErrSyncEsc low-power data transmission synchronization error from Lane 0.

Bit 16 – DPHY_ERRORS_0 D-PHY Errors 0
This bit indicates ErrEsc escape entry error from Lane 0.

Bit 15 – ACK_WITH_ERR_15 Acknowledge With Error 15
Retrieves the DSI protocol violation from the Acknowledge error report.

Bit 14 – ACK_WITH_ERR_14 Acknowledge With Error 14
Retrieves the reserved (specific to device) from the Acknowledge error report.

Bit 13 – ACK_WITH_ERR_13 Acknowledge With Error 13
Retrieves the invalid transmission length from the Acknowledge error report.

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 12 – ACK_WITH_ERR_12 Acknowledge With Error 12
Retrieves the DSI VC ID Invalid from the Acknowledge error report.

Bit 11 – ACK_WITH_ERR_11 Acknowledge With Error 11
Retrieves the not recognized DSI data type from the Acknowledge error report.

Bit 10 – ACK_WITH_ERR_10 Acknowledge With Error 10
Retrieves the checksum error (long packet only) from the Acknowledge error report.

Bit 9 – ACK_WITH_ERR_9 Acknowledge With Error 9
Retrieves the ECC error, multi-bit (detected, not corrected) from the Acknowledge error report.

Bit 8 – ACK_WITH_ERR_8 Acknowledge With Error 8
Retrieves the ECC error, single-bit (detected and corrected) from the Acknowledge error report.

Bit 7 – ACK_WITH_ERR_7 Acknowledge With Error 7
Retrieves the reserved (specific to device) from the acknowledge error report.

Bit 6 – ACK_WITH_ERR_6 Acknowledge With Error 6
Retrieves the False Control error from the Acknowledge error report.

Bit 5 – ACK_WITH_ERR_5 Acknowledge With Error 5
Retrieves the Peripheral Timeout error from the Acknowledge error report.

Bit 4 – ACK_WITH_ERR_4 Acknowledge With Error 4
Retrieves the LP Transmit Sync error from the Acknowledge error report.

Bit 3 – ACK_WITH_ERR_3 Acknowledge With Error 3
Retrieves the Escape Mode Entry Command error from the Acknowledge error report.

Bit 2 – ACK_WITH_ERR_2 Acknowledge With Error 2
Retrieves the EoT Sync error from the Acknowledge error report.

Bit 1 – ACK_WITH_ERR_1 Acknowledge With Error 1
Retrieves the SoT Sync error from the Acknowledge error report.

Bit 0 – ACK_WITH_ERR_0 Acknowledge With Error 0
Retrieves the SoT error from the Acknowledge error report.

Reset	0	0	0	0	0	0	0	0

Bit 19 – DPI_BUFF_PLD_UNDER Input Video Interface Payload Buffer Underflow Status
Indicates that an underflow has occurred when reading the payload to build a DSI packet for Video mode.

Bit 12 – GEN_PLD_RECEV_ERR Generic Interface Payload Receive Error Status
Indicates that during a generic interface packet read back, the payload FIFO becomes full and the received data is corrupted.

Bit 11 – GEN_PLD_RD_ERR Generic Interface DCS Payload Read Error Status
Indicates that during a DCS read data, the payload FIFO becomes empty and the data sent to the interface is corrupted.

Bit 10 – GEN_PLD_SEND_ERR Generic Interface Payload Send Error Status
Indicates that during a generic interface packet build, the payload FIFO becomes empty and corrupt data is sent.

Bit 9 – GEN_PLD_WR_ERR Generic Interface Payload Write Error Status
Indicates that the system tried to write a payload data through the Generic interface and the FIFO is full. Therefore, the payload is not written.

Bit 8 – GEN_CMD_WR_ERR Generic Interface Command Write Error Status
Indicates that the system tried to write a command through the Generic interface and the FIFO is full. Therefore, the command is not written.

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 7 – DPI_PLD_WR_ERR Input Video Payload Write Error Status
Indicates that during a DPI pixel line storage, the payload FIFO becomes full and the data stored is corrupted.

Bit 6 – EOTP_ERR End Of Transmission Packet Error Status
Indicates that the EoTp packet has not been received at the end of the incoming peripheral transmission.

Bit 5 – PKT_SIZE_ERR Packet Size Error Status
Indicates that the packet size error has been detected during the packet reception.

Bit 4 – CRC_ERR CRC Error Status
Indicates that the CRC error has been detected in the received packet payload.

Bit 3 – ECC_MULTI_ERR ECC Multiple Error Status
Indicates that the ECC multiple error has been detected in a received packet.

Bit 2 – ECC_SINGLE_ERR ECC Single Error Status
Indicates that the ECC single error has been detected and corrected in a received packet.

Bit 1 – TO_LP_RX Low-Power Reception Timeout Status
Indicates that the low-power reception timeout counter reached the end and contention has been detected.

Bit 0 – TO_HS_TX High-Speed Transmission Timeout Status
Indicates that the high-speed transmission timeout counter reached the end and contention has been detected.

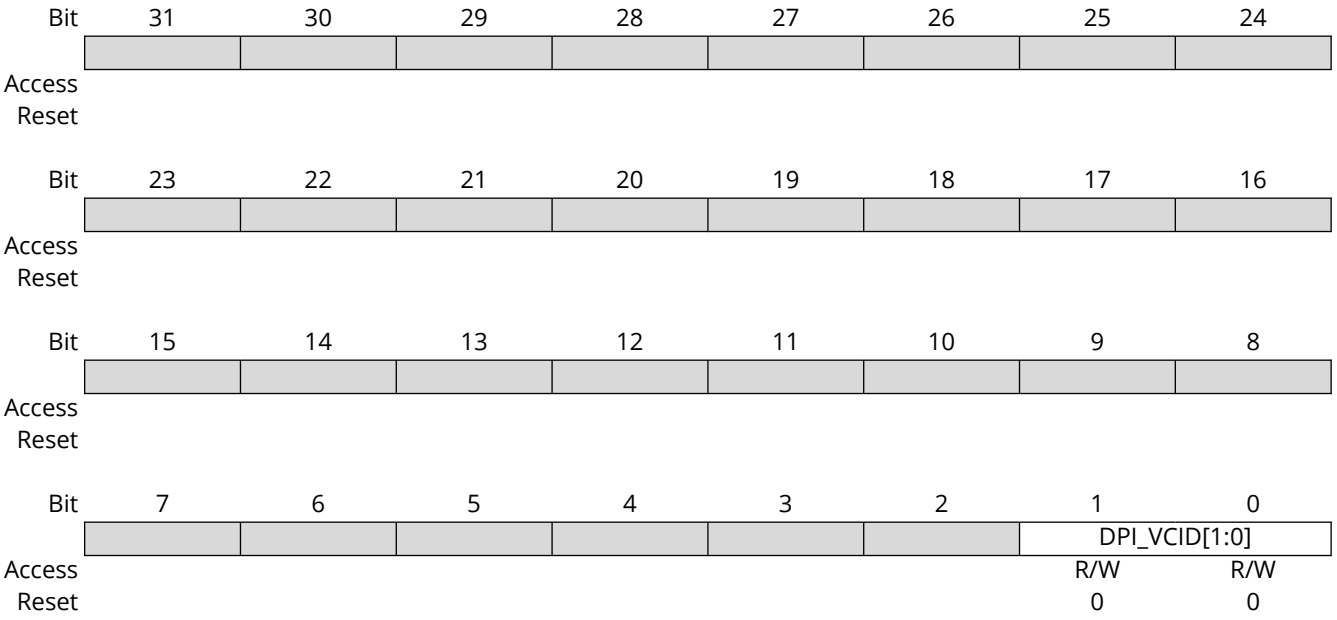
								VID_SHADOW_EN
Access								R/W
Reset								0

Bit 8 – VID_SHADOW_REQ Video Interface Shadow Request

Value	Description
0	No effect.
1	Requests that the input video interface registers from regbank are copied to the auxiliary registers. When the request is completed, this bit is automatically cleared.



Bit 0 – VID_SHADOW_EN Video Interface Shadow Registers Enable

Value	Description
0	No effect.
1	Input video bus receives the active configuration from the auxiliary registers. When the feature is set at the same time as VID_SHADOW_REQ, the auxiliary registers are automatically updated.

Reset	0	0	0	0	0	0	0	0

Bits 23:16 – OUTVACT_LPCMD_TIME[7:0] Output Vertical Active Low-Power Command Time
Used for the transmission of commands in Low-Power mode. It specifies the size, in bytes, of the largest packet that can fit in a line during the VSA, VBP, and VFP regions.

Bits 7:0 – INVACT_LPCMD_TIME[7:0] Input Vertical Active Low-Power Command Time
Used for the transmission of commands in Low-Power mode. It specifies the size, in bytes, of the largest packet that can fit in a line during the VACT region.

Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit 9 – LP_CMD_EN Low-Power Command Enable

Value	Description
0	Disables the command transmission only in Low-Power mode.
1	Enables the command transmission only in Low-Power mode.

Bit 8 – FRAME_BTA_ACK_EN Frame Bus Turn Around Acknowledge Enable

Value	Description
0	Disables the request for an acknowledge response at the end of a frame.
1	Enables the request for an acknowledge response at the end of a frame.

Bit 7 – LP_HFP_EN Low-Power Horizontal Front Proch Enable

Value	Description
0	Disables return to low-power inside the HFP period when timing allows.
1	Enables the return to low-power inside the HFP period when timing allows.

Bit 6 – LP_HBP_EN Low-Power Horizontal Back Proch Enable

Value	Description
0	Disables the return to low-power inside the HBP period when timing allows.
1	Enables the return to low-power inside the HBP period when timing allows.

Bit 5 – LP_VACT_EN Low-Power Vertical Active Enable

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	Disables the return to low-power inside the VACT period when timing allows.
1	Enables the return to low-power inside the VACT period when timing allows.

Bit 4 – LP_VFP_EN Low-Power Vertical Front Porch Enable

Value	Description
0	Disables the return to low-power inside the VFP period when timing allows.
1	Enables the return to low-power inside the VFP period when timing allows.

Bit 3 – LP_VBP_EN Low-Power Vertical Back Porch Enable

Value	Description
0	Disables the return to low-power inside the VBP period when timing allows.
1	Enables the return to low-power inside the VBP period when timing allows.

Bit 2 – LP_VSA_EN Low-Power Vertical Sync Active Enable

Value	Description
0	Disables the return to low-power inside the VSA period when timing allows.
1	Enables the return to low-power inside the VSA period when timing allows.

Bits 1:0 – VID_MODE_TYPE[1:0] Video Mode Type
Specifies the video mode transmission type.

Value	Description
0	Non-burst with sync pulses
1	Non-burst with sync events
2	Burst mode
3	Burst mode

© 2026 Microchip Technology Inc. and its subsidiaries

49.7.55. DSI Video Mode Packet Size Active Value Register

Name: DSI_VID_PKT_SIZE_ACT

	VID_NUM_CHUNKS[7:0]							
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 12:0 – VID_NUM_CHUNKS[12:0] Video Mode Number of Chunks
Specifies the number of chunks to be transmitted during a line period (a chunk is pair made of a video packet and a null packet). If set to 0 or 1, the video line is still transmitted in a single packet. If set to 1, that packet is part of a chunk, meaning that a null packet follows it (if vid_null_size>0). Otherwise, multiple chunks are used to transmit each video line.

Bit 17 – DPI_BUFF_PLD_FULL Input Video Interface Write Payload FIFO Full
Indicates the full status of the payload internal buffer for Video mode.

Bit 16 – DPI_BUFF_PLD_EMPTY Input Video Interface Write Payload FIFO Empty
Indicates the empty status of the payload internal buffer for Video mode.

Bit 3 – DPI_PLD_W_FULL Input Video Interface Write Payload FIFO Full
Indicates the full status of the write payload FIFO for Video mode.

Bit 2 – DPI_PLD_W_EMPTY Input Video Interface Write Payload FIFO Empty
Indicates the empty status of the write payload FIFO for Video mode.

Bit 1 – DPI_CMD_W_FULL Input Video Interface Command FIFO Full
Indicates the full status of the write command FIFO for Video mode.

Bit 0 – DPI_CMD_W_EMPTY Input Video Interface Command FIFO Empty
Indicates the empty status of the write command FIFO for Video mode.

49.7.66. DSI VSS Packet 3D Active Value Register

Name: DSI_SDF_3D_ACT
Offset: 0x190
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
								SEND_3D_CFG
Access								R
Reset								0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			RIGHT_FIRST	SECOND_VSYNC	FORMAT_3D[1:0]		MODE_3D[1:0]	
Access			R	R	R	R	R	R
Reset			0	0	0	0	0	0

Bit 16 – SEND_3D_CFG Send 3D Configuration Enable
When set, causes the next VSS packet to include 3D control payload in every VSS packet.

Bit 5 – RIGHT_FIRST Right First
Specifies the left/right order:

Value	Description
0	Left eye is sent first, then right eye.
1	Right eye data is sent first, then left eye.

Bit 4 – SECOND_VSYNC Second Vertical Sync Enable
Specifies whether there is a second VSYNC pulse between Left and Right Images, when 3D Image Format is Frame-based:

Value	Description
0	No sync pulses between left and right data.
1	Sync pulse (HSYNC, VSYNC, blanking) between left and right data.

Bits 3:2 – FORMAT_3D[1:0] 3D Format
Specifies 3D image format:

Value	Description
0	Line (alternating lines of left and right data).
1	Frame (alternating frames of left and right data).
2	Pixel (alternating pixels of left and right data).
3	Reserved

© 2026 Microchip Technology Inc. and its subsidiaries

Bits 1:0 – MODE_3D[1:0] 3D Mode
Specifies 3D Mode on/off and display orientation:

Value	Description
0	3D Mode off (2D Mode on).
1	3D Mode on, portrait orientation.
2	3D Mode on, landscape orientation.
3	Reserved.

50. Camera Serial Interface (CSI)

50.1. Description

The Camera Serial Interface (CSI) receives data from a CSI-2-compliant camera sensor. A D-PHY configured as a client (RX) acts as the physical layer.

The CSI implements the MIPI CSI-2 protocol specification. The CSI-2 link protocol specification is a part of communication protocols defined by MIPI Alliance standards intended for mobile system chip-to-chip communications. The CSI-2 specification is for the image application processor communication in cameras.

50.2. Embedded Characteristics

The CSI is compliant with the following standards:

- MIPI Alliance Specification for Camera Serial Interface 2 (CSI-2), Version 1.2
- MIPI Alliance Specification for D-PHY, Version 1.2

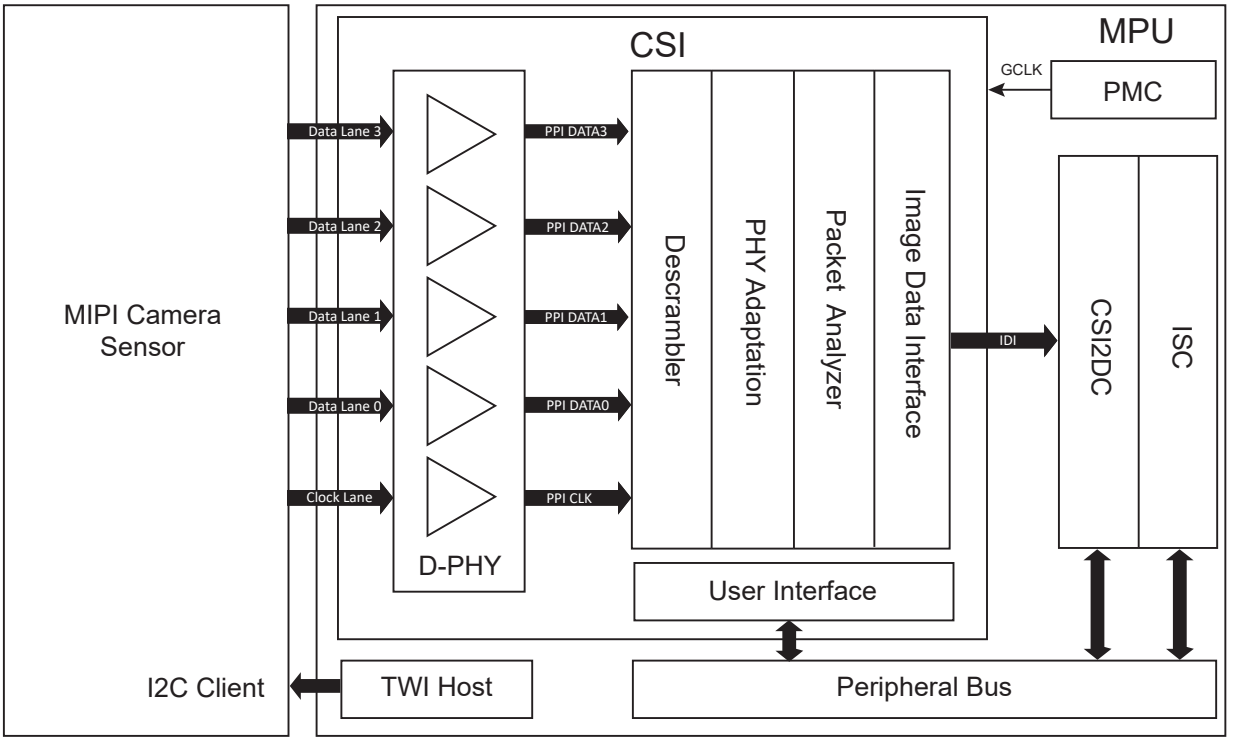
D-PHY Characteristics:

- Four-lane Receive MIPI D-PHY Compliant with Revision 1.1 Specification
- Lane Operation Ranging from 80 Mbps to 1 Gbps in Forward Direction
- Aggregate Throughput up to 4 Gbps with Four Data Lanes
- Low-Power Escape Modes and Ultra-Low-Power (ULP) State

CSI-2 Host Characteristics:

- Dynamically Configurable Multi-Lane Merging
- Long and Short Packet Decoding
- Timing Accurate Signaling of Frame and Line Synchronization Packets
- Frame Formats:
  - General frame or digital interlaced video with or without accurate sync timing
  - Data type (packet or frame level) and virtual channel interleaving
- All Primary and Secondary Data Formats.
  - YUV, RGB, RAW (for details, refer to the section "Image Sensor Interface (ISC)")
  - Generic 8-bit long packet data types
  - User-defined byte-based data
- Error Detection and Correction
  - PHY level
  - Packet level
  - Line level
  - Frame level
- EMI Mitigation

50.3. I/O Lines Description



Signal Name	Type	Function
MIPI_DP0	Input	Positive D-PHY differential data line receiver, Lane 0
MIPI_DN0	Input	Negative D-PHY differential data line receiver, Lane 0
MIPI_DP1	Input	Positive D-PHY differential data line receiver, Lane 1

© 2026 Microchip Technology Inc. and its subsidiaries

I/O Lines Description (continued)		
Signal Name	**Type**	**Function**
MIPI_DN1	Input	Negative D-PHY differential data line receiver, Lane 1
MIPI_DP2	Input	Positive D-PHY differential data line receiver, Lane 2
MIPI_DN2	Input	Negative D-PHY differential data line receiver, Lane 2
MIPI_DP3	Input	Positive D-PHY differential data line receiver, Lane 3
MIPI_DN3	Input	Negative D-PHY differential data line receiver, Lane 3
MIPI_CLKP	Input	Positive D-PHY differential clock line receiver
MIPI_CLKN	Input	Negative D-PHY differential clock line receiver
MIPI_REXT	Input	D-PHY external resistor connection

50.4. Block Diagram

Figure 50.1. CSI Block Diagram

50.5. Product Dependencies

50.5.1. I/O Lines

The D-PHY can be used either by DSI or CSI hosts. The programmer must first configure a dedicated Special Function Register, SFR_ISS_CFG, to connect D-PHY to CSI (refer to the section "Special Function Register (SFR)").

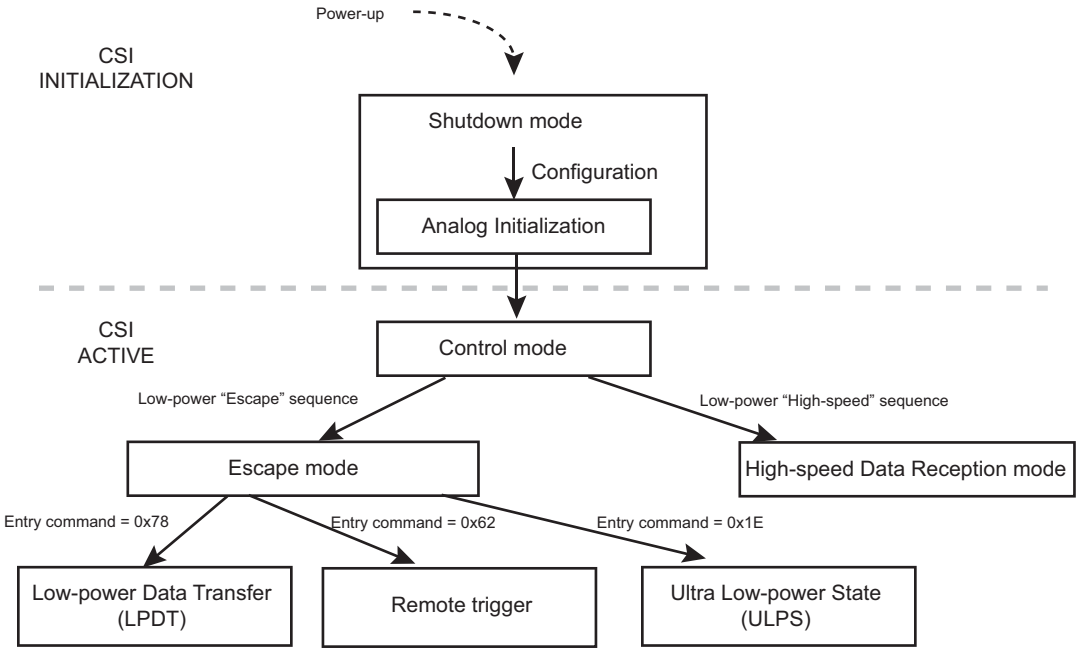
50.5.2. Power Management

The CSI is not continuously clocked. Before using it, the programmer must first enable the CSI and the MIPI D-PHY peripheral clocks in the Power Management Controller (PMC).

50.5.3. Interrupt Sources

The CSI interrupt line is connected to one of the internal sources of the interrupt controller. Using the CSI interrupt requires prior programming of the interrupt controller.

© 2026 Microchip Technology Inc. and its subsidiaries



50.6. Functional Description

The CSI interfaces the Image Sensor Controller (ISC) and a MIPI CSI-2 compliant Camera Sensor.

50.6.1. D-PHY Operating Modes

The following figure illustrates the D-PHY initialization from Shutdown to Active modes.

Figure 50.2. D-PHY Initialization from Shutdown to Active Modes

50.6.1.1. Shutdown Mode

Shutdown mode is the operating mode with the lowest power consumption. All analog blocks are disabled, and digital logic is reset. To enter this mode, write to '0' the bits DPHY_RSTZ in the Reset register (CSI_DPHY_RSTZ) and PHY_SHUTDOWNZ in the Shutdown register (CSI_PHY_SHUTDOWNZ). The bit PHY_TESTCLR in the Analog Configuration Control register (CSI_PHY_TEST_CTRL0) is asserted by default.

In Shutdown mode, the differential lines of MIPI_DNx/Px and MIPI_CLKN/P are high impedance (Hi-Z).

By default, the D-PHY is configured to work only on the lower operating range of 80-110 Mbps. If higher bit rate operation is required, the register hsfreqrange (HS RX Control of Lane 0) must be set with the proper code. If the D-PHY is expected to change the bit rate after initialization, hsfreqrange must be updated while in Control mode.

When CSI_DPHY_RSTZ.DPHY_RSTZ and CSI_PHY_SHUTDOWNZ.PHY_SHUTDOWNZ are set to '1', the D-PHY exits Shutdown mode and starts an initialization procedure.

50.6.1.2. Analog Initialization

The D-PHY comprises 4 data lanes, but some applications may require fewer. The number of lanes is configured in the Lane Configuration register (CSI_N_LANES) and must be done only when the D-PHY is in Shutdown mode.

Before starting normal operation, a D-PHY bit rate code must be configured as shown in the following table. Follow the steps listed below for configuration:

1. Ensure that the D-PHY is in Shutdown mode. See Shutdown Mode.
2. Reset the analog configuration by generating a high pulse on CSI_PHY_TEST_CTRL0. PHY_TESTCLR.

© 2026 Microchip Technology Inc. and its subsidiaries

3. Write a '1' to CSI_PHY_TEST_CTRL0.PHY_TESTCLK.
4. Write 0x44 to CSI_PHY_TEST_CTRL1.PHY_TESTDIN and write a '1' to CSI_PHY_TEST_CTRL1.PHY_TESTEN.
5. Write a '0' to CSI_PHY_TEST_CTRL0.PHY_TESTCLK to create a falling edge on PHY_TESTCLK.
6. Write a '0' to CSI_PHY_TEST_CTRL1.PHY_TESTEN and write the configuration value from the following table to CSI_PHY_TEST_CTRL1.PHY_TESTDIN.
7. Write a high pulse to CSI_PHY_TEST_CTRL0.PHY_TESTCLK by writing '1' immediately followed by '0'.

Table 50.1. Bit Rate Ranges

Range (Mbps)	High-Speed Bit Rate Code
80-89	000000
90-99	010000
100-109	100000
110-129	000001
130-139	010001
140-149	100001
150-169	000010
170-179	010010
180-199	100010
200-219	000011
220-239	010011
240-249	100011
250-269	000100
270-299	010100
300-329	000101
330-359	010101
360-399	100101
400-449	000110
450-499	010110
500-549	000111
550-599	010111
600-649	001000
650-699	011000
700-749	001001
750-799	011001
800-849	101001
850-899	111001
900-949	001010
950-1000	011010

The initialization period is a protocol-dependent parameter with a minimum of 100 µs defined by the specification. The D-PHY starts decoding the low-power commands after the analog initialization.

50.6.1.3.Active Modes

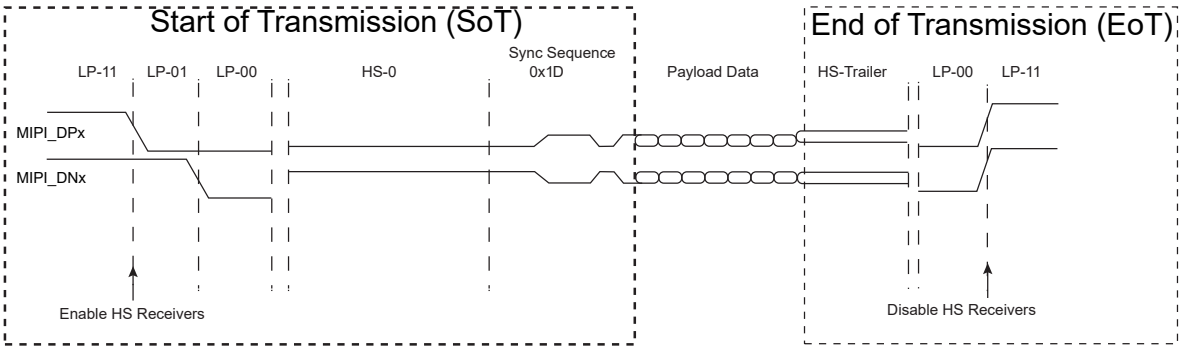
50.6.1.3.1.Control Mode

Control mode is the default operating mode. After initialization is completed (analog calibrations), the D-PHY remains in this default mode until a request is placed. The request is placed directly

© 2026 Microchip Technology Inc. and its subsidiaries

through the sequence of low-power signals in the lanes. The receiver remains in Control mode while receiving Low-power (LP) Stop state (LP-11) in the lines (see the following figure).

Following a request, a lane can exit Control mode for High-speed Data Transfer mode or Escape mode.



50.6.1.3.2.High-Speed Data Reception Mode

High-speed data reception occurs in bursts. Only during these bursts is the lane in High-Speed mode. A high-speed burst must start from and return to a Stop state (Control mode).

Each data lane can receive a high-speed transmission independently of the state of the remaining data lanes.

A burst contains the low-power initialization sequence, the high-speed data payload, and the end-of-transmission sequence.

Figure 50.3. HS Data Reception Sequence

The D-PHY receiver enters High-Speed mode following the sequence of low-power states in the lines LP-11, LP-01, and LP-00. This sequence is seen as a High-Speed mode request, and toggles the enabling of the high-speed receivers. Synchronization is then achieved through the identification of the leader sequence in the received differential high-speed data. Once the synchronization is achieved, the D-PHY outputs the received bytes through the protocol layer, until a Stop state (LP-11) is detected in the lane.

50.6.1.3.3.Escape Mode

Escape mode is a special mode of operation that uses the data lanes to communicate asynchronously using the low-power states at low speed. A data lane enters Escape mode through an Escape mode entry procedure (LP-11, LP-10, LP-00, LP-01, LP-00). If an LP-11 is detected before reaching LP-00 state, the entry is aborted and the receiver returns to the Stop state. Once the sequence is correctly completed, the transmitter sends an 8-bit command to indicate a requested action. The table below shows the actions supported by Escape mode. If the entry command is invalid, the PHY_ERRESC_x error flag goes high, and the receiver waits until the transmitter returns to the Stop state.

Table 50.2. Possible Escape Mode Sequences for Data Lanes

Escape Mode Action	Entry Command Pattern (First Bit to Last Bit to be Transmitted)	Command Type
Ultra-Low-Power State	0x1E	mode
Reset Trigger	0x62	trigger
Low-Power Data Transmission	0x87	mode

© 2026 Microchip Technology Inc. and its subsidiaries

Low-Power Data Transmission (LPDT)

In LPDT mode, the data can be received on the lines at low speed in Low-Power mode. High-speed receivers are off and low-power receivers are on. During LPDT, the protocol can pause by maintaining a Space state on the lines.

Remote Trigger

In Remote Trigger mode, the protocol can send a flag to the receiving side at the request of the transmitting side.

In Escape mode, the RXCLKESC can stop at anytime in either Low or High state.

Ultra-Low-Power State (ULPS)

Ultra-Low-Power State (ULPS) mode has the lowest power consumption, excluding the Shutdown mode.

For data lanes, this mode is entered by sending an ULPS entry command, after the Escape mode entry command. During this mode, the lines are in the Space state (LP-00). Although the clock lane does not support regular Escape mode, the clock lane supports ULPS.

50.6.2. Supported Resolutions and Frame Rates

The table below presents some predefined and supported camera settings, assuming the following:

- D-PHY: clock lane frequency is in the range of 250 MHz to 500 MHz, which results in a bandwidth of 500 Mbps to 1 Gbps for each data lane.
- No significant control/reserved traffic is present on the link when pixel data is being transmitted.

Table 50.3. Examples of Supported Resolutions and Frame Rates

	Number of Pixels with Overhead	Refresh Rate (Hz)	Color Depth (bpp)	CSI-2 Bandwidth (Mbits)	D-PHY at 500 Mbps Number of Lanes	D-PHY at 1 Gbps Number of Lanes
Camera Formats						
2 Mpixels	2560000	15	24	922	2	1
3 Mpixels	3840000	15	24	1382	3	2
5 Mpixels	5500000	15	24	1980	4	2
Video Formats						
1280x720 pixels (720p)	921600	30	24	664	2	1
1280x720 pixels (720p)	921600	60	24	1327	3	2

Note: The CSI does not perform data decompression. For example, if a camera transmits the compressed data according to the Annex E of the CSI-2 Specification (data compression for raw data types), the CSI decodes the data as normal non-compressed raw data. The decompression is performed by the CSI2DC block.

50.6.3. Descrambler

Data scrambling is used to mitigate the effects of EMI and RF self-interference. The data that is being transmitted is scrambled with a Pseudo-Random Binary Sequence.

The pseudo-random binary sequence can be different on each lane by configuring the Lane 0/1/2/3 Scrambling Seed registers (CSI_SCRAMBLING_SEED1/2/3/4). The default seed values after reset of the controller are given in the table below.

Lane	Initial Seed Value
0	0x1008

© 2026 Microchip Technology Inc. and its subsidiaries

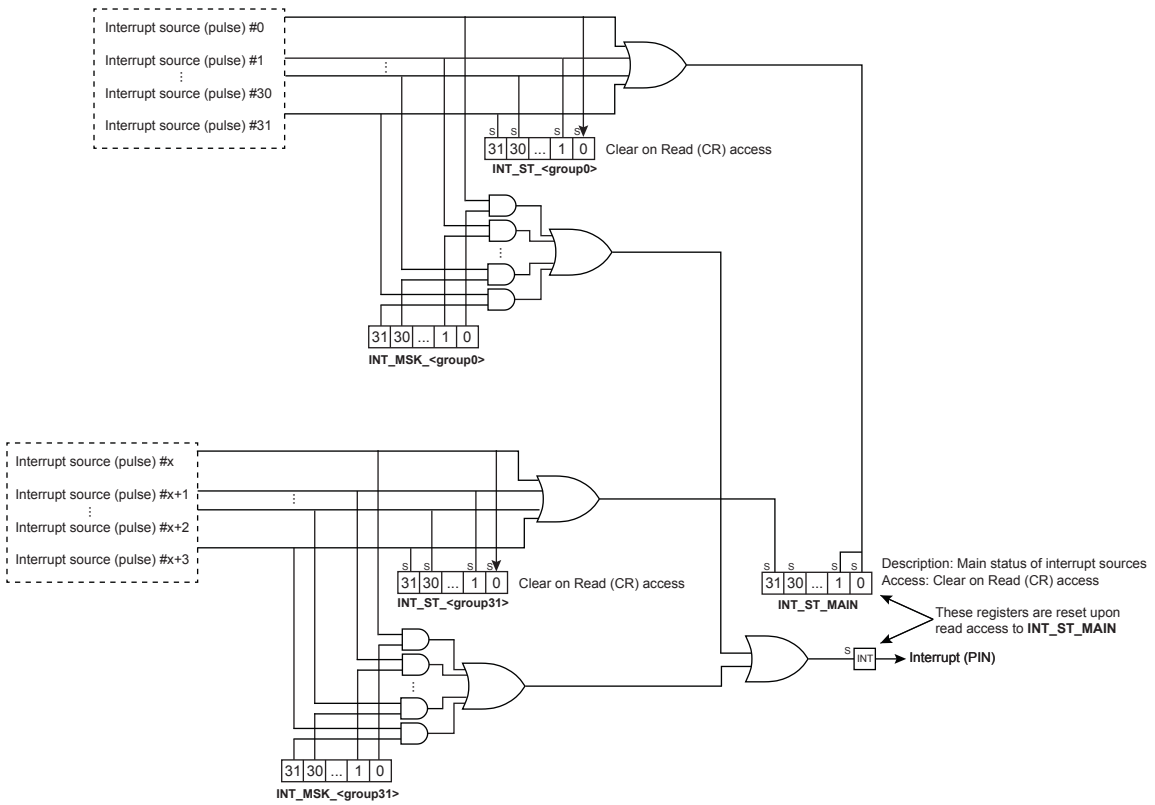
Descrambler (continued)	
Lane	**Initial Seed Value**
1	0x1188
2	0x1248
3	0x1428

The descrambler is enabled using the bit SCRAMBLE_ENABLE in the Descrambler Configuration register (CSI_SCRAMBLING).

Selecting the seed used by the descrambler block is done in the registers CSI_SCRAMBLING_SEED1/2/3/4.

50.6.4. Interrupts

The Interrupt Status registers report error conditions.



The triggering of the CSI interrupt line can be masked by programming the Interrupt Mask registers. By default, all errors are masked. When any bit of these registers is set to 1, it enables the interrupt for a specific error.

The Interrupt Status registers are cleared on read.

The Interrupt Force registers (CSI_INT_FORCE_<group>) are used for test purposes, and trigger interrupt events individually. Setting any bit of these registers to 1 triggers the corresponding interrupt.

The figure below shows the main parts of the interrupt mechanism.

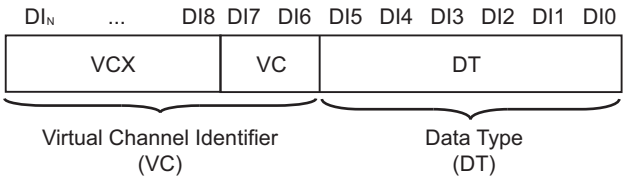
Figure 50.4. Interrupt Mechanism

© 2026 Microchip Technology Inc. and its subsidiaries

50.6.5. Error Detection

The CSI analyzes the received packets and determines if there are protocol errors. The following errors are monitored:

- Frame errors, such as incorrect frame sequence, reception of a CRC error in the most recent frame, and the mismatch between Frame Start and Frame End
- Line errors, such as incorrect line sequence and mismatch between Line Start and Line End
- Packet errors, such as payload CRC and ECC (D-PHY)
- D-PHY errors, such as synchronization pattern mismatch



50.6.5.1. Data ID Monitors

According to the CSI-2 Specification, each CSI-2 line contains information regarding Data Type (DT) and Virtual Channel (VC) identification. Yet, each CSI-2 frame is identified uniquely by its virtual channel. In fact, a frame can contain different lines using different data types.

This fact imposes some restriction on how errors are monitored for CSI-2 lines. To have a mechanism to identify these errors, it is required to have the knowledge of the DT and VC pairs that are active on the CSI-2 link. These errors are monitored in the following registers:

- CSI_DATA_IDS_1
- CSI_DATA_IDS_VC_1
- CSI_DATA_IDS_2
- CSI_DATA_IDS_VC_2

Figure 50.5. Definition of Data ID

The CSI_DATA_IDS and CSI_DATA_IDS_VC register s, if selected during core configuration, must be programmed during controller initialization only.

For further details, detect the protocol layer errors and report the errors as follows:

- Analyze the data type field of the headers of short and long packets, and raise an error whenever an unrecognized or unimplemented one is found. This corresponds to ERR_ID and is reported for each virtual channel, independently (ERR_ID_VCx fields in CSI_INT_ST_DATA_ID).
- Take note of the occurrence of payload CRC error detections in any of the packets that are received between a Frame Start and its corresponding Frame End. When the Frame End is received, ERR_FRAME_DATA error is raised for the virtual channel where the frame has been received, if at least one payload CRC error has been detected in some packet of that frame (ERR_FRAME_DATA_VCx fields in CSI_INT_ST_CRC_FRAME_FATAL).
- Analyze the headers of short packets, aiming to match Frame Start with Frame End and Line Start with Line End packets by the corresponding Frame Number or Line Number.
  - If there are two consecutive Frame Start packets or two consecutive Frame End ones, or even if the Frame Number of a Frame End packet is not the same as for the last received Frame Start (all verified in the same virtual channel), an ERR_F_BNDRY_MATCH error is raised (ERR_F_BNDRY_MATCH_VCx fields in CSI_INT_ST_BNDRY_FRAME_FATAL).
  - If the frame number in a Frame Start packet is not incremented by 1 relatively to the previous one, for some virtual channel, an ERR_F_SEQ error is raised. The exception is that if the Frame Number is 0, frame numbering is inactive; if it is 1, the frame numbers

© 2026 Microchip Technology Inc. and its subsidiaries

restart. Therefore, the error is not raised in these exceptions (ERR_F_SEQ_VCx fields in CSI_INT_ST_SEQ_FRAME_FATAL).

- If there are two consecutive Line Start packets or two consecutive Line End ones, or even if the line number of a Line End packet is not the same as for the last received Line Start (all verified in the same virtual channel), an ERR_L_BNDRY_MATCH error is raised for each data ID of long packets that have been received in between and that match the data IDs that are programmed in the register bank (ERR_L_BNDRY_MATCH_DIx fields in CSI_INT_ST_LINE, where DIx corresponds to the data ID programmed in CSI_DATA_IDS_1, CSI_DATA_IDS_2, CSI_DATA_IDS_VC1, CSI_DATA_IDS_VC_2).
- The line number of each Line Start packet is saved, according to its virtual channel. Later, when a long packet is received for the same virtual channel, if its data ID is programmed in the register bank and if that line number is out of the expected sequence for that data ID, an ERR_L_SEQ error is raised for that data ID. Prior to raising any ERR_L_SEQ error, the increment between successive lines for a given data ID has to be determined. For that, at least two consecutive lines of a given data ID must be received without errors after each frame starts, so that the difference between those two line numbers can be used to determine the increment of the line numbers to expect for that data ID (ERR_L_SEQ_DIx fields in CSI_INT_ST_LINE, where DIx corresponds to the data ID programmed in CSI_DATA_IDS_1, CSI_DATA_IDS_2, CSI_DATA_IDS_VC1, CSI_DATA_IDS_VC_2).

All the errors described previously can trigger one of the two interrupt pins. Any of these errors can be independently masked to inhibit the generation of interrupts.

50.7.1. CSI Lane Configuration Register

Name: CSI_N_LANES
Offset: 0x4
Reset: 0x00000003
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							N_LANES[1:0]	
Access							R/W	R/W
Reset							1	1

Bits 1:0 – N_LANES[1:0] Number of active data lanes
The update can be performed only when the D-PHY is in Stop state.

Value	Name	Description
0	1_LANE	One data lane
1	2_LANES	Two data lanes
2	3_LANES	Three data lanes
3	4_LANES	Four data lanes

50.7.2. CSI Reset Control Register

Name: CSI_CSI2_RESETN
Offset: 0x8
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								CSI2_RESETN
Access								R/W
Reset								0

Bit 0 – CSI2_RESETN Internal Controller Logic Reset

Value	Description
0	Resets the internal controller logic.
1	CSI exits Reset state.

© 2026 Microchip Technology Inc. and its subsidiaries

50.7.3. CSI Main Interrupt Status Register

Name: CSI_INT_ST_MAIN
Offset: 0xC
Reset: 0x00000000
Property: Read-only

The following configuration values are valid for all listed bit names of this register:

0: No event occurred in the corresponding register since the last CSI_INT_ST_MAIN read.

1: An event occurred in the corresponding register since the last CSI_INT_ST_MAIN read.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
							STATUS_INT_LINE	STATUS_INT_DPHY
Access							R	R
Reset							0	0

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	STATUS_INT_ECC_CORRECTED	STATUS_INT_DATA_ID	STATUS_INT_PLD_CRC_FATAL	STATUS_INT_CRC_FRAME_FATAL	STATUS_INT_SEQ_FRAME_FATAL	STATUS_INT_BNDRY_FRAME_FATAL	STATUS_INT_PKT_FATAL	STATUS_INT_PHY_FATAL
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit 17 – STATUS_INT_LINE CSI_INT_ST_LINE Register Event (cleared on read)

Bit 16 – STATUS_INT_DPHY CSI_INT_ST_DPHY Register Event (cleared on read)

Bit 7 – STATUS_INT_ECC_CORRECTED STATUS_INT_ECC_CORRECTED Register Event (cleared on read)

Bit 6 – STATUS_INT_DATA_ID STATUS_INT_DATA_ID Register Event (cleared on read)

Bit 5 – STATUS_INT_PLD_CRC_FATAL STATUS_INT_PLD_CRC_FATAL Register Event (cleared on read)

Bit 4 – STATUS_INT_CRC_FRAME_FATAL STATUS_INT_CRC_FRAME_FATAL Register Event (cleared on read)

Bit 3 – STATUS_INT_SEQ_FRAME_FATAL STATUS_INT_SEQ_FRAME_FATAL Register Event (cleared on read)

Bit 2 – STATUS_INT_BNDRY_FRAME_FATAL CSI_INT_ST_BNDRY_FRAME_FATAL Register Event (cleared on read)

Bit 1 – STATUS_INT_PKT_FATAL CSI_INT_ST_PKT_FATAL Register Event (cleared on read)

Bit 0 – STATUS_INT_PHY_FATAL CSI_INT_ST_PHY_FATAL Register Event (cleared on read)

50.7.8. CSI D-PHY Shutdown Register

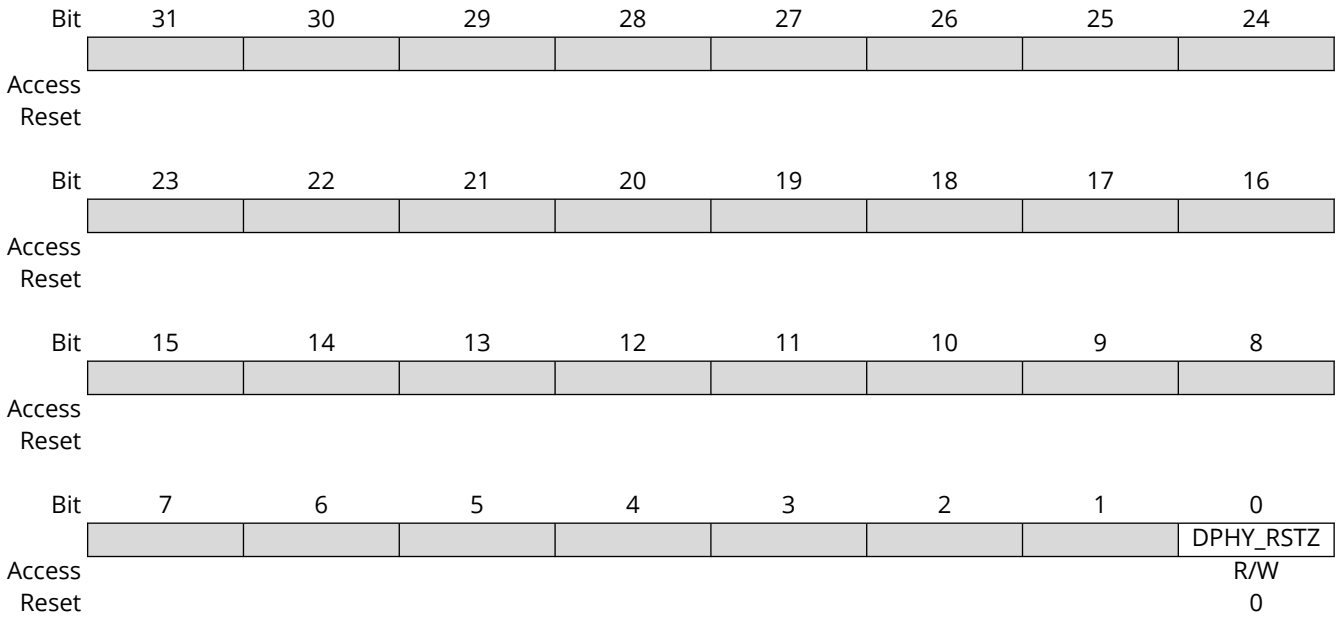
Name: CSI_PHY_SHUTDOWNZ
Offset: 0x40
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								PHY_SHUTDOWNZ
Access								R/W
Reset								0



Bit 0 – PHY_SHUTDOWNZ Shutdown Input Buffer

Value	Description
0	Puts the D-PHY in Shutdown mode. All analog blocks are in Power-down mode and digital logic is cleared.
1	D-PHY exits Shutdown mode.

© 2026 Microchip Technology Inc. and its subsidiaries

50.7.9. CSI D-PHY Reset Register

Name: CSI_DPHY_RSTZ
Offset: 0x44
Reset: 0x00000000
Property: Read/Write

Bit 0 – DPHY_RSTZ D-PHY Reset Control

Value	Description
0	Resets the D-PHY.
1	D-PHY exits Reset state.

© 2026 Microchip Technology Inc. and its subsidiaries

50.7.10. CSI D-PHY Receive Status Register

Name: CSI_PHY_RX
Offset: 0x48
Reset: 0x00010000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
							PHY_RXCLKACTIVEHS	PHY_RXULPSCLKNOT
Access							R	R
Reset							0	1

Bit	15	14	13	12	11	10	9	8
Access

Bit	7	6	5	4	3	2	1	0
					PHY_RXULPSESC_3	PHY_RXULPSESC_2	PHY_RXULPSESC_1	PHY_RXULPSESC_0
Access					R	R	R	R
Reset					0	0	0	0

Bit 17 – PHY_RXCLKACTIVEHS D-PHY Receives a DDR Clock

Value	Description
0	No DDR clock received.
1	The D-PHY clock lane is actively receiving a DDR clock.

Bit 16 – PHY_RXULPSSCLKNOT Clock Lane Power Status

Value	Description
0	The D-PHY Clock Lane module has entered ULP mode.
1	Clock Lane is not in ULP mode.

Bit 3 – PHY_RXULPSESC_3 Data Lane 3 Ultra-Low-Power Status

Value	Description
0	Data lane 3 module is not in ULP mode.
1	Data lane 3 module has entered ULP mode.

Bit 2 – PHY_RXULPSESC_2 Data Lane 2 Ultra-Low-Power Status

Value	Description
0	Data lane 2 module is not in ULP mode.
1	Data lane 2 module has entered ULP mode.

Bit 1 – PHY_RXULPSESC_1 Data Lane 1 Ultra-Low-Power Status

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	Data lane 1 module is not in ULP mode.
1	Data lane 1 module has entered ULP mode.

Bit 0 – PHY_RXULPSESC_0 Data Lane 0 Ultra-Low-Power Status

Value	Description
0	Data lane 0 module is not in ULP mode.
1	Data lane 0 module has entered ULP mode.

Reset					0	0	0	0

Bit 16 – PHY_STOPSTATECLK Clock Lane Stop State Status

Value	Description
0	Clock lane module is not in Stop state.
1	Clock lane module is in Stop state.

Bit 3 – PHY_STOPSTADATA_3 Data Lane 3 Stop State Status

Value	Description
0	Data lane 3 module is not in Stop state.
1	Data lane 3 module has entered Stop state.

Bit 2 – PHY_STOPSTADATA_2 Data Lane 2 Stop State Status

Value	Description
0	Data lane 2 module is not in Stop state.
1	Data lane 2 module has entered Stop state.

Bit 1 – PHY_STOPSTADATA_1 Data Lane 1 Stop State Status

Value	Description
0	Data lane 1 module is not in Stop state.
1	Data lane 1 module has entered Stop state.

Bit 0 – PHY_STOPSTADATA_0 Data Lane 0 Stop State Status

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	Data lane 0 module is not in Stop state.
1	Data lane 0 module has entered Stop state.

50.7.12. CSI D-PHY Analog Configuration Control Register

Name: CSI_PHY_TEST_CTRL0
Offset: 0x50
Reset: 0x00000001
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							PHY_TESTCLK	PHY_TESTCLR
Access							R/W	R/W
Reset							0	1

Bit 1 – PHY_TESTCLK Analog Configuration Control Clock
The data is loaded on one edge of PHY_TESTCLK, thus it is mandatory to write a '0' immediately after writing a '1'. Refer to PHY_TEST_CTRL1.PHY_TESTDEN.

Value	Description
0	No effect.
1	Captures the PHY_TEST_CTRL1.PHY_TESTDIN value.

Bit 0 – PHY_TESTCLR Analog Configuration Clear
The reset is performed on the rising edge of PHY_TESTCLR, thus it is mandatory to write a '0' immediately after writing a '1'.

Value	Description
0	No effect.
1	Resets the analog configuration.

© 2026 Microchip Technology Inc. and its subsidiaries

50.7.13. CSI D-PHY Analog Configuration Data Register

Name: CSI_PHY_TEST_CTRL1
Offset: 0x54
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
								PHY_TESTEN
Access								R/W
Reset								0

Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	PHY_TESTDIN[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 16 – PHY_TESTEN Analog Configuration Code Selection

Value	Description
0	Transmits the high-speed bit rate code on the rising edge of CSI_PHY_TEST_CTRL0.PHY_TESTCLK.
1	Transmits the address (0x44) of the high-speed bit rate code on the falling edge of CSI_PHY_TEST_CTRL0.PHY_TESTCLK.

Bits 15:8 – PHY_TESTDOUT[7:0] Read Data Output for Test
Data output for reading data and other probing functionalities.

Bits 7:0 – PHY_TESTDIN[7:0] Analog Configuration Value or High-Speed Bit Rate Code
Value selected by PHY_TESTEN.

© 2026 Microchip Technology Inc. and its subsidiaries

50.7.14. CSI Virtual Channel Extension Register

Name: CSI_VC_EXTENSION
Offset: 0xC8
Reset: 0x00000000
Property: Read/Write

Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								RXSKEWCALHS
Access								R
Reset								0

Bit 0 – RXSKEWCALHS Calibration Status (cleared on read)

Value	Description
0	No calibration initiated since the last CSI_PHY_CAL read.
1	A calibration has been initiated since the last CSI_PHY_CAL read.

© 2026 Microchip Technology Inc. and its subsidiaries

50.7.16. CSI D-PHY Fatal Error Interrupt Status Register

Name: CSI_INT_ST_PHY_FATAL
Offset: 0xE0
Reset: 0x00000000
Property: Read-only

Interrupt sources related to loss of synchronization in the D-PHY. Packet discarded.

Reading CSI_INT_ST_PHY_FATAL register does not clear the interrupt pin.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Access								
Reset								

Bit	7	6	5	4	3	2	1	0
					PHY_ERRSOTSYNCHS_3	PHY_ERRSOTSYNCHS_2	PHY_ERRSOTSYNCHS_1	PHY_ERRSOTSYNCHS_0
Access					R	R	R	R
Reset					0	0	0	0

Bit 3 – PHY_ERRSOTSYNCHS_3 Data Lane 3 Start Of Transmission Error Status (cleared on read)

Value	Description
0	No transmission error has occurred on data lane 3 since the last read of CSI_INT_ST_PHY_FATAL.
1	Transmission error has occurred on data lane 3 since the last read of CSI_INT_ST_PHY_FATAL.

Bit 2 – PHY_ERRSOTSYNCHS_2 Data Lane 2 Start Of Transmission Error Status (cleared on read)

Value	Description
0	No transmission error has occurred on data lane 2 since the last read of CSI_INT_ST_PHY_FATAL.
1	Transmission error has occurred on data lane 2 since the last read of CSI_INT_ST_PHY_FATAL.

Bit 1 – PHY_ERRSOTSYNCHS_1 Data Lane 1 Start Of Transmission Error Status (cleared on read)

Value	Description
0	No transmission error has occurred on data lane 1 since the last read of CSI_INT_ST_PHY_FATAL.
1	Transmission error has occurred on data lane 1 since the last read of CSI_INT_ST_PHY_FATAL.

Bit 0 – PHY_ERRSOTSYNCHS_0 Data Lane 0 Start Of Transmission Error Status (cleared on read)

Value	Description
0	No transmission error has occurred on data lane 0 since the last read of CSI_INT_ST_PHY_FATAL.
1	Transmission error has occurred on data lane 0 since the last read of CSI_INT_ST_PHY_FATAL.

© 2026 Microchip Technology Inc. and its subsidiaries

50.7.17. CSI D-PHY Fatal Error Interrupt Mask Register

Name: CSI_INT_MSK_PHY_FATAL
Offset: 0xE4
Reset: 0x00000000
Property: Read/Write

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is not enabled.

1: The corresponding interrupt is enabled.

Bit	31	30	29	28	27	26	25	24
Access								
Reset

Reset					0	0	0	0

Bit 3 – MASK_ERRSOTSYNCHS_3 Data Lane 3 Start Of Transmission Error Interrupt Mask

Bit 2 – MASK_ERRSOTSYNCHS_2 Data Lane 2 Start Of Transmission Error Interrupt Mask

Bit 1 – MASK_ERRSOTSYNCHS_1 Data Lane 1 Start Of Transmission Error Interrupt Mask

Bit 0 – MASK_ERRSOTSYNCHS_0 Data Lane 0 Start Of Transmission Error Interrupt Mask

© 2026 Microchip Technology Inc. and its subsidiaries

50.7.18. CSI D-PHY Fatal Error Interrupt Force Register

Name: CSI_INT_FORCE_PHY_FATAL
Offset: 0xE8
Reset: 0x00000000
Property: Read/Write

Used for test purposes. Triggers CSI_INT_ST_PHY_FATAL interrupt events individually without the need to activate the conditions that trigger the interrupt sources.

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: The corresponding interrupt source is forced.

Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit 3 – FORCE_ERRSOTSYNCHS_3 Force Start Of Transmission Interrupt Error on Data Lane 3

Bit 2 – FORCE_ERRSOTSYNCHS_2 Force Start Of Transmission Interrupt Error on Data Lane 2

Bit 1 – FORCE_ERRSOTSYNCHS_1 Force Start Of Transmission Interrupt Error on Data Lane 1

Bit 0 – FORCE_ERRSOTSYNCHS_0 Force Start Of Transmission Interrupt Error on Data Lane 0

© 2026 Microchip Technology Inc. and its subsidiaries

50.7.19. CSI Packet Fatal Error Interrupt Status Register

Name: CSI_INT_ST_PKT_FATAL
Offset: 0xF0
Reset: 0x00000000
Property: Read-only

Notifies which interrupt bit has caused the interruption.

Reading CSI_INT_ST_PKT_FATAL does not clear the interrupt pin.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								ERR_ECC_DOUBLE
Access								R
Reset								0

Bit 0 – ERR_ECC_DOUBLE Unrecoverable Header Error (ECC Two Errors) (cleared on read)

Value	Description
0	No event occurred since the last read of the register.
1	An event occurred since the last read of the register.

© 2026 Microchip Technology Inc. and its subsidiaries

50.7.20. CSI Packet Fatal Error Interrupt Mask Register

Name: CSI_INT_MSK_PKT_FATAL
Offset: 0xF4
Reset: 0x00000000
Property: Read/Write

The interrupt mask for CSI_INT_ST_PKT_FATAL controls which interrupt status bits trigger the interrupt pin.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

50.7.25. CSI Line Interrupt Status Register

Name: CSI_INT_ST_LINE
Offset: 0x130
Reset: 0x00000000
Property: Read-only

Reading the CSI_INT_ST_LINE register does not clear the interrupt pin.

The following configuration values are valid for all listed bit names of this register:

0: No event occurred since the last read of the register.

1: An event occurred since the last read of the register.

50.7.26. CSI Line Interrupt Mask Register

Name: CSI_INT_MSK_LINE
Offset: 0x134
Reset: 0x00000000
Property: Read/Write

The interrupt mask for CSI_INT_MSK_LINE controls which interrupt status bits trigger the interrupt pin.

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is not enabled.

1: The corresponding interrupt is enabled.

Bit	31	30	29	28	27	26	25	24

50.7.27. CSI Line Interrupt Force Register

Name: CSI_INT_FORCE_LINE
Offset: 0x138
Reset: 0x00000000
Property: Read/Write

Used for test purposes. Triggers CSI_INT_ST_LINE interrupt events individually without the need to activate the conditions that trigger the interrupt sources.

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is not enabled.

1: The corresponding interrupt is enabled.

50.7.28. CSI Boundary Frame Fatal Error Interrupt Status Register

Name: CSI_INT_ST_BNDRY_FRAME_FATAL
Offset: 0x280
Reset: 0x00000000
Property: Read/Write

Interrupt sources related to frame construction. Packet discarded. Reading CSI_INT_ST_FRAME_FATAL does not clear the interrupt pin.

The following configuration values are valid for all listed bit names of this register:

0: No event occurred since the last read of the register.

1: An event occurred since the last read of the register.

51. CSI-2 Demultiplexer Controller (CSI2DC)

51.1. Description

The CSI-2 Demultiplexer Controller (CSI2DC) receives incoming data from a CSI-2 physical interface and filters packets based on their data type and virtual channel identifier.

The CSI2DC is fed with four clock domains — the CSI-2 data clock domain, the ISC clock domain, the configuration clock domain and the system bus clock domain. The CSI2DC performs clock domain crossing of incoming packets.

The CSI2DC integrates one video pipeline and one data pipeline. The video pipeline converts the byte stream to a pixel stream with an optional RAW decompression algorithm. This pipeline is connected to the Image Sensor Controller (ISC). The data pipeline propagates the data packets to a system bus client interface. The data buffers are then processed by the processor or by the centralized Direct Memory Access (DMA) controller using DMA requests.

The CSI2DC also includes a snoop controller that captures image data and packet attributes helping system bring up and debug.

The table below summarizes acronyms used in the following sections.

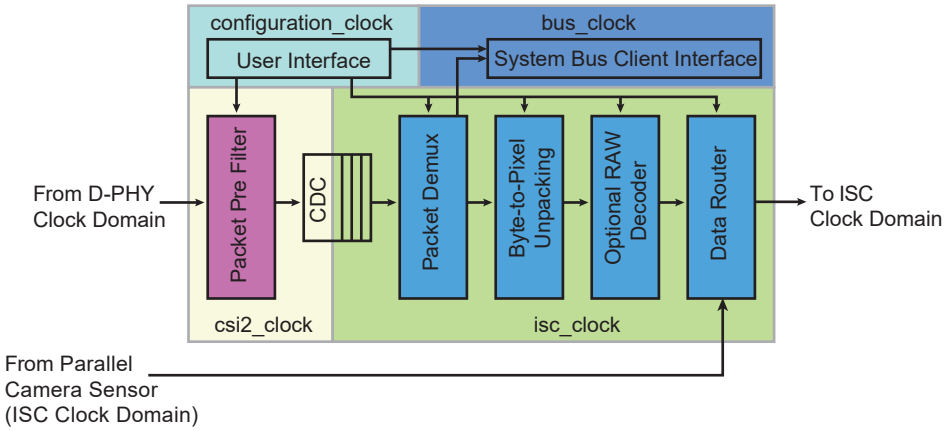
Table 51.1. Acronyms Used

CDC	Clock Domain Crossing
CSI	Camera Serial Interface
D-PHY	D Physical Layer
DMA	Direct Memory Access
DT	Data Type
FE	Frame End
FIFO	First In First Out
FS	Frame Start
GS	Generic Short
HS	High Speed; identifier for operation mode
ISC	Image Sensor Controller
ISP	Image Signal Processor
LE	Line End
LP	Low Power; identifier for operation mode
LS	Line Start
PFE	Parallel Front End
PHY	Physical Layer
RC	Row Count
RGB	Color representation (Red, Green, Blue)
SSP	Synchronization Short Packet
SW	Software
VC	Virtual Channel
WC	Word Count
YUV	Color representation (Y for luminance, U & V for chrominance)

51.2. Embedded Characteristics

- CSI-2 Version 1.3 Specification-compliant Demultiplexer
- Four Virtual Channels

© 2026 Microchip Technology Inc. and its subsidiaries



- Primary and Secondary Image Format
- RGB, YUV, RAW, Compressed RAW, User-defined Byte-based Packets
- Recommended Memory Storage Format or Single Pixel Per Clock Cycle
- Non-Image Data Packet and Generic Short Packet Support
- Image Data Snoop Controller (four entries)
- Programmable Video Pipeline Filter
- Programmable Data Pipeline Filter
- Progressive and Interlaced Content
- Programmable DMA Client Interface

51.3. Block Diagram

The CSI2DC includes four clocks:

- CSI-2 clock domain (CSI output): to sample the incoming byte stream along with protocol signals; up to 4 bytes per cycle are sampled.
- ISC clock domain (ISC peripheral clock): to extract pixels from the data packet; one pixel per clock cycle is retrieved in RGB or RAW mode.
- Configuration clock domain: for configuration and status
- System bus clock domain: to read data from the RAM

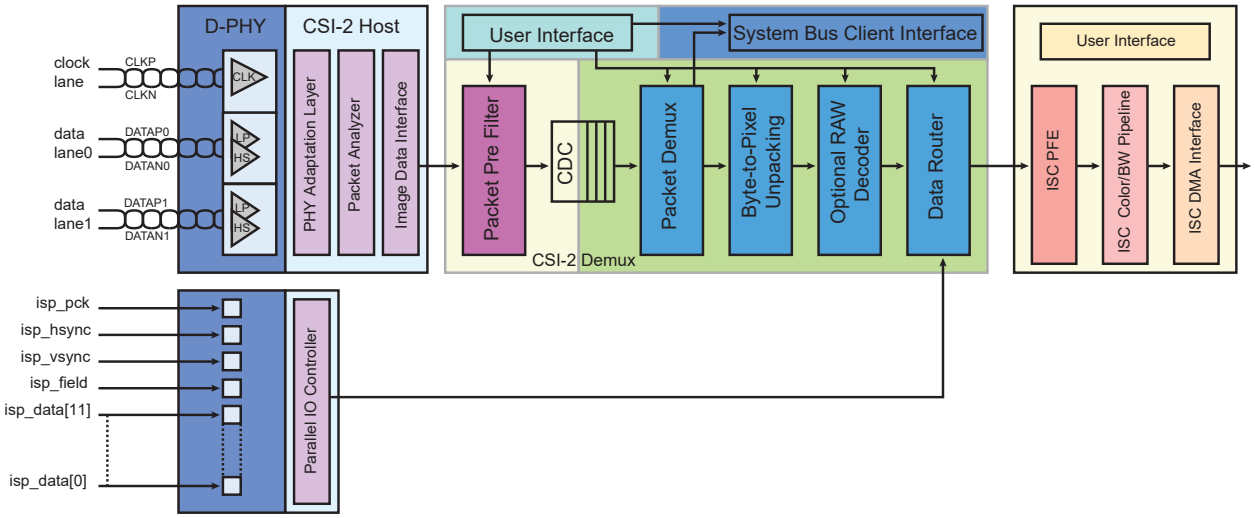
Table 51.2. I/O Lines Description (continued)



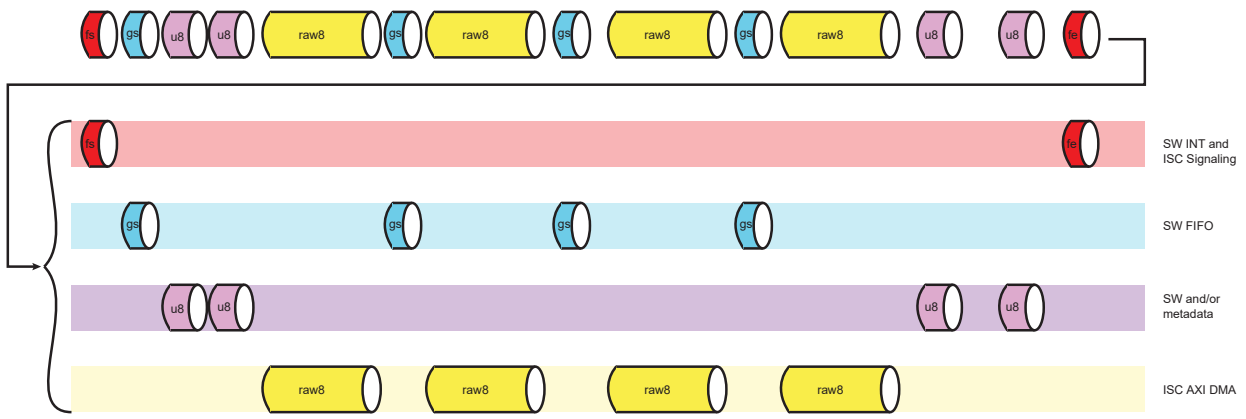
Signal Name	Description	Type
MIPI_REXT	Calibration reference resistor	Input/Output

51.5. Functional Description

As shown in the following figure, the CSI2DC is connected to a CSI-2 protocol host side. The host side receives data from a CSI-2-compliant camera. The supported host protocol, Image Data Interface (IDI), uses a 32-bit data bus, vertical and horizontal timing accurate video synchronization signals, data type and virtual channel.

The CSI2DC receives a packet-based data stream, and outputs a pixel stream through its video pipeline connected to the Image Sensor Controller.

Figure 51.2. CSI2DC System Integration



When a packet is received, a snoop controller can be used to monitor CSI-2 traffic and identify that the desired information is successfully transmitted and received in the CSI2DC.

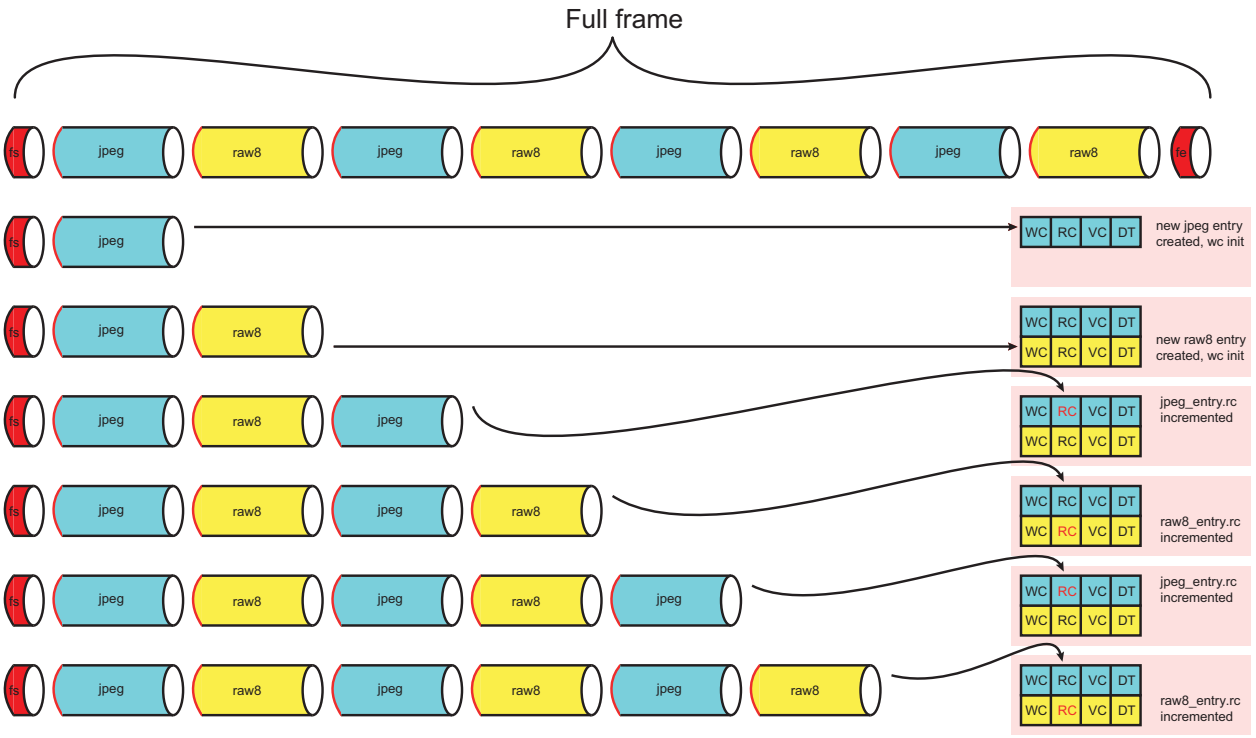
Once configured, the video pipe filters packets and transmits a predefined image data type. Only relevant packets are forwarded to the ISC clock domain. A buffer is used to adjust clock domain crossing between the CSI-2 host domain and the ISC clock domain. The video pipe must be enabled to route data from the camera to the ISC.

A system bus client port is also available to retrieve non-image data that are locally saved into buffers. The dual buffer operation can be used with centralized DMA assistance or by using CPU accesses. A simple queue is used to pass data packets from the CSI-2 host clock domain to the system bus clock domain. The packet is routed based on its data type.The data pipe must be enabled to route data from the camera to the system bus client interface.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 51.3. Packet Demultiplexing Example

51.5.1. Image Data Snoop (IDS) Controller



The Image Data Snoop Controller allows packet monitoring for system-level bring up and debug. When a new image data packet is received, a new entry is created. An entry is composed of the data type, the virtual channel identifier, the word count and the row count. When a new packet with the same virtual channel identifier and data type is received, the row count field is incremented. The table of entry is transferred at the end to the user interface for processor analysis.

Table 51.3. CSI2DC Image Data Snoop Controller

Packet	Data Type	Image Data Snoop Support
Generic Short Packet (GSP)	GSP code 1 to 8	No
Generic Long Packet (GLP)	Null or blanking data	Interrupt
	Embedded 8-bit non-image data	Yes
	Reserved	GLP error interrupt reserved
YUV Image Data	YUV	Yes
	Reserved	YUV error interrupt
RGB Image Data	RGB	Yes
	Reserved	RGB error interrupt
RAW Image Data	RAW 6 to 14	Yes
	Reserved	RAW error interrupt
User-defined 8-bit Data	User-defined 8-bit data types 1 to 8	Yes

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 51.4. Image Data Snoop Controller

51.5.2. Synchronization Short Packet Demux

Short packets include Frame Synchronization packets and Line Synchronization packets. Each image must begin with a Frame Start (FS) packet containing the Frame Start Code, and must end with a Frame End (FE) packet containing the Frame End code.

Table 51.4. Synchronization Short Packet Demultiplexing

Packet	Data Type	Handler
Synchronization Short Packet (SSP)	Frame Start Code	Per Virtual Channel Interrupt
	Frame End Code	Per Virtual Channel Interrupt
	Line Start Code (optional)	Per Virtual Channel Interrupt
	Line End Code (optional)	Per Virtual Channel Interrupt
	Reserved	SSP Error Interrupt reserved

The 16-bit frame number can be retrieved in the CSI2DC user interface. The Short Packet Data field indicates the frame number or the line number depending on the configuration. The behavior of the 16-bit frame number must be one of the following:

- Frame number is always 0, meaning that the frame number is inoperative.
- Frame number increments by 1 for every FS packet received with the same virtual channel identifier and is periodically reset to one, e.g. 1, 2, 1, 2, 1, 2 or 1, 2, 3, 4, 1, 2, 3, 4.
- The Frame number must be a non-value.

The behavior of the 16-bit line number must be one of the following:

- Line number is always zero — line number is inoperative.
- Line number increments by one for every Line Start (LS) packet received within the same virtual channel and the same data type. The line number is periodically reset to one for the first LS packet after a FS packet. The intended usage is for progressive scan.

© 2026 Microchip Technology Inc. and its subsidiaries

- Line number increments by same arbitrary step value greater than one for every LS packet with the same virtual channel and the same data type. The line number is periodically reset to a non-zero arbitrary start value for the first LS after an FS packet. The arbitrary start value may be different between successive frames. The intended usage is for interlaced video data.

51.5.3. Generic Short Packet Demux

Generic Short Packets (GSP) use the data type range [0x08, 0x0F]. These packets are retrieved through the CSI2DC user interface queue. An interrupt is raised as soon as the packet is received. The queue depth is set to 4 words. The data field retrieved is 22 bits wide and contains the 6-bit data type and a 16-bit data field. These values are passed to the application layer.

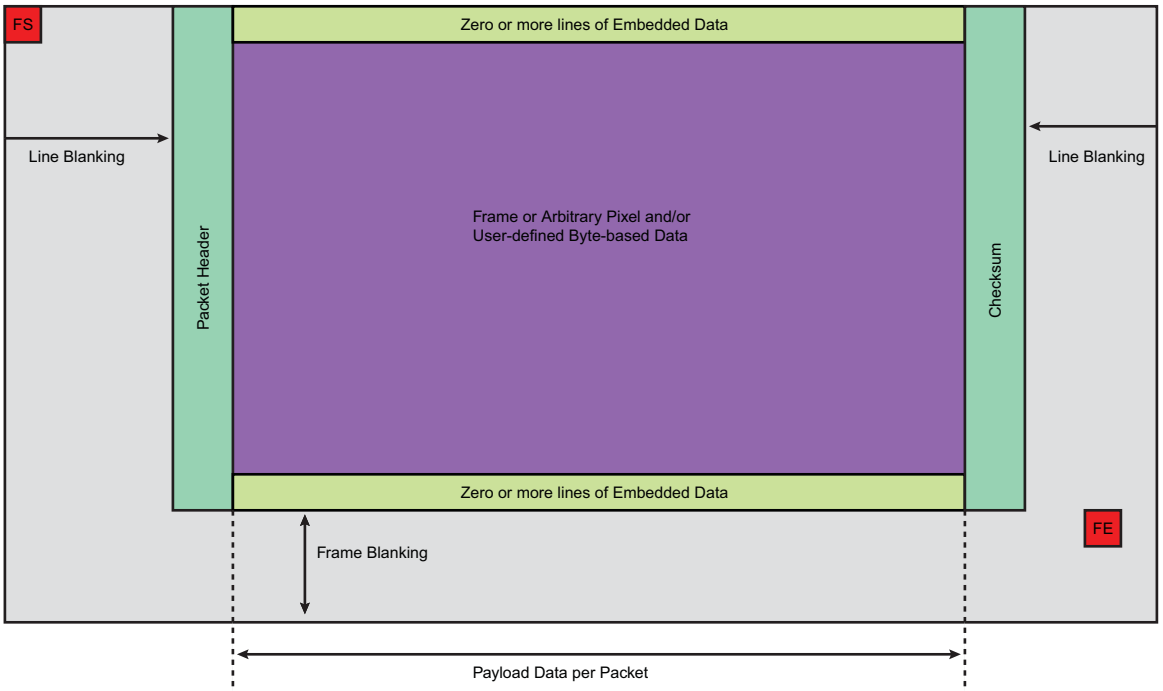
Table 51.5. Generic Short Packet Demultiplexing

Packet	Data Type	Handler
Generic Short Packet (GSP)	Code 1	Per Virtual Channel GSP queue
	Code 2	Per Virtual Channel GSP queue
	Code 3	Per Virtual Channel GSP queue
	Code 4	Per Virtual Channel GSP queue
	Code 5	Per Virtual Channel GSP queue
	Code 6	Per Virtual Channel GSP queue
	Code 7	Per Virtual Channel GSP queue
	Code 8	Per Virtual Channel GSP queue

51.5.4. Generic Long Packet Demux

The Generic Long Packet (GLP) contains three packet subclasses:

- NULL packet, data type set to 0x10
- Blanking data, data type set to 0x11
- Embedded 8-bit non-image data, data type set to 0x12



Null and blanking data packet content must be ignored by the application layer. Embedded 8-bit non-image data packets can be used to forward additional information from the camera to the host processor. These packets can be routed to the data pipe interface and read by the DMA interface or processor. The data payload must be a multiple of 8 bits.

Table 51.6. Generic Long Packet Demultiplexing

Packet	Data Type	Handler
Generic Long Packet (GLP)	Null	Null interrupt
	Blanking data	Data pipe
	Embedded 8-bit non-image data	Data pipe
	Reserved	GLP Error interrupt reserved

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 51.5. Generic Long Packet Embedded Information Packet

51.5.5. YUV Packet Demux

YUV data packets are always retrieved using the video pipe. CSI2DC reformats the stream to be compliant with the ISC video pipeline.

Table 51.7. YUV Image Data Demultiplexing

Packet	Data Type	Handler
YUV Image Data	YUV420 8-bit	Video pipe
	YUV420 10-bit	Video pipe
	Legacy YUV420 8-bit	Video pipe
	Reserved	YUV error interrupt
	YUV420 8-bit Chroma Shifted	Video pipe
	YUV420 10-bit Chroma Shifted	Video pipe
	YUV422 8-bit	Video pipe
	YUV422 10-bit	Video pipe

51.5.5.1. YUV 420 8-bit Legacy Mode

YUV 420 legacy data type is set to 0x1A.

Note: For this mode, ISC only supports 32-bit packed acquisition.

Pixel ID	P10[13:6]								P9[13:6]								P8[5:0]								P7[5:0]				P6[5:0]			
0x0C	q13	q12	q11	q10	q9	q8	q7	q6	p13	p12	p11	p10	p9	p8	p7	p6	h5	h4	h3	h2	h1	h0	g5	g4	g3	g2	g1	g0	f5	f4	f3	f2

51.5.8. User-Defined 8-bit Data

The User-Defined Data Type can be used to identify compressed data packets. CSI-2 specification indicates that a 12-7-12 compressed packet uses RAW7 data packing rule but the packet is tagged with User-Defined data type. The user-defined data type can be used to transmit arbitrary data such as JPEG or MPEG4.

© 2026 Microchip Technology Inc. and its subsidiaries

Table 51.50. User-Defined 8-bit Data Demultiplexing

Packet	Data Type	Handler
User-defined 8-bit Data	User-defined 8-bit data type 1	Video pipe
	User-defined 8-bit data type 2	Video pipe
	User-defined 8-bit data type 3	Video pipe
	User-defined 8-bit data type 4	Video pipe
	User-defined 8-bit data type 5	Video pipe
	User-defined 8-bit data type 6	Video pipe
	User-defined 8-bit data type 7	Video pipe
	User-defined 8-bit data type 8	Video pipe

For user-defined data:

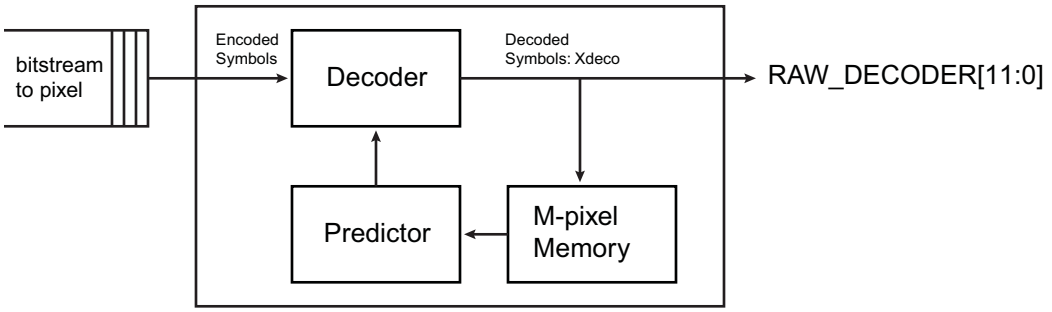
- The frame is transmitted as a sequence of arbitrarily-sized packets.
- The packet size may vary from packet to packet.
- Spacing between packets may vary.

51.5.9. CSI-2 Demux RAW Data Decompression Support

The CSI-2 implementation allows RAW data compression on the interface between the host processor and the camera module. Data compression schemes use an X-Y-Z naming convention where X is the number of bits per pixel in the original image, Y is the number of encoded (compressed) bits per pixel in the transmitted bit stream, and Z the number of decoded (uncompressed) bits per pixel.

Table 51.51. Decompression Mode Field Mapping to X-Y-Z Naming Convention

CSI2DC_VPCFG.DM	X-Y-Z CSI-2 Naming Rule
DECODER8TO12	12-8-12
DECODER7TO12	12-7-12
DECODER6TO12	12-6-12
DECODER8TO10	10-8-10
DECODER7TO10	10-7-10
DECODER6TO10	10-6-10



The data compression schemes specified in CSI-2 Annex E are lossy and are designed to encode each line independently.

Table 51.52. Decoder Output Formatting

CSI2DC_VPCFG.DM	RAW_DECODER[11:0]
DECODER8TO12	XDECO[11:0]
DECODER7TO12	XDECO[11:0]
DECODER6TO12	XDECO[11:0]
DECODER8TO10	XDECO[9:0]
DECODER7TO10	XDECO[9:0]
DECODER6TO10	XDECO[9:0]

51.6.1. CSI2DC Global Configuration Register

Name: CSI2DC_GCFGR
Offset: 0x00
Reset: 0x00000000
Property: Read/Write

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
	HLC[3:0]				SECDEDN	ULC	GPIOSEL	MIPIFRN
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 7:4 – HLC[3:0] CSI2DC Output Waveform Inter-line Minimum Delay
Inserts a minimal delay of (HLC+1) clock cycles between each line.

Bit 3 – SECDEDN Single Error Correction Double Error Detection Enable

Value	Description
0	Packet header error correction is activated.
1	Packet header error correction is disabled.

Bit 2 – ULC Use Optional Line Packet Delimiter

Value	Description
0	Line packets are not used to define the line boundary.
1	Line Start and Line End optional packets are used to activate and deactivate the line.

Bit 1 – GPIOSEL GPIO Parallel Interface Selection

Value	Description
0	The MIPI CSI-2 serial interface is activated.
1	The GPIO parallel interface is selected and internally routed to the Image Signal Processor.

Bit 0 – MIPIFRN MIPI Interface Free Running Clock

Value	Description
0	The sensor MIPI clock is free-running.
1	The sensor MIPI clock is gated.

Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								SWRST
Access								W
Reset								–

Bit 0 – SWRST Software Reset

Value	Description
0	No effect.
1	Starts a software reset operation.

© 2026 Microchip Technology Inc. and its subsidiaries

51.6.3. CSI2DC Global Status Register

Name: CSI2DC_GSR
Offset: 0x08
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							ARSTIP	RSTIP
Access							R	R
Reset							0	0

Bit 1 – ARSTIP Asynchronous Reset in Progress
This bit can be cleared only if the D-PHY clock is running.

Value	Description
0	No reset in progress for the asynchronous domain.
1	Asynchronous domain is being reset.

Bit 0 – RSTIP Reset in Progress

Value	Description
0	No reset in progress for the synchronous domain.
1	Synchronous domain is being reset.

51.6.4. CSI2DC Global Interrupt Enable Register

Name: CSI2DC_GIER
Offset: 0x0C
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

51.6.5. CSI2DC Global Interrupt Disable Register

Name: CSI2DC_GIDR
Offset: 0x10
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

51.6.6. CSI2DC Global Interrupt Mask Register

Name: CSI2DC_GIMR
Offset: 0x14
Reset: 0x00000000
Property: Read-only

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is masked.

1: The corresponding interrupt is activated.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Bit	7	6	5	4	3	2	1	0
	DED	SEC	DP	VP	IDS	GLP	GSP	SSP
Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bit 7 – DED Double Bit Error Detected Interrupt Status

Value	Description
0	No double bit error detected is pending.
1	A double bit error has been detected in the packet header. This bit is reset after the register read operation.

Bit 6 – SEC Single Bit Error Corrected Interrupt Status

Value	Description
0	No Single Bit Error Corrected interrupt is pending.
1	A single bit error has been detected and corrected in the packet header. This bit is reset after the register read operation.

Bit 5 – DP Data Pipe Interrupt Status

Value	Description
0	Either the interrupt source is masked at the DP level or no interrupt is pending for DP.
1	A Data Pipe interrupt is pending.

Bit 4 – VP Video Pipe Interrupt Status

Value	Description
0	Either the interrupt source is masked at the VP level or no interrupt is pending for VP.
1	A Video Pipe interrupt is pending.

Bit 3 – IDS Image Data Packet Snoop Controller Interrupt Status

Value	Description
0	Either the interrupt source is masked at the IDS level or no interrupt is pending for IDS.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	A new Image Data Packet interrupt is pending.

Bit 2 – GLP Generic Long Packet Interrupt Status

Value	Description
0	Either the interrupt source is masked at the GLP level or no interrupt is pending for GLP.
1	A Generic Long Packet interrupt is pending.

Bit 1 – GSP Generic Short Packet Interrupt Status

Value	Description
0	Either the interrupt source is masked at the GSP level or no interrupt is pending for GSP.
1	A Generic Short Packet interrupt is pending.

Bit 0 – SSP Synchronization Short Packet Interrupt Status

Value	Description
0	Either the interrupt source is masked at the SSP level or no interrupt is pending for SSP.
1	A Synchronization Short Packet interrupt is pending.

© 2026 Microchip Technology Inc. and its subsidiaries

51.6.8. CSI2DC SSP Interrupt Enable Register

Name: CSI2DC_SSPIER
Offset: 0x1C
Reset: –
Property: Write-only

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
					RE[3:0]			
Access					W	W	W	W
Reset					–	–	–	–

Bit	15	14	13	12	11	10	9	8
	LE[3:0]				LS[3:0]			
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

	FE[3:0]				FS[3:0]			
Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bits 19:16 – RE[3:0] Reserved Short Packet Interrupt Enable

Value	Description
0	No effect.
1	Setting a bit at position i in the RE field will set the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a Reserved Short Packet is detected.

Bits 15:12 – LE[3:0] Line End Interrupt Enable

Value	Description
0	No effect.
1	Setting a bit at position i in the LE field will set the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a Line End is detected. Line Synchronization packets are optional.

Bits 11:8 – LS[3:0] Line Start Interrupt Enable

Value	Description
0	No effect.
1	Setting a bit at position i in the LS field will set the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a Line Start is detected. Line Synchronization packets are optional.

Bits 7:4 – FE[3:0] Frame End Interrupt Enable

Value	Description
0	No effect.
1	Setting a bit at position i in the FE field will set the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a Frame End is detected.

Bits 3:0 – FS[3:0] Frame Start Interrupt Enable

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	No effect.
1	Setting a bit at position i in the FS field will set the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a Frame Start is detected.

© 2026 Microchip Technology Inc. and its subsidiaries

51.6.9. CSI2DC SSP Interrupt Disable Register

Name: CSI2DC_SSPIDR
Offset: 0x20
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Setting a bit at position i in this field clears the interrupt mask bit for virtual channel i.

Bit	31	30	29	28	27	26	25	24
Access

Access	R	R	R	R	R	R	R	R
Reset	0	0	0	0	0	0	0	0

Bits 19:16 – RE[3:0] Reserved Short Packet Interrupt Mask

Value	Description
0	A bit cleared at position i in the field RE indicates that the Reserved Packet interrupt is masked for virtual channel i.
1	A bit set at position i in field RE indicates that Reserved Packet interrupt is activated for virtual channel i.

Bits 15:12 – LE[3:0] Line End Interrupt Mask

Value	Description
0	A bit cleared at position i in the field LE indicates that the Line End interrupt is masked for virtual channel i.
1	A bit set at position i in field LE indicates that Line End interrupt is activated for virtual channel i.

Bits 11:8 – LS[3:0] Line Start Interrupt Mask

Value	Description
0	A bit cleared at position i in the field LS indicates that the Line Start interrupt is masked for virtual channel i.
1	A bit set at position i in field LS indicates that Line Start interrupt is activated for virtual channel i.

Bits 7:4 – FE[3:0] Frame End Interrupt Mask

Value	Description
0	A bit cleared at position i in the field FE indicates that the Frame End interrupt is masked for virtual channel i.
1	A bit set at position i in field FE indicates that Frame End interrupt is activated for virtual channel i.

Bits 3:0 – FS[3:0] Frame Start Interrupt Mask

Value	Description
0	A bit cleared at position i in the field FS indicates that the Frame Start interrupt is masked for virtual channel i.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	A bit set at position i in field FS indicates that Frame Start interrupt is activated for virtual channel i.

Bits 19:16 – RE[3:0] Reserved Short Packet Interrupt Status

Value	Description
0	A bit cleared at position i in the field RE indicates that no Reserved Short Packet interrupt is pending for virtual channel i.
1	A bit set at position i in the field RE indicates that no Reserved Short Packet interrupt is pending for virtual channel i. This bit is reset after the register read operation.

Bits 15:12 – LE[3:0] Line End Interrupt Status

Value	Description
0	A bit cleared at position i in the field LE indicates that no Line End interrupt is pending for virtual channel i.
1	A bit set at position i in the field LE indicates that a Line End interrupt is pending for virtual channel i. This bit is reset after the register read operation.

Bits 11:8 – LS[3:0] Line Start Interrupt Status

Value	Description
0	A bit cleared at position i in the field LS indicates that no Line Start interrupt is pending for virtual channel i.
1	A bit set at position i in the field LS indicates that a Line Start interrupt is pending for virtual channel i. This bit is reset after the register read operation.

Bits 7:4 – FE[3:0] Frame End Interrupt Status

Value	Description
0	A bit cleared at position i in the field FE indicates that no Frame End interrupt is pending for virtual channel i.
1	A bit set at position i in the field FE indicates that a Frame End interrupt is pending for virtual channel i. This bit is reset after the register read operation.

© 2026 Microchip Technology Inc. and its subsidiaries

Bits 3:0 – FS[3:0] Frame Start Interrupt Status

Value	Description
0	A bit cleared at position i in the field FS indicates that no Frame Start interrupt is pending for virtual channel i.
1	A bit set at position i in the field FS indicates that a Frame Start interrupt is pending for virtual channel i. This bit is reset after the register read operation.

Access	W	W	W	W	W	W	W	W
Reset	–	–	–	–	–	–	–	–

Bits 15:12 – RE[3:0] Reserved Packet Interrupt Enable Bit

Value	Description
0	No effect.
1	Setting a bit at position i in the RE field sets the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a reserved long packet is detected. A reserved long packet includes data types from 0x13 to 0x17.

Bits 11:8 – EB[3:0] Embedded 8-bit Non-Image Data Interrupt Enable Bit

Value	Description
0	No effect.
1	Setting a bit at position i in the EB field sets the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a non-image data packet is detected.

Bits 7:4 – BL[3:0] Blanking Data Interrupt Enable Bit

Value	Description
0	No effect.
1	Setting a bit at position i in the BL field sets the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a Blank packet is detected.

Bits 3:0 – NU[3:0] Null Interrupt Enable Bit

Value	Description
0	No effect.
1	Setting a bit at position i in the NU field sets the interrupt mask bit for virtual channel i, and this virtual channel can generate an interrupt when a null long packet is detected.

© 2026 Microchip Technology Inc. and its subsidiaries

51.6.29. CSI2DC GLP Interrupt Disable Register

Name: CSI2DC_GLPIDR
Offset: 0x80
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Setting a bit at position i in this field clears the interrupt mask bit for Virtual Channel i.

Bit	31	30	29	28	27	26	25	24

Reset	0	0	0	0	0	0	0	0

Bits 15:12 – RE[3:0] Reserved Packet Interrupt Mask Bit

Value	Description
0	A bit cleared at position i in the field RE indicates that the Reserved Packet interrupt is masked for virtual channel i.
1	A bit set at position i in field NU indicates that the Reserved Packet interrupt is activated for virtual channel i.

Bits 11:8 – EB[3:0] Embedded 8-bit Non-Image Data Packet Interrupt Mask Bit

Value	Description
0	A bit cleared at position i in the field EB indicates that the embedded data packet interrupt is masked for virtual channel i.
1	A bit set at position i in field EB indicates that the embedded data packet interrupt is activated for virtual channel i.

Bits 7:4 – BL[3:0] Blanking Data Packet Interrupt Mask Bit

Value	Description
0	A bit cleared at position i in the field BL indicates that the Blanking Data Packet interrupt is masked for virtual channel i.
1	A bit set at position i in field BL indicates that the Blanking Data Packet interrupt is activated for virtual channel i.

Bits 3:0 – NU[3:0] Null Packet Interrupt Mask Bit

Value	Description
0	A bit cleared at position i in the field NU indicates that the Null Packet interrupt is masked for virtual channel i.
1	A bit set at position i in field NU indicates that the Null Packet interrupt is activated for virtual channel i.

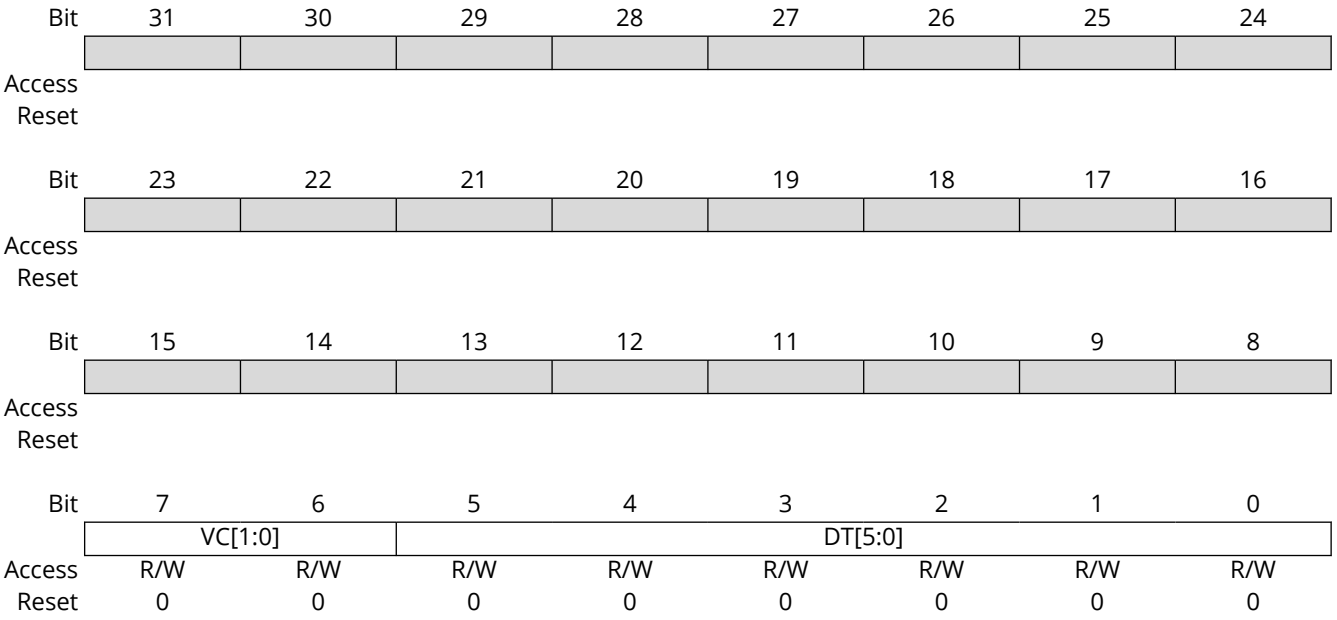
Bit 4 – OVF Image Data Snoop Overflow Interrupt Status

Value	Description
0	No effect.
1	Indicates that the IDS controller captured more than 4 entries. This bit is reset after the register read operation.



Bits 3:0 – IDS[3:0] Image Data Snoop Interrupt Status

Value	Description
0	A bit cleared at position i in the field IDS indicates that no Image Data Snoop interrupt is pending for virtual channel i.
1	A bit set at position i in the field IDS indicates that a new Image Data Snoop entry interrupt is pending for table entry i. This bit is reset after the register read operation.

Bit 1 – DP Data Pipe Attributes Update

Value	Description
0	No effect.
1	Transfers current configuration to Data Pipe Configuration registers on the next Frame Start Packet detection if the FS packet virtual channel ID matches the CSI2DC_DPCFG.VC field. This field must be set after data pipe configuration, otherwise the settings will not be updated.

Bit 0 – VP Video Pipe Attributes Update

Value	Description
0	No effect.
1	Transfers current configuration to Video Pipe Configuration registers on the next Frame Start Packet detection if the FS packet virtual channel ID matches the CSI2DC_VPCFG.VC field. This field must be set after video pipe configuration, otherwise the settings will not be updated.

Bit 31 – SIP Synchronization In Progress

Value	Description
0	No synchronization pending.
1	Synchronization across clock domain boundary is in progress. If the MIPI interface clock is gated, the synchronization procedure will wait for the first valid MIPI packet to activate the receiver clock.

Bit 1 – DP Data Pipe Update

Value	Description
0	No data pipe in progress.
1	Data pipe configuration is in progress. This bit is cleared at the next frame start packet if the virtual channel identifier matches the CSI2DC_DPCFG.VC field.

Bit 0 – VP Video Pipe Update

Value	Description
0	No video pipe in progress.
1	Video pipe configuration is in progress. This bit is cleared at the next frame start packet if the virtual channel identifier matches the CSI2DC_VPCFG.VC field.

Bit 7 – LTE Packet Longer Than Expected

Value	Description
0	No LTE packet detected.
1	A packet has been received but the actual length is longer that the packet word count value.

Bit 6 – STE Packet Shorter Than Expected

Value	Description
0	No STE packet detected since the last clear operation of the register.
1	A packet has been received but the actual length is shorter that the packet word count value.

Bit 5 – DATOVF Data Overflow

Value	Description
0	No overflow detected since the last clear operation of the register.
1	Data overflow in the clock domain crossing FIFO.

Bit 4 – RXOVF1 Bank 1 Overflow

Value	Description
0	No overflow detected since the last clear operation of the register.
1	An overflow occurred in bank 1.

Bit 3 – RXOVF0 Bank 0 Overflow

Value	Description
0	No overflow detected since the last clear operation of the register.
1	An overflow occurred in bank 0.

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 2 – RXRDY1 Bank 1 Packet Received

Value	Description
0	No packet received in bank 1 since the last clear operation of the register.
1	A new packet has been captured in the data pipe.

Bit 1 – RXRDY0 Bank 0 Packet Received

Value	Description
0	No packet received in bank 0 since the last clear operation of the register.
1	A new packet has been captured in the data pipe.

Bit 0 – CAPTURE Captured Frame

Value	Description
0	No frame captured on the data pipe interface since the last clear operation of the register.
1	A new frame has been captured in the data pipe.

Bit 7 – LTE Packet Longer Than Expected Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the LTE interrupt.

Bit 6 – STE Packet Shorter Than Expected Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the STE interrupt.

Bit 5 – DATOVF Data Overflow Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the Data Overflow interrupt.

Bit 4 – RXOVF1 Bank 1 Packet Overflow Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the Bank 1 Packet Overflow interrupt.

Bit 3 – RXOVF0 Bank 0 Packet Overflow Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the Bank 0 Packet Overflow interrupt.

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 2 – RXRDY1 Bank 1 Packet Received Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the Bank 1 Packet Received interrupt.

Bit 1 – RXRDY0 Bank 0 Packet Received Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the Bank 0 Packet Received interrupt.

Bit 0 – CAPTURE Captured Frame Interrupt Clear Register

Value	Description
0	No effect.
1	Clears the Captured Frame interrupt.

52. Image Sensor Controller (ISC)

52.1. Description

The Image Sensor Controller (ISC) system manages incoming data from a parallel or MIPI sensor. It supports a single active interface. The parallel interface protocol can use a free-running clock or a gated clock strategy. It supports the ITU-R BT 656/1120 422 protocol with a data width of 8 bits or 10 bits and raw Bayer format. The internal image processor includes adjustable white balance, color filter array interpolation, color correction, gamma correction, defective pixel correction, green disparity correction, black level correction, edge adaptive level, horizontal and vertical downscaler, 12 bits to 10 bits compression, programmable color space conversion, horizontal and vertical chrominance subsampling module. The module also integrates a triple-channel Host DMA interface.

52.2. Embedded Characteristics

- MIPI CSI2 Interface Supported, Single Component per Clock Cycle or Recommended Memory Storage (RMS) Mode
- Parallel 12-bit Interface for Raw Bayer, YCbCr, Monochrome and JPEG Compressed Sensor Interface
- BT.601/656/1120 Video Interface Supported
- Progressive Systems and Segmented Frame Systems
- Raw Bayer, YCbCr, Luminance (Black and White) Pixel Format Supported
- Resolution up to 2560 x 1920
- Input Pixel Clock up to 266 MHz
- Camera Sensor Clock Generation for Parallel Interface
- Cropping
- Adjustable White Balance
- Raw Bayer Color Filter Array Interpolation
- Color Correction
- Gamma Correction
- Defective Pixel Correction
- Green Disparity Correction
- Black Level Correction
- Edge Adaptive Level
- Vertical And Horizontal Polyphase Downscaler, with 16 Phases and 4 Taps
- Color Space Conversion
- Contrast, Brightness, Hue and Saturation Control
- 4:4:4 to 4:2:2 Subsampler
- 4:2:2 to 4:2:0 Subsampler
- Rounding, Limiting and Packing unit
- Histogram Generation
- System Interface: Direct Memory Access Interface with Packed, Semi Planar and Planar output format
- Output Memory Format: 16 bpp RGB, 32 bpp RGB, 16 bpp, YCbCr 444, YCbCr 422, YCbCr 420, up to 14-bit Raw Bayer
- Register Write Protection

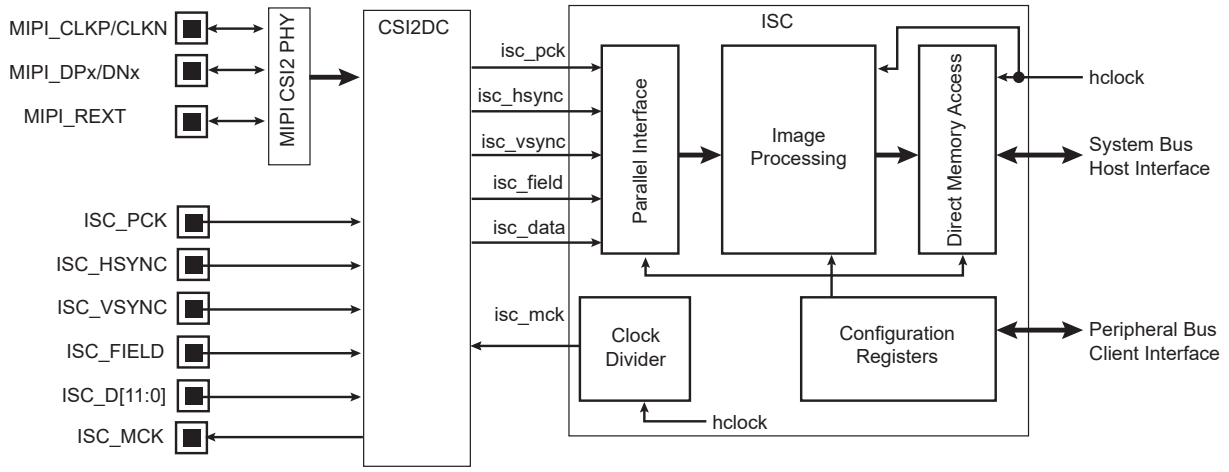
52.3. ISC Block Diagram and Use Cases

52.3.1. Functional Diagrams

Figure 52.1. ISC Block Diagram



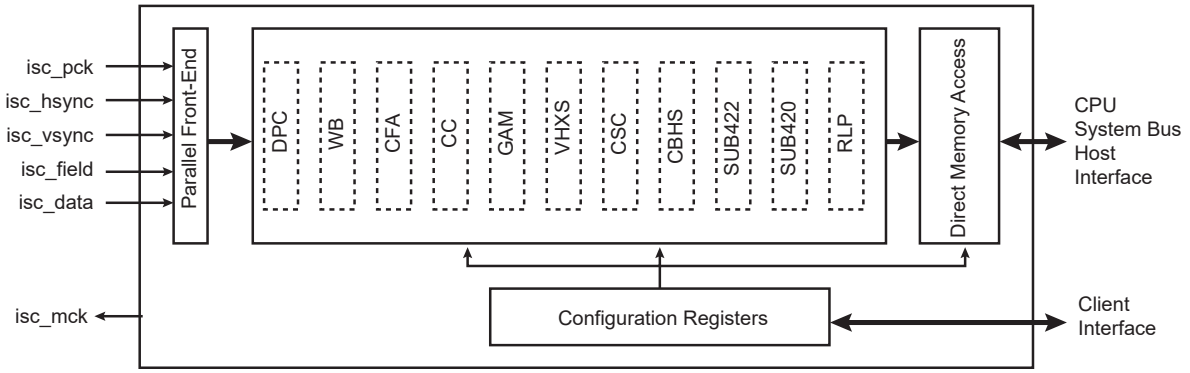


Figure 52.2. ISC Raw Bayer Signal Processor

The ISC video pipeline integrates the following submodules:

- DPC: Defective pixel correction, also including a Green Disparity Correction (GDC), Black Level Correction (BLC), Edge Adaptive Level (EAL)
- PFE: Parallel Front End to sample the camera sensor input stream
- WB: Programmable white balance in the Bayer domain
- CFA: Color filter array interpolation module
- CC: Programmable color correction
- GAM: Gamma correction
- VHXS: Vertical and horizontal scaling engine
- CSC: Programmable color space conversion
- CBHS: Performs contrast, brightness, hue and saturation control
- SUB422: Performs YCbCr444 to YCbCr422 chrominance horizontal subsampling
- SUB420: Performs YCbCr422 to YCbCr420 chrominance vertical subsampling
- RLP: Performs rounding, range limiting and packing of the incoming data.

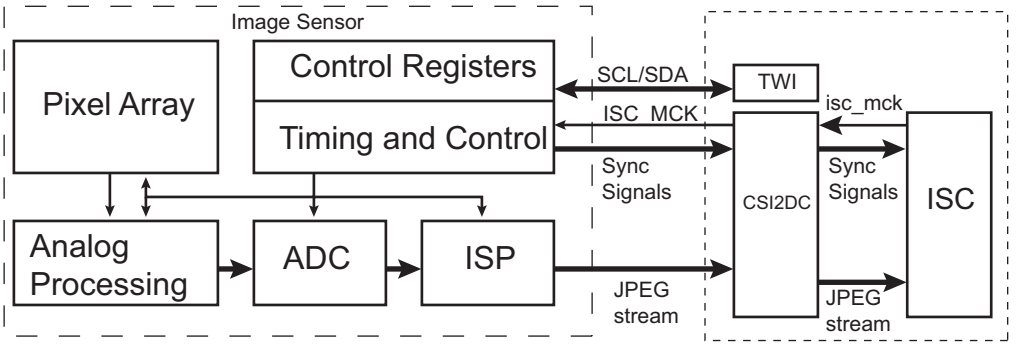
Figure 52.8. Sensor with JPEG Output



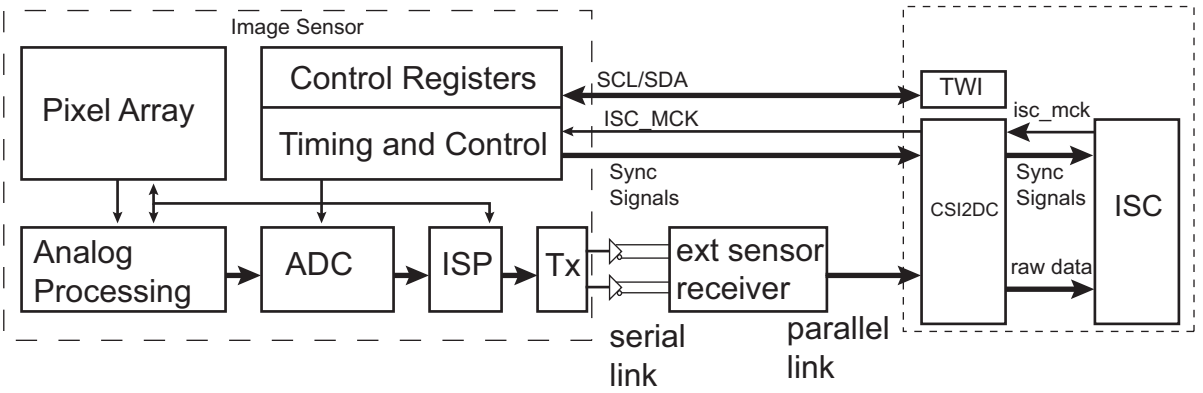


Figure 52.9. Serial CMOS Sensor with External Parallel Bridge

52.5. Product Dependencies

52.5.1. I/O Lines

The parallel interface pins used for interfacing the ISC are multiplexed with the PIO lines. The programmer must first program the PIO controller to assign the ISC pins to their peripheral function. If I/O lines of the ISC are not used by the application, they can be used for other purposes by the PIO controller.

When the MIPI link is used to interface the ISC, refer to the section "Camera Serial Interface (CSI)" to enable the MIPI inputs (not multiplexed with PIO lines).

52.5.2. Power Management

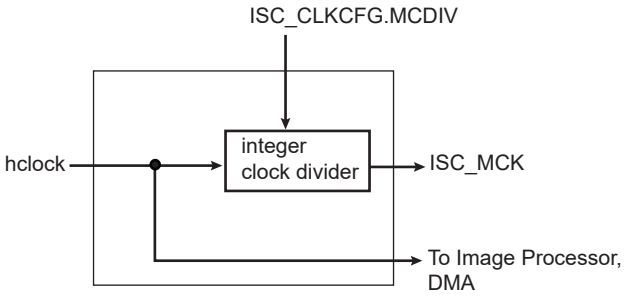
The ISC peripheral clock (hclock) is not continuously provided to the ISC. The programmer must first enable the ISC clock in the Power Management Controller (PMC) before using the ISC.

When the MIPI link is used to interface the ISC, refer to the sections "Camera Serial Interface (CSI)" to enable the MIPI PHY and "CSI-2 Demultiplexer Controller (CSI2DC)".

52.5.3. Interrupt Sources

The ISC interrupt line is connected on one of the internal sources of the Interrupt Controller. Using the ISC interrupt requires the Interrupt Controller to be programmed first.

© 2026 Microchip Technology Inc. and its subsidiaries



52.6. Functional Description

52.6.1. ISC Clock Management

The ISC module provides the ISC_MCK output clock to the CSI2 Demultiplexer Controller (CSI2DC), which transfers video stream from the MIPI CSI2 clock domain to the ISC_MCK clock domain. See the Block Diagram.

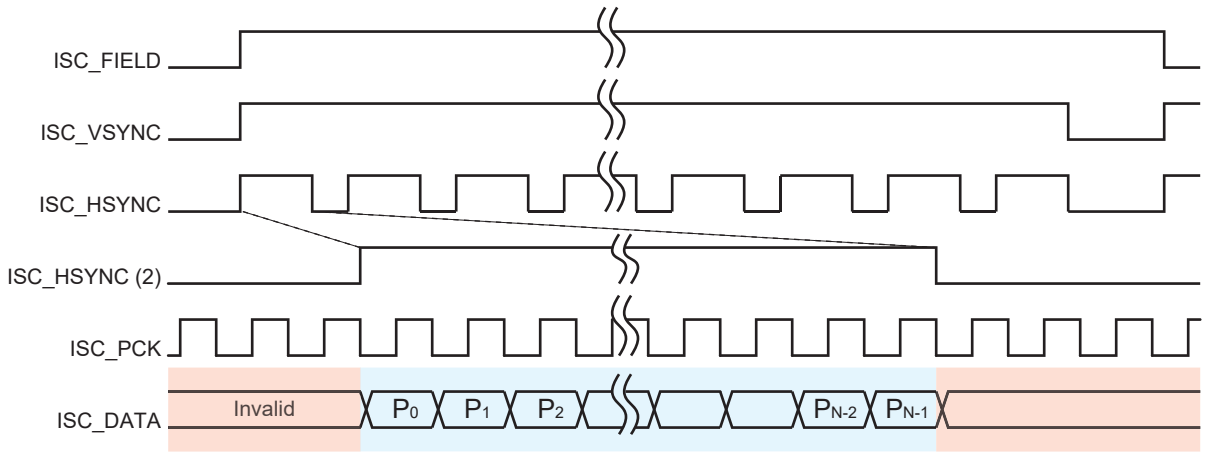
ISC_MCK has one programmable clock divider (ISC_CLKCFG.MCDIV). The clock is enabled using ISC_CLKEN.MCEN.

Figure 52.10. Clock Divider Block Diagram

The ISC is designed to accept input signals that are asynchronous to hclock.

Synchronization is done internally as long as the following relationship holds:

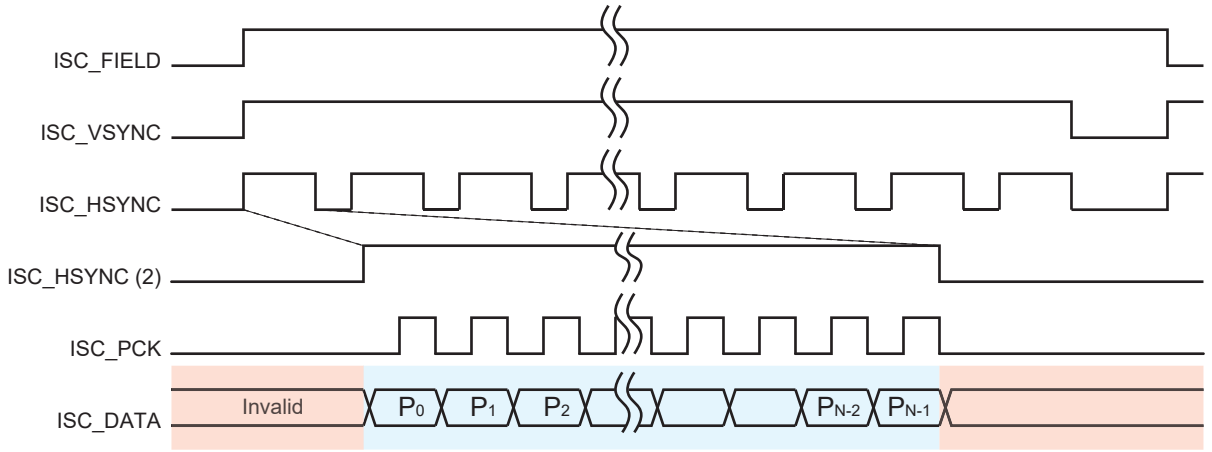
- isc_pck frequency is lower than or equal to hclock frequency.



52.6.1.1. Software Requirement

A software write operation to ISC_CLKEN or ISC_CLKDIS requires double clock domain synchronization and is not permitted when ISC_CLKSR.SIP is asserted.

52.6.2. Parallel Interface Timing Description



The parallel interface protocol supports two operating modes.

Figure 52.11. Free-Running Pixel Clock

© 2026 Microchip Technology Inc. and its subsidiaries

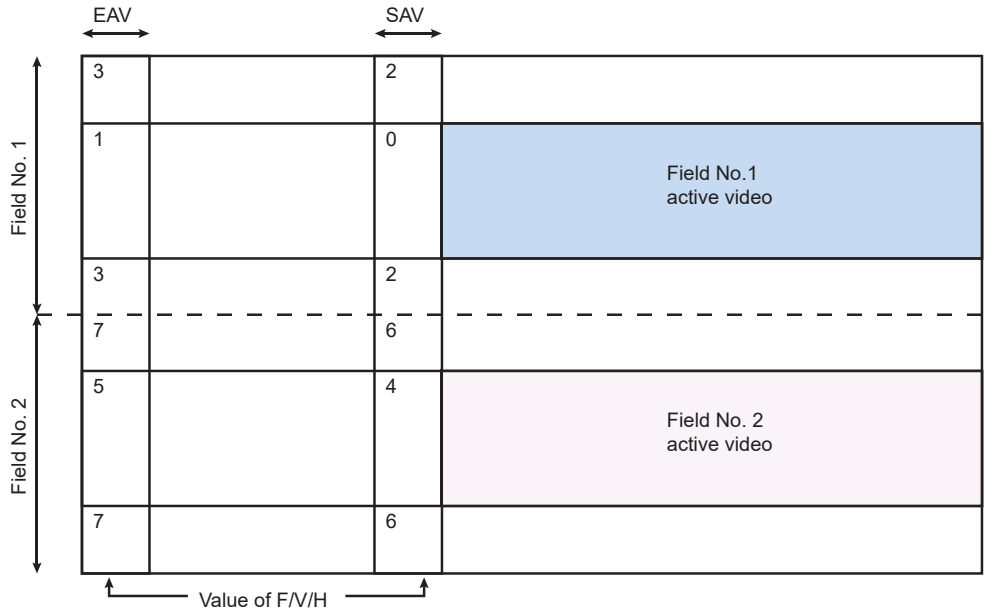


Figure 52.12. Gated Pixel Clock

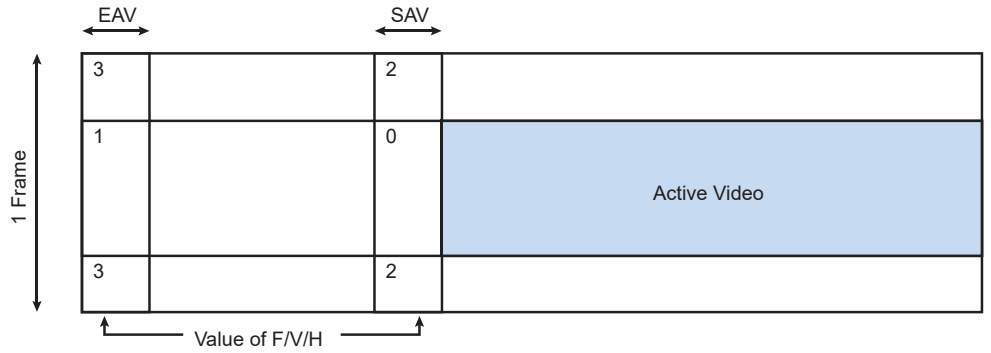
52.6.3. BT.601/656/1120 Embedded Timing Synchronization Operation



The ISC module supports embedded synchronization decoding. When ISC_PFE_CFG0.CCIR656 is set, the decoder is activated and signals isc_vsync and isc_hsync are not used to decode the valid pixels. If CCIR10_8N is set, the bitstream is 10 bits wide, otherwise it is only 8 bits wide. When ISC_PFE_CFG0.CCIR_CRC is set, the decoder automatically corrects the error.

Figure 52.13. Field/Segment Timing Relationship for Interlaced and Segmented Frame Systems

52.6.4.3. Raw Bayer Parallel Interface

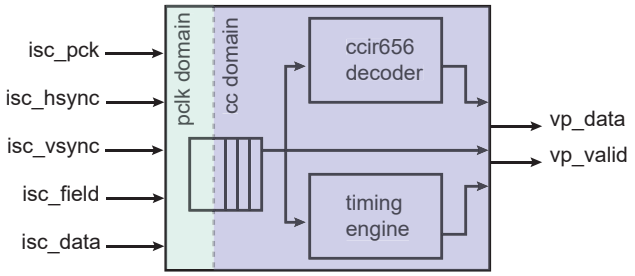
The table below shows how to connect the data bus of a raw Bayer sensor.

© 2026 Microchip Technology Inc. and its subsidiaries

Interface	Bayer 12-bit	Bayer 11-bit	Bayer 10-bit	Bayer 9-bit	Bayer 8-bit
ISC_DATA[11](MSB)	DOUT[11]	DOUT[10]	DOUT[9]	DOUT[8]	DOUT[7]
ISC_DATA[10]	DOUT[10]	DOUT[9]	DOUT[8]	DOUT[7]	DOUT[6]
ISC_DATA[9]	DOUT[9]	DOUT[8]	DOUT[7]	DOUT[6]	DOUT[5]
ISC_DATA[8]	DOUT[8]	DOUT[7]	DOUT[6]	DOUT[5]	DOUT[4]
ISC_DATA[7]	DOUT[7]	DOUT[6]	DOUT[5]	DOUT[4]	DOUT[3]
ISC_DATA[6]	DOUT[6]	DOUT[5]	DOUT[4]	DOUT[3]	DOUT[2]
ISC_DATA[5]	DOUT[5]	DOUT[4]	DOUT[3]	DOUT[2]	DOUT[1]
ISC_DATA[4]	DOUT[4]	DOUT[3]	DOUT[2]	DOUT[1]	DOUT[0]
ISC_DATA[3]	DOUT[3]	DOUT[2]	DOUT[1]	DOUT[0]	Not Used
ISC_DATA[2]	DOUT[2]	DOUT[1]	DOUT[0]	Not Used	Not Used
ISC_DATA[1]	DOUT[1]	DOUT[0]	Not Used	Not Used	Not Used
ISC_DATA[0]	DOUT[0]	Not Used	Not Used	Not Used	Not Used

52.6.4.4. Monochrome Parallel Interface

The table below shows how to connect the data bus of a Monochrome sensor.



Interface	Mono 12-bit	Mono 11-bit	Mono 10-bit	Mono 9-bit	Mono 8-bit
ISC_DATA[11](MSB)	DOUT[11]	DOUT[10]	DOUT[9]	DOUT[8]	DOUT[7]
ISC_DATA[10]	DOUT[10]	DOUT[9]	DOUT[8]	DOUT[7]	DOUT[6]
ISC_DATA[9]	DOUT[9]	DOUT[8]	DOUT[7]	DOUT[6]	DOUT[5]
ISC_DATA[8]	DOUT[8]	DOUT[7]	DOUT[6]	DOUT[5]	DOUT[4]
ISC_DATA[7]	DOUT[7]	DOUT[6]	DOUT[5]	DOUT[4]	DOUT[3]
ISC_DATA[6]	DOUT[6]	DOUT[5]	DOUT[4]	DOUT[3]	DOUT[2]
ISC_DATA[5]	DOUT[5]	DOUT[4]	DOUT[3]	DOUT[2]	DOUT[1]
ISC_DATA[4]	DOUT[4]	DOUT[3]	DOUT[2]	DOUT[1]	DOUT[0]
ISC_DATA[3]	DOUT[3]	DOUT[2]	DOUT[1]	DOUT[0]	Not Used
ISC_DATA[2]	DOUT[2]	DOUT[1]	DOUT[0]	Not Used	Not Used
ISC_DATA[1]	DOUT[1]	DOUT[0]	Not Used	Not Used	Not Used
ISC_DATA[0]	DOUT[0]	Not Used	Not Used	Not Used	Not Used

52.6.5. MIPI Interface Mapping

When operating with a MIPI interface, the CSI2DC maps the pixel content on the input data bus according to the data format. Refer to the Functional Description in the section “CSI-2 Demultiplexer Controller (CSI2DC)”.

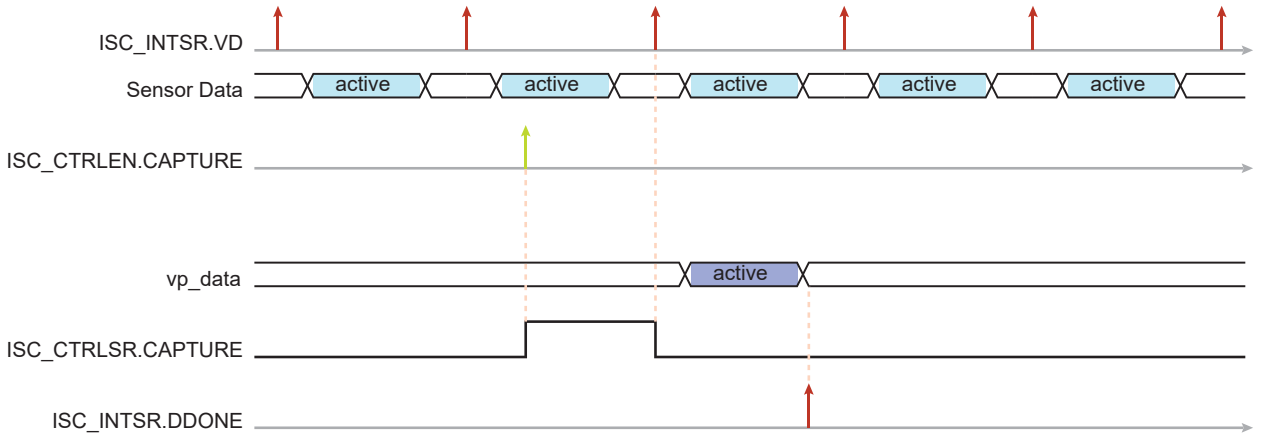
52.6.6. Parallel Front End (PFE) Module

Figure 52.15. PFE Block Diagram

© 2026 Microchip Technology Inc. and its subsidiaries

The Parallel Front End module performs data resampling across clock domain boundary. It includes a CCIR656 decoder used to convert a standard ITU-R BT.656 stream to 24-bit digital video. It also generates pixels, syncs flags and valid signals to the main video pipeline. It ouputs field, video and synchronization signals. The PFE can optionally crop and limit the incoming pixel stream to a predefined horizontal and vertical value. By default, the PFE only relies on the input horizontal and vertical references to sample the incoming pixel stream. A pixel is sampled if, and only if, the vertical and horizontal synchronizations are valid and a pixel clock edge is detected. ISC_PFE_CFG0.BPS shows the number of bits per sample.

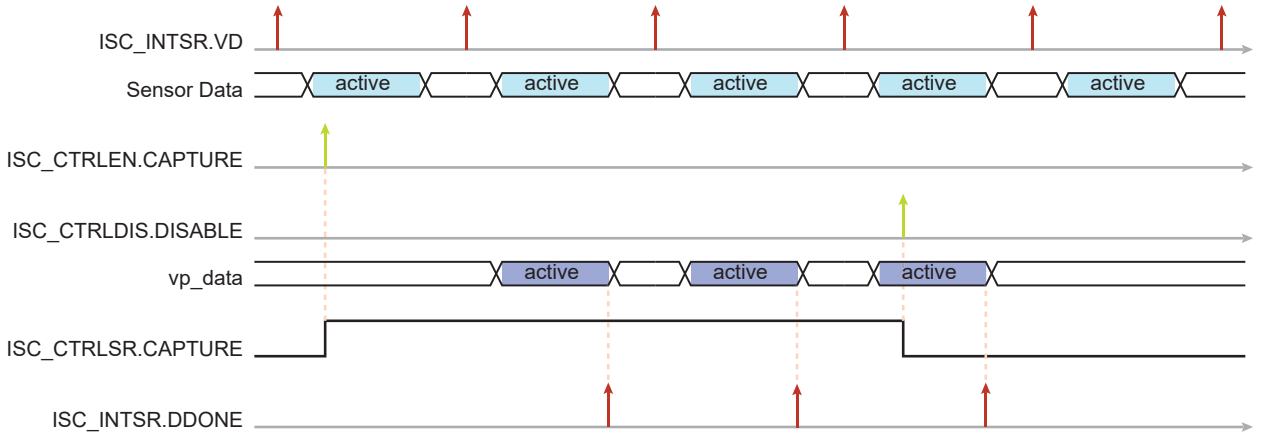
When operating with a parallel interface, the PFE module outputs a 12-bit data on the vp_data[11:0] bus, and asserts the vp_valid signal when the data can be sampled.



PFE vp_data Mapping	Raw Bayer 12-bit	Raw Bayer 10-bit	YUV422 8-bit	YUV422 10-bit	Mono 12-bit
vp_data[39:12]	–	–	–	–	–
vp_data[11]	RGGB[11]	RGGB[9]	YC422[7]	YC422[9]	Y[11]
vp_data[10]	RGGB[10]	RGGB[8]	YC422[6]	YC422[8]	Y[10]
vp_data[9]	RGGB[9]	RGGB[7]	YC422[5]	YC422[7]	Y[9]
vp_data[8]	RGGB[8]	RGGB[6]	YC422[4]	YC422[6]	Y[8]
vp_data[7]	RGGB[7]	RGGB[5]	YC422[3]	YC422[5]	Y[7]
vp_data[6]	RGGB[6]	RGGB[4]	YC422[2]	YC422[4]	Y[6]
vp_data[5]	RGGB[5]	RGGB[3]	YC422[1]	YC422[3]	Y[5]
vp_data[4]	RGGB[4]	RGGB[2]	YC422[0]	YC422[2]	Y[4]
vp_data[3]	RGGB[3]	RGGB[1]	YC422[7] or 0	YC422[1]	Y[3]
vp_data[2]	RGGB[2]	RGGB[0]	YC422[6] or 0	YC422[0]	Y[2]
vp_data[1]	RGGB[1]	RGGB[9] or 0	YC422[5] or 0	YC422[9] or 0	Y[1]
vp_data[0]	RGGB[0]	RGGB[8] or 0	YC422[4] or 0	YC422[8] or 0	Y[0]

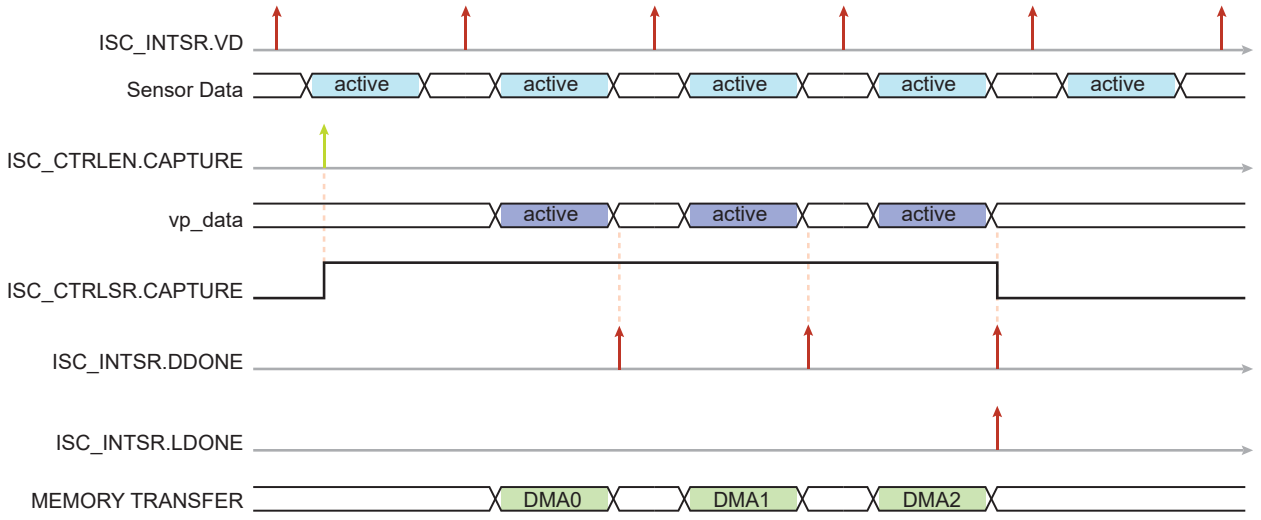
Note: When ISC_PFE_CFG0.REP is set, missing vp_data LSBs are replaced with replicated LSBs of the incoming stream, otherwise they are forced to zero.

When operating with MIPI RGB or YUV formats, the PFE module copies up to 40-bit data from isc_data[39:0] bus on the vp_data[39:0] bus, and asserts the vp_valid signal when the data can be sampled.



The PFE module also includes logic to synchronize capture request with the incoming pixel stream. Two operating modes are available: Single Shot and Continuous Acquisition. When ISC_PFE_CFG0.CONT is cleared, the ISC transfers a single image to memory,

Figure 52.16. Single Shot Mode



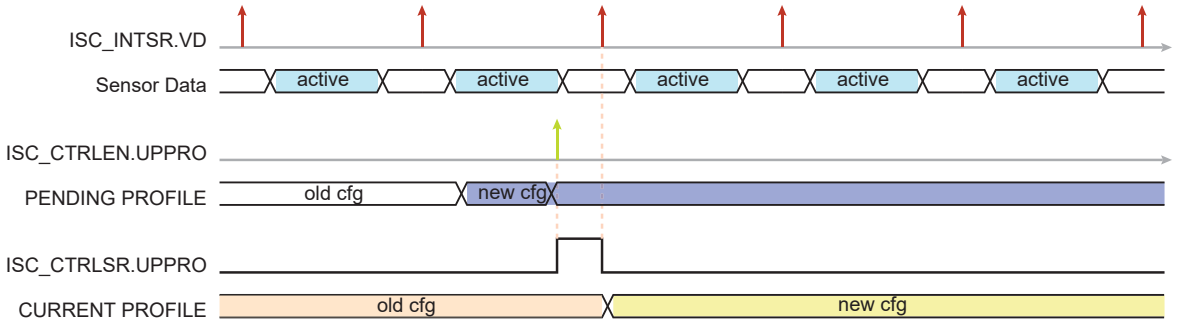
© 2026 Microchip Technology Inc. and its subsidiaries

Figure 52.17. Continuous Acquisition Mode

When Continuous Acquisition mode is activated (ISC_PFE_CFG0.CONT is set), the data transfer terminates when either a DMA end of list is reached, a software disable is performed or a software reset is activated. ISC_INTSR.DDONE is set at the end of the DMA data transfer.

Figure 52.18. Continuous Acquisition, DMA Terminated

The linked list DMA transfer is terminated when an item of the list is programmed with ISC_DCTRL.DE cleared or when ISC_DNDA.NDA is equal to zero. This configuration also clears ISC_CTRLSR.CAPTURE and sets the ISC_INTSR.LDONE interrupt flag.



The linked list DMA transfer starts if ISC_DCTRL.DE is set and if ISC_DNDA.NDA is different from zero.

52.6.6.1. Update the ISC Profile

Each ISC register is double-buffered to simplify the software configuration and the synchronization with the associated frame buffer. When the configuration of the ISC is modified, ISC_CTRLEN.UPPRO must be set to transfer the configuration from the input buffer to the ISC video pipeline.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 52.19. Update Profile Timing Diagram

52.6.6.2.Software Requirements

Writing to ISC_CTRLEN or ISC_CTRLDIS requires a double domain synchronization, so it is forbidden to write these registers when ISC_CTRLSR.SIP is asserted.

52.6.7. Defective Pixel Correction (DPC)

The ISC can detect and correct defective pixels on Raw Bayer formats up to 12-bit width. The defective pixel correction is enabled by writing '1' to ISC_DPC_CTRL.DPCEN.

The color filter array pattern of the image sensor driven by ISC must be configured in ISC_DPC_CFG.BAYCFG.

It is possible to adjust the processing performed by the defective pixel correction logic.

Several criteria can be activated to determine if a pixel is defective (edge interpolation, median threshold, closest pixel, average threshold).

The edge interpolation is enabled by writing ISC_DPC_CFG.EITPOL=1.

The median threshold is enabled by writing ISC_DPC_CFG.TM_ENABLE=1.

The closest pixel threshold is enabled by writing ISC_DPC_CFG.TC_ENABLE=1.

The average threshold is enabled by writing ISC_DPC_CFG.TA_ENABLE=1.

The different thresholds can be configured in ISC_DPC_THRESHM.THRESHM, ISC_DPC_THRESHC.THRESHC, ISC_DPC_THRESHA.THRESHA.

The triggering of a pixel correction can be triggered when all active criteria are met or only one is met by configuring the bit ISC_DPC_CFG.ND_MODE.

The number of corrected pixels by frame are reported in ISC_DPC_SR.COUNTER.

52.6.8. Green Disparity Correction (GDC)

The color filter array pattern alternates horizontal lines made of green and blue pixels with lines made of green and red pixels.

This pattern introduces green disparity from line to line that can automatically corrected by writing a '1' in ISC_DPC_CTRL.GDCEN.

The green disparity clipping value must be configured in ISC_DPC_CFG.GDCCLP.

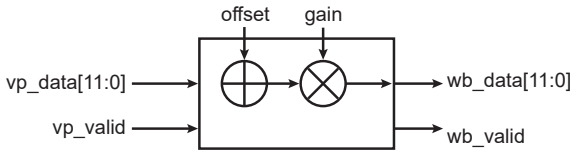
The GDC module operates on Raw Bayer formats up to 12-bit width.

52.6.9. Black Level Correction (BLC)

The black level provided by the image sensor is automatically corrected if ISC_DPC_CTRL.BLCEN=1.

The black level offset provided by the image sensor (refer to the image sensor reference manual) must be configured in ISC_DPC_CFG.BLOFST.

© 2026 Microchip Technology Inc. and its subsidiaries



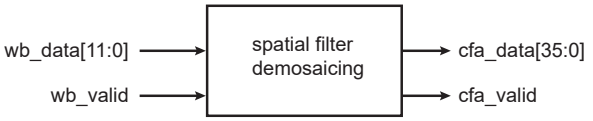
The BLC module operates on Raw Bayer formats up to 12-bit width.

52.6.10. White Balance (WB) Module

The White Balance (WB) module captures the vp_data bus from the PFE module when the vp_valid signal is asserted, and it generates a wb_data data along with its validity signal wb_valid.

When operating with Raw Bayer formats, and ISC_WB_CTRL.ENABLE is set (up to 12-bit width supported), each Bayer color component (R, Gr, B, Gb) can be manually adjusted using an offset and a gain. The Bayer pattern is adjustable using ISC_WB_CFG.BAYCFG.

Figure 52.20. WB Block Diagram



There are four {gain, offset} sets for each component. The output value is clipped.

ISC_WB_CTRL.ENABLE	WB_DATA Slice	Value
0	wb_data[11:0]	vp_data[11:0]
1	wb_data[11:0]	clipped((vp_data[11:0]+offset)*gain)

52.6.11. Color Filter Array (CFA) Interpolation Module

In a single-sensor system, each cell on the sensor has a specific color filter and microlens positioned above it. The raw data obtained from the sensor do not have the full R/G/B information at each cell position. Color interpolation is required to retrieve the missing components. The CFA module samples the wb_data[11:0] 12-bit bus when wb_valid is asserted and generates a 36-bit width data bus cfa_data[35:0] with the validity bit cfa_valid.

Figure 52.21. CFA Block Diagram

ISC_CFA_CTRL.ENABLE	CFA_DATA Slice	Value
0	cfa_data[35:24]	wb_data[11:0]
	cfa_data[23:12]	wb_data[11:0]
	cfa_data[11:0]	wb_data[11:0]
1	cfa_data[35:24]	R = spatial_filter_R(wb_data[11:0])
	cfa_data[23:12]	G = spatial_filter_G(wb_data[11:0])
	cfa_data[11:0]	B = spatial_filter_B(wb_data[11:0])

The filter kernel size is 5, and requires two additional lines to initialize the filter. When ISC_CFA_CFG.EITPOL is set, the missing information is interpolated from the nearest neighbor. If ISC_CFA_CFG.EITPOL is cleared, only valid pixels are used to initialize the filter kernel, but the output number of lines is less than the input number of lines. In that case, four lines are consumed to fill the kernel.

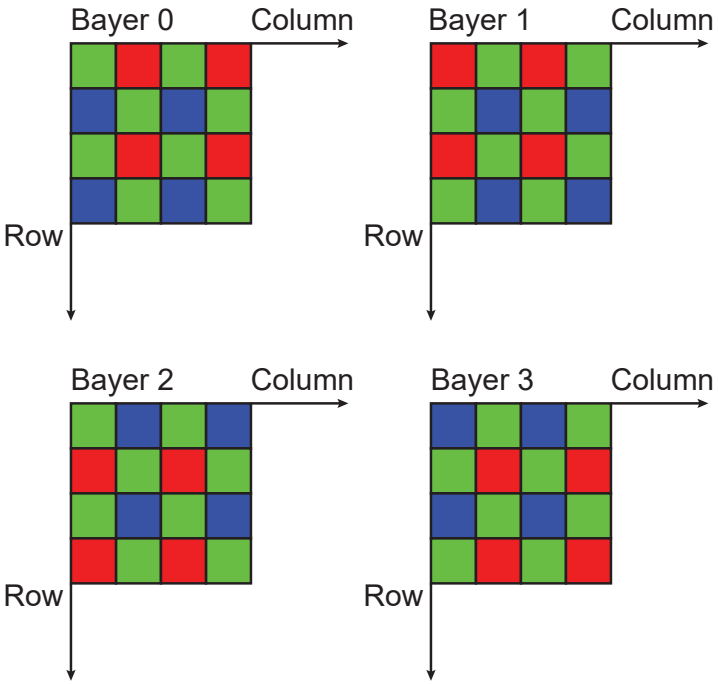
52.6.11.1. Frame Size Requirement when Edge Interpolation is Off, ISC_CFA_CFG.EITPOL Cleared

- Minimum number of rows (in): 5
- Minimum number of columns (in): 5

© 2026 Microchip Technology Inc. and its subsidiaries

- Number or rows after CFA: Number of rows (in) - 4
- Number of columns after CFA: Number of columns (in) - 4

52.6.11.2.Frame Size Requirement when Edge Interpolation is On, ISC_CFA_CFG.EITPOL Set



- Minimum number of rows (in): 3
- Minimum number of columns (in): 3
- Number of rows after CFA: Number of rows (in)
- Number of columns after CFA: Number of columns (in)

52.6.11.3.Bayer Mode and Edge Interpolation Description

When Edge Interpolation mode (ISC_CFA_CFG.EITPOL) is activated, dummy lines are generated using rows and columns replication.

The CFA module supports four sensor alignments using ISC_CFA_CFG.BAYCFG. See the figure below.

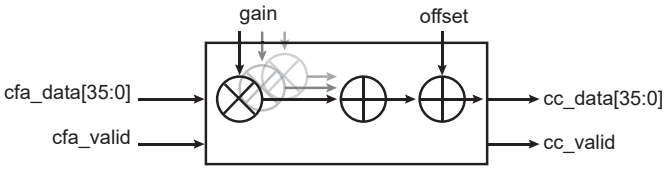


Figure 52.22. Supported Color Filter Array Patterns

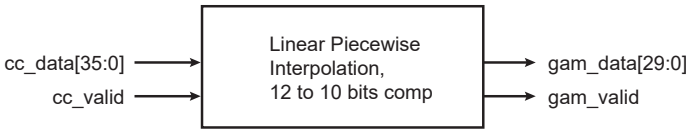
52.6.12. Color Correction (CC) Module

RGB color correction is used to compensate for cross color bleeding in the filter used with the image sensor. The module samples the cfa_data[35:0] 36-bit bus when cfa_valid is asserted and generate a cc_data[35:0] 36-bit wide bus and a cc_valid signal.

Figure 52.23. CC Block Diagram

There are three {gain, offset} sets for color component R, G, B.

© 2026 Microchip Technology Inc. and its subsidiaries



ISC_CC_CTRL.ENABLE	CC_DATA Slice	Value
0	cc_data[35:24]	cfa_data[11:0]
	cc_data[23:12]	cfa_data[11:0]
	cc_data[11:0]	cfa_data[11:0]
1	cc_data[35:24]	R=clipped(sum(cfa_data_x * gain_Rx) + offset_R)
	cc_data[23:12]	G=clipped(sum(cfa_data_x * gain_gx) + offset_g)
	cc_data[11:0]	B=clipped(sum(cfa_data_x * gain_Bx) + offset_B)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} \text{RRGAIN} & \text{RGGAIN} & \text{RBGAIN} \\ \text{GRGAIN} & \text{GGGAIN} & \text{GBGAIN} \\ \text{BRGAIN} & \text{BGGAIN} & \text{BBGAIN} \end{bmatrix} \times \begin{bmatrix} \text{cfa_data}[35:24] \\ \text{cfa_data}[23:12] \\ \text{cfa_data}[11:0] \end{bmatrix} + \begin{bmatrix} \text{ROFST} \\ \text{GOFST} \\ \text{BOFST} \end{bmatrix}$$

52.6.13. Gamma Curve (GAM) Module

The GAM module samples the cc_data[35:0] bus when cc_valid is asserted, and generates gam_data[29:0] 30-bit width data along with the validity signal gam_valid. Imaging devices have non-linear characteristics, but the transfer function is approximated by a power function. The intensity of each of the linear RGB components is transformed to a non-linear signal through the use of the gamma correction submodule. The power function is linearly interpolated using 64 breakpoints. This also performs a 12-bit to 10-bit compression. The polynomial for the linear interpolation between breakpoints is i and i +1. Consequently, for each breakpoint, two values are required: constant and slope. The table values are programmable through the user interface when the gamma correction module is disabled (ISC_GAM_CTRL.ENABLE is cleared). ISC_GAM_RENTRY is used for Red gamma correction. ISC_GAM_GENTRY is used for Green gamma correction. ISC_GAM_BENTRY is used for Blue gamma correction. Each table entry is composed of a 10-bit (signed) slope and a 10-bit constant.

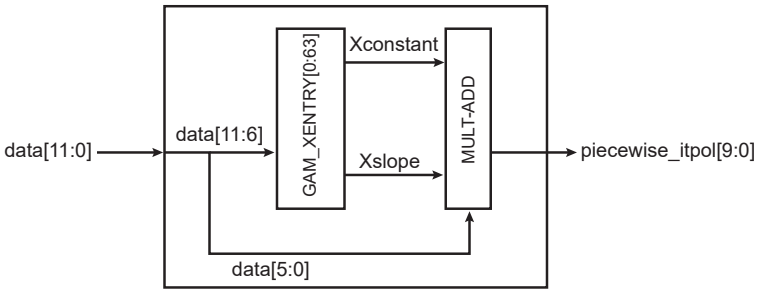


Figure 52.24. GAM Block Diagram

ISC_GAM_CTRL.ENABLE	ISC_GAM_CTRL.XLUT	GAM_DATA Slice	Value
0	0	gam_data[29:0]	cc_data[29:0]
1	0	gam_data[29:20]	cc_data[35:26]
		gam_data[19:10]	cc_data[23:14]
		gam_data[9:0]	cc_data[11:2]

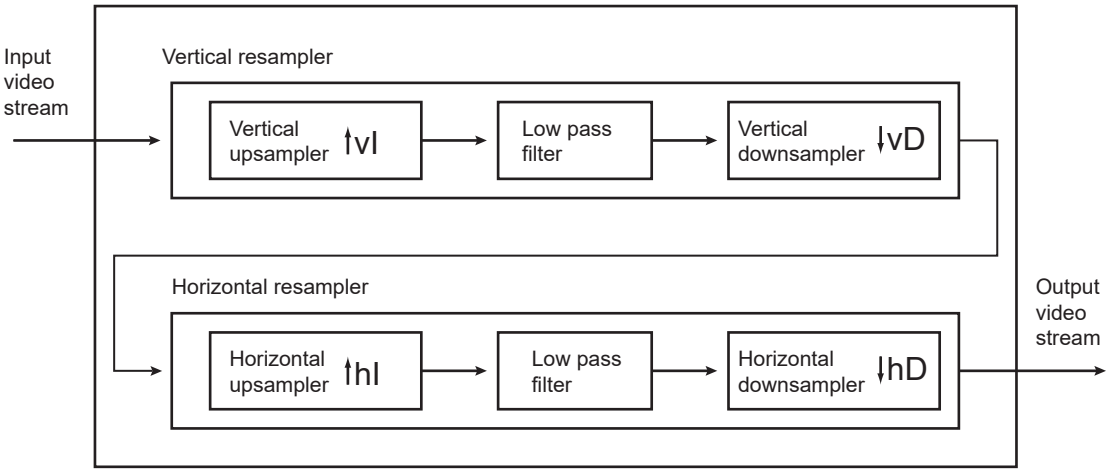
		gam_data[19:10]	G=piecewise_itpol(cc_data_r[23:12])
		gam_data[9:0]	B=piecewise_itpol(cc_data_r[11:0])

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 52.25. Piecewise Linear Interpolation Block Diagram

The interpolation consists of three tables that store the function values GAM_XENTRY[0:63] where X stands for R, G and B. The input of the table has six bits. It outputs a slope and a constant. The slope is later multiplied by the data lsb (6-bit) and added to a constant. The final value is the gamma-corrected value of the input. This module performs a 12-to-10 compression.



52.6.14. Scaler Function

The video pipeline includes a hardware scaler that allows an image resize in both the horizontal and the vertical directions. It integrates a two-tap or four-tap filter architecture with programmable polyphase coefficients or fixed bilinear interpolation coefficients.

52.6.14.1. Video Scaler Description

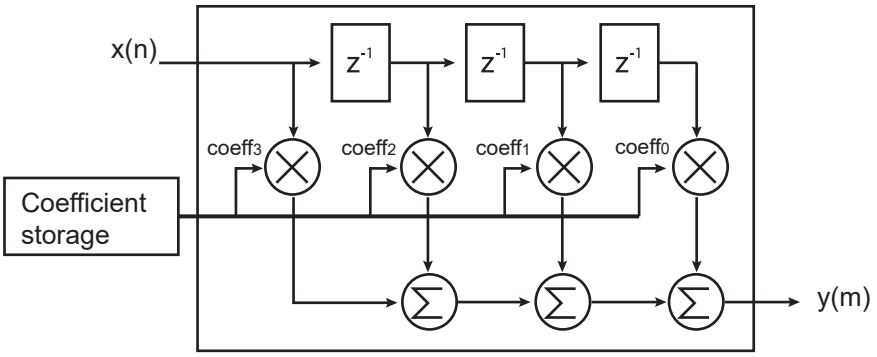
The scaling operation is based on a vertical and horizontal resampling algorithm. The sampling rate of the original image is increased when the video is upscaled, and decreased when the video is downscaled. The horizontal and vertical low pass filters are both designed to minimize the aliasing effect.

Figure 52.26. Video Resampler Architecture

The horizontal and vertical resamplers include a 16-phase 4-tap filter equivalent to a 64-tap FIR illustrated in the figures below.

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 52.27. Horizontal Resampler Filter Architecture



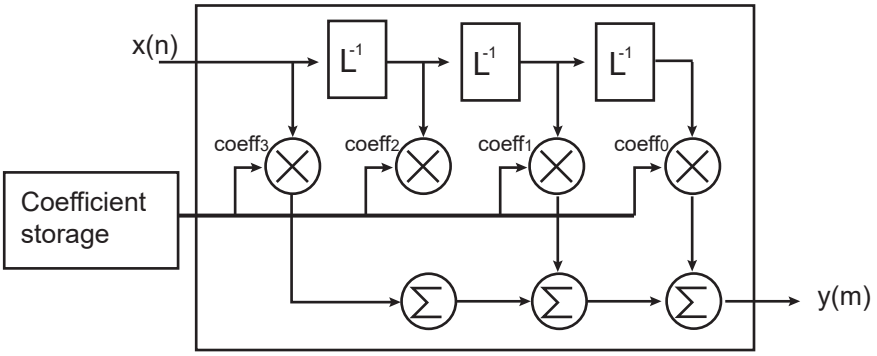


Figure 52.28. Vertical Resampler Filter Architecture

52.6.14.2.Horizontal Scaler Main Configuration

ISC_VHXS_SS.XS indicates the horizontal size minus one of the image in the system memory. ISC_VHXS_DS.XD contains the horizontal size minus one of the output image.

ISC_VHXS_CTRL.HXSEN is used to activate the horizontal scaler. The scaling factor is programmed in ISC_HXS_FACT.HFACT. The following equation calculates the horizontal scaling factor (HFACT) value:

$$\mathrm{HFACT} = \mathrm{round}\left(\frac{2^{20} \times \mathrm{IMAGE_X_SIZE_IN}}{\mathrm{IMAGE_X_SIZE_OUT}}\right)$$

The value HFACT is 24 bits wide (4-bit integer part, 20-bit fractional part), hence the horizontal downsampling capacity is limited to 16.0.

52.6.14.3.Vertical Scaler

ISC_VHXS_SS.YS indicates the vertical size minus one of the image in the system memory. ISC_VHXS_DS.YD contains the vertical size minus one of the output image.

ISC_VHXS_CTRL.VXSEN is used to activate the vertical scaler. The scaling factor is programmed in ISC_VXS_FACT.VFACT. The following equation calculates the vertical scaling factor (VFACT) value:

$$\mathrm{VFACT} = \mathrm{round}\left(\frac{2^{20} \times \mathrm{IMAGE_Y_SIZE_IN}}{\mathrm{IMAGE_Y_SIZE_OUT}}\right)$$

The value VFACT is 24 bits wide (4-bit integer part, 20-bit fractional part), hence the vertical downsampling capacity is limited to 16.0.

52.6.14.4.Input/Output Pixel Alignment

Depending on application requirements, output pixel alignment according to input pixels can be tuned for the horizontal and vertical scaler. This tuning modifies the position of the output image within the range of the filter length. Two different types of configuration fields are used, Filter Taps

© 2026 Microchip Technology Inc. and its subsidiaries

Shift and Filter Init Phase Offset. Each of them produces a filter spatial response shift as described below.

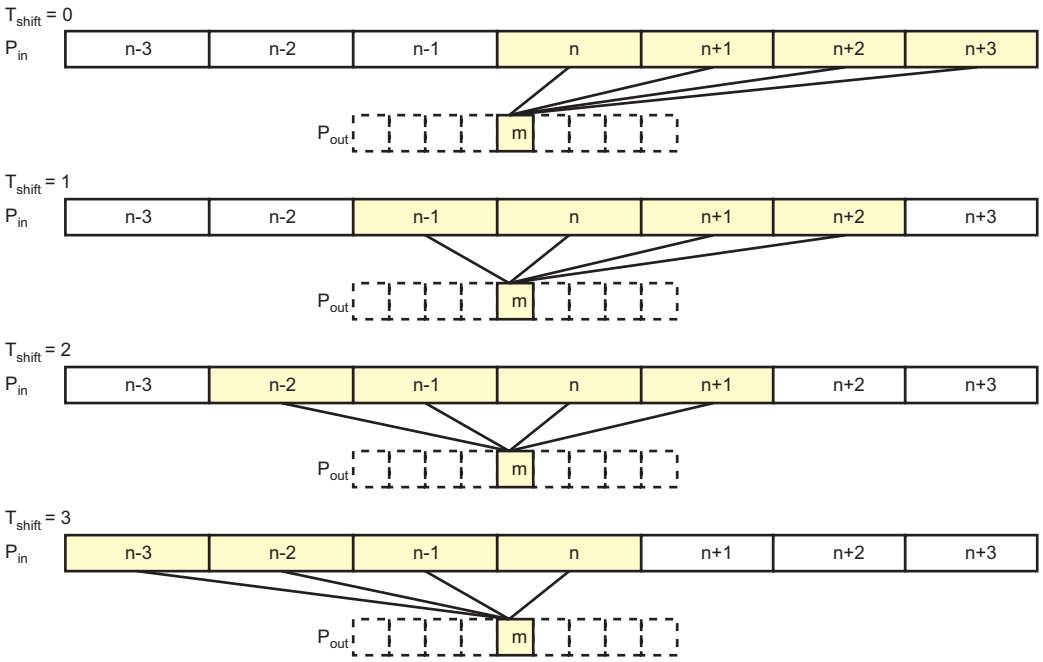
Filter taps shift (T_{shift}) determines which set of input pixels is used at filter input to process a given output pixel. The following equation shows how the output pixel is calculated through the filter:

$$Pout\left(m\right) = \sum_{k=0}^{N-1} P_{in}\left(n + N - 1 - k - T_{shift}\right) \times h(k,p)$$

With :

P_{in}—input pixel component value (any R, G or B in RGB)

N—the filter number of taps (N=SCALER_FILT_NUM_PHASES)



T_{shift}—Filter taps shift

h(k,p)—Filter taps value depending on tap number k, and phase index p

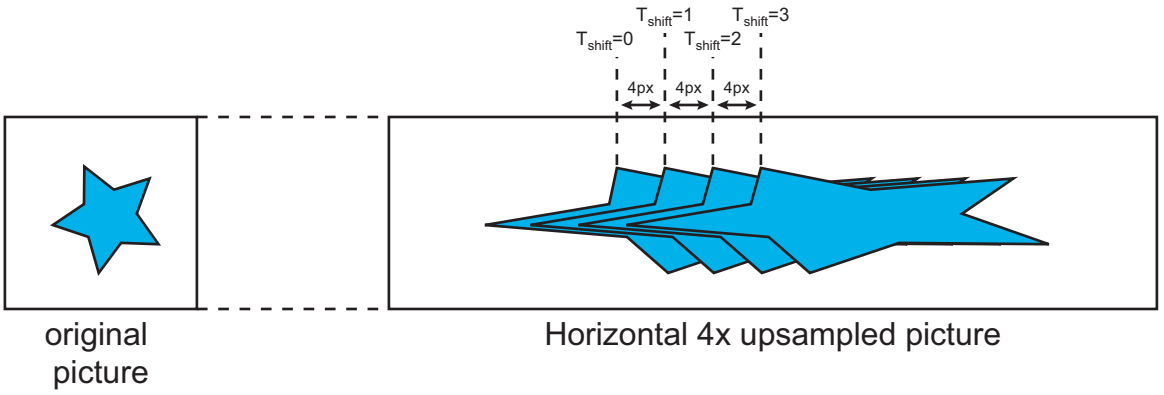
P_{out}—output pixel component value (R, G or B in RGB mode)

The output image is shifted by the value T_{shift}/FACT, with FACT=HFACT for horizontal scaling and FACT=VFACT for vertical scaling. The following figures illustrate a use case of upsampling by 4 (VFACT=0.25x220):

Figure 52.29. Filter Taps Shift

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 52.30. Filter Taps Shift Results for Different Horizontal T_{shift} Values (Upsampling by 4)



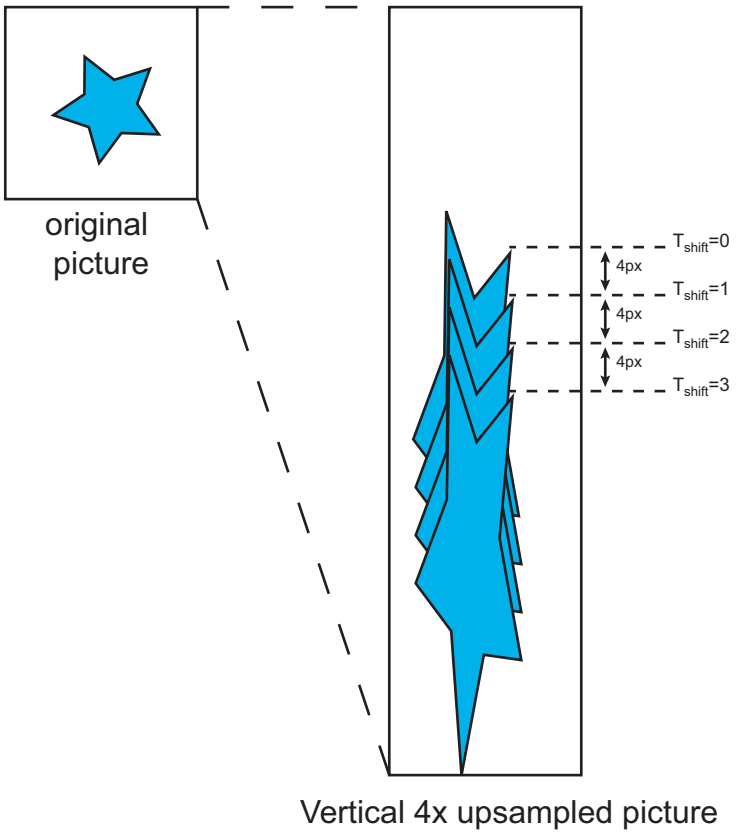


Figure 52.31. Filter Taps Shift Results for Different Vertical T_{shift} Values (Upsampling by 4)

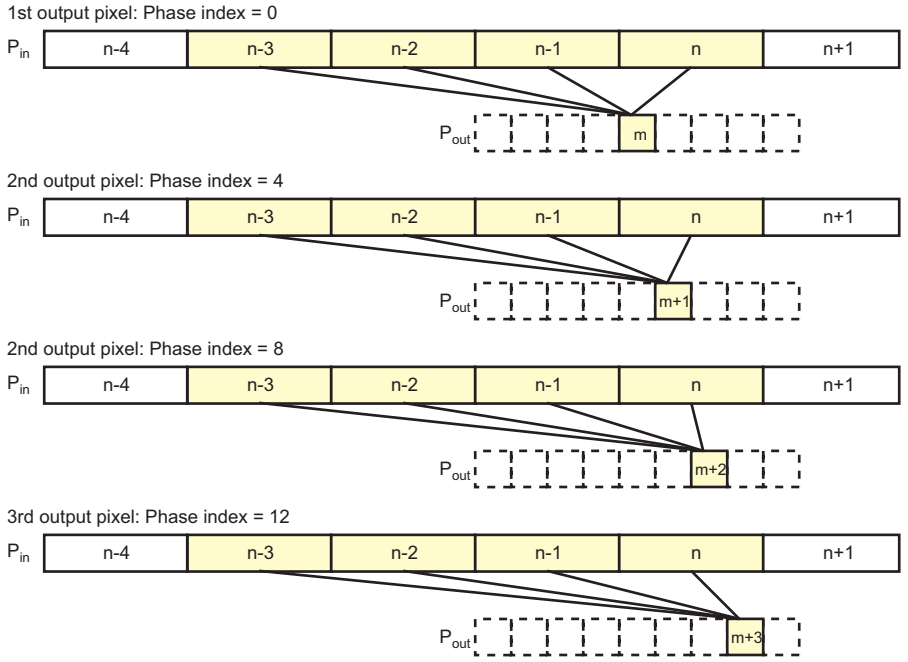
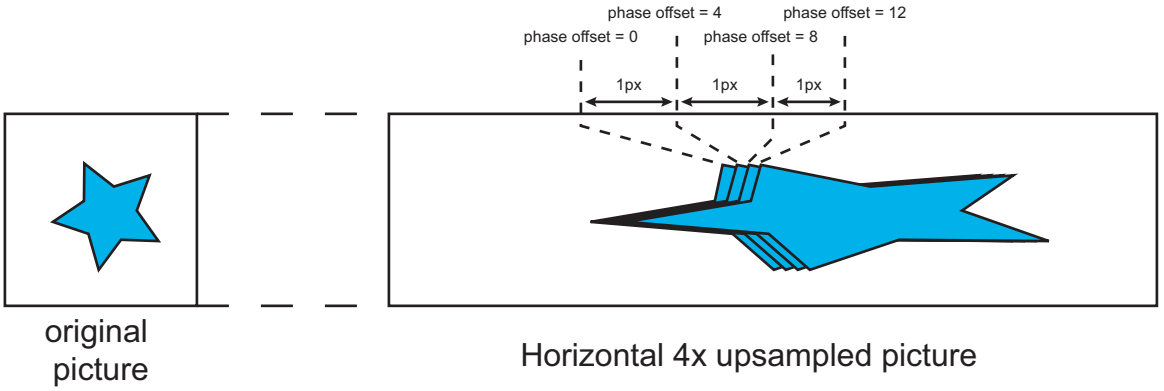


Filter taps shift (T_{shift}) is controlled by ISC_HXS_CFG.FILTCFG for the horizontal scaler, and ISC_VXS_CFG.FILTCFG for the vertical scaler.

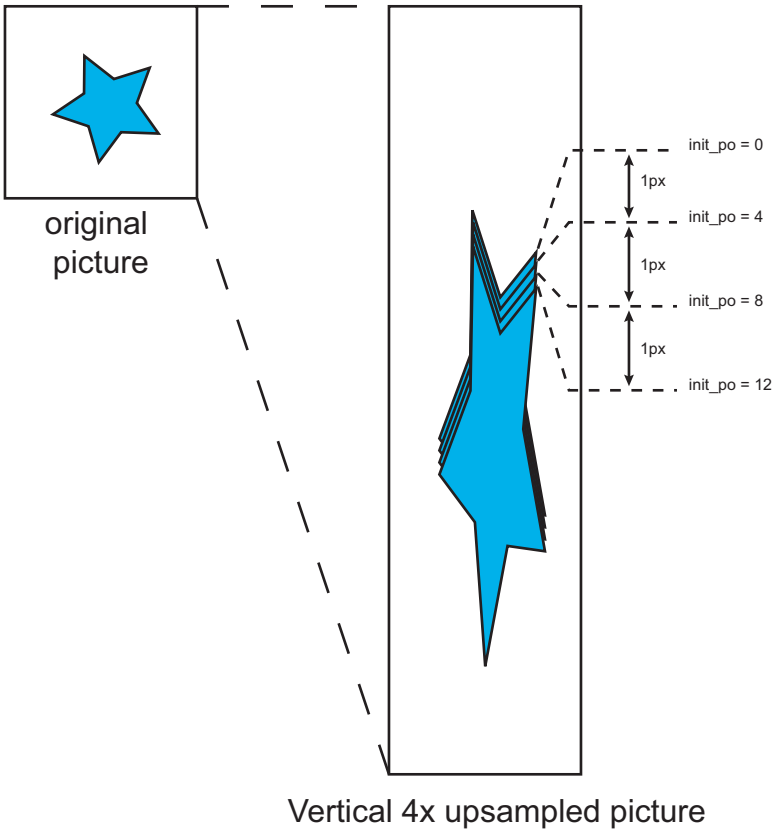
During the resampling process, a filter tap phase is selected for each output pixel, representing the fractional part of the output pixel spatial position, according to the input pixel width. An input pixel width is subsampled in values of 16 phases, each phase p corresponding to a subset of filter taps. Phase 0 corresponds to 0 fractional shift. Incrementing the phase index by 1 corresponds to a spatial shift of 1/16 pixel width.

The following figures illustrate a use case of upsampling by 4 (four output pixels for one input pixel), with a fixed T_{shift} value.



© 2026 Microchip Technology Inc. and its subsidiaries

Figure 52.32. Filter Phase Index (T_{shift} = 3)

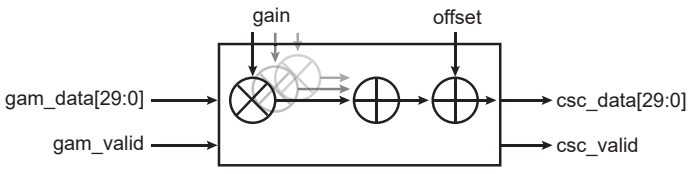


A phase offset adds a fractional shift to all pixels of the frame. This is illustrated in the figures below for the use case when upsizing by 4.

Figure 52.33. Horizontal Initial Phase Offset On Upsizing by 4

© 2026 Microchip Technology Inc. and its subsidiaries

Figure 52.34. Vertical Initial Phase Offset on Upsizing by 4



The initial phase offset is controlled by ISC_HXS_CFG.OFFSET for the horizontal scaler, and ISC_VXS_CFG.OFFSET for the vertical scaler.

52.6.15. Color Space Conversion (CSC) Module

By converting an image from RGB to YCbCr color space, it is possible to separate Y, Cb and Cr information. The CSC samples the gam_data[29:0] 30-bit data bus, extracts YCbCr information from the sampled data, and then generates the color-converted data csc_data[29:0] and the validity signal csc_valid.

Figure 52.35. CSC Block Diagram

ISC_CSC_CTRL.ENABLE	CSC_DATA Slice	Value
0	csc_data[29:0]	gam_data[29:0]
1	csc_data[29:20]	Y = clipped(sum(gam_data_x * gain_Yx) + offset_y << 2)
	csc_data[19:10]	Cb = clipped(sum(gam_data_x * gain_Cbx)+offset_cb << 2)
	csc_data[9:0]	Cr = clipped(sum(gam_data_x * gain_Crx)+offset_cr << 2)

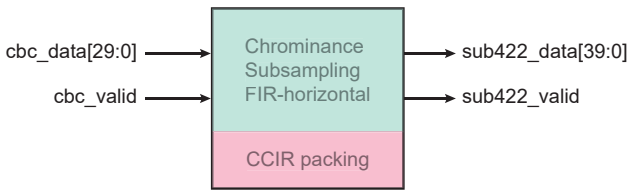
$$\begin{bmatrix} Y \\ CB \\ CR \end{bmatrix} = \begin{bmatrix} YR & YG & YB \\ CBR & CBG & CBB \\ CRR & CRG & CRB \end{bmatrix} \times \begin{bmatrix} gam_data[29:20] \\ gam_data[19:10] \\ gam_data[9:0] \end{bmatrix} + \begin{bmatrix} YOFST \\ CBOFST \\ CROFST \end{bmatrix}$$

52.6.16. Contrast, Brightness, Hue and Saturation

This module is for YUV formatting purposes. Brightness offset allows the Luminance to be adjusted. Hue is used for Chroma phase adjustment, and Color Saturation for Chroma amplitude. Contrast gain is applied on all pixel components (Luma and Chroma). The CBHS samples the csc_data[29:0] 30-bit bus when csc_valid is asserted and generates cbhs_data[29:0] with the validity signal cbc_valid.

Figure 52.36. CBHS Block Diagram



ISC_CBC_CTRL.ENABLE	ISC_CBC_CFG.CCIR	CBC_DATA Slice	Value
0	0	cbc_data[29:0]	csc_data[29:0]

		cbc_data[9:0]	ccir656 stream with luminance correction

52.6.17. 4:4:4 To 4:2:2 Chrominance Horizontal Subsampler (SUB422) Module

The color space conversion output stream is a full-bandwidth YCbCr 4:4:4 signal. The chrominance subsampling divides the horizontal chrominance sampling rate by two. A horizontal low pass filter is applied to avoid aliasing effect. The SUB422 module samples 444 full scale YCbCr cbc_data[29:0] 30-bit data, performs horizontal subsampling and generates the sub422_data[39:0] 40-bit data bus with its validity signal sub422_valid.

Figure 52.37. SUB422 Block Diagram

© 2026 Microchip Technology Inc. and its subsidiaries

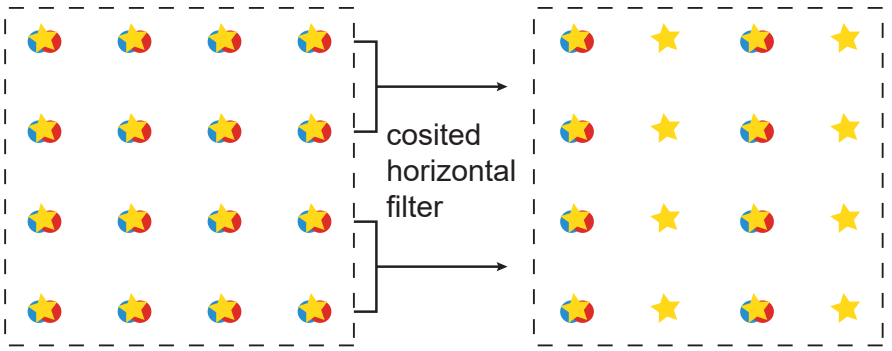
ISC_SUB422_CTRL.ENABLE	ISC_SUB422_CFG.CCIR	SUB422_DATA Slice	Value
0	0	sub422_data[29:0]	cbc_data[29:0]
1	0	sub422_data[39:30]	Y1= cbc_data1[29:20]
		sub422_data[29:20]	Y0 = cbc_data0[29:20]
		sub422_data[19:10]	Cb = filter_hor(cbc_data[19:10])
		sub422_data[9:0]	Cr = filter_hor(cbc_data[9:0])
1	1	sub422_data[39:30]	Y1 = cbc_data[9:0]
		sub422_data[29:20]	Y0 = cbc_data[9:0]
		sub422_data[19:10]	Cb = cbc_data[9:0]
		sub422_data[9:0]	Cr = cbc_data[9:0]

The filter_hor function included in the sub422 module is the chrominance horizontal filter.

sub422 Data Slice	YCbCr Mapping
sub422_data[39:30]	Y1 (sample n)
sub422_data[29:20]	Y0 (sample n-1)
sub422_data[19:10]	Cb (from filter)
sub422_data[9:0]	Cr (from filter)

The filter chrominance position is selectable through the use of ISC_SUB422_CFG.FILTER.

Figure 52.38. Cosited Filter Configuration



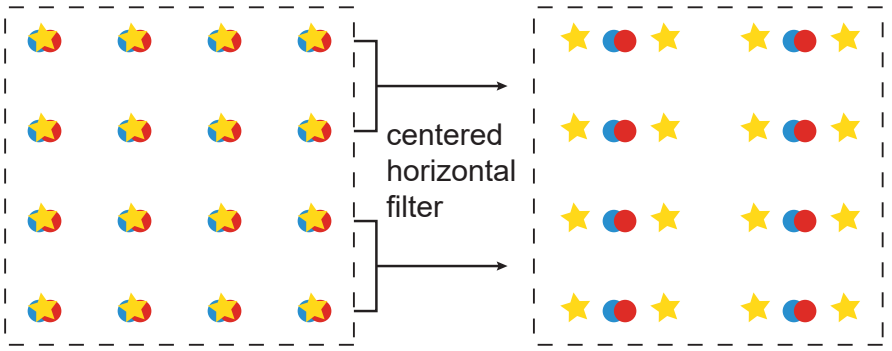


Figure 52.39. Centered Filter Configuration

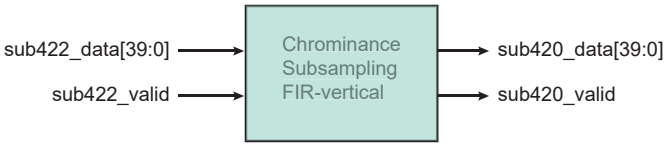
The SUB422 module performs luminance and chrominance packing. When the line length is odd, the missing luminance is a copy of the last but one luminance. It also means that the final dma stream written to memory is equal to the original horizontal size plus one when the line length is odd.

SUB422_DATA Slice	Even Line Length	Odd Line Length
sub422_data[39:30]	Y(n)	Y(n-1)



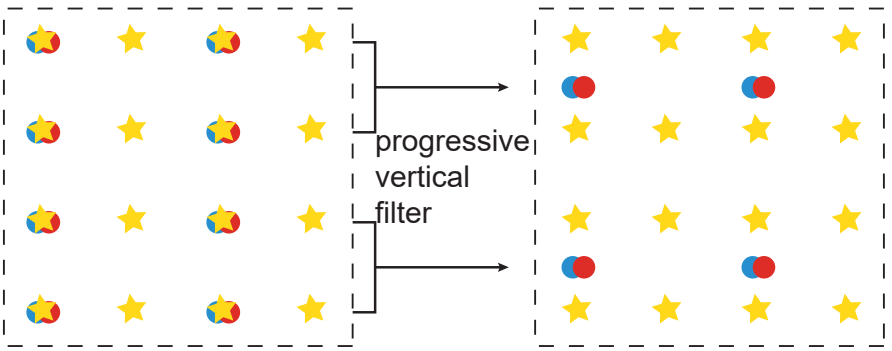
© 2026 Microchip Technology Inc. and its subsidiaries

4:4:4 To 4:2:2 Chrominance Horizontal Subsampler (SUB422) Module (continued)		
SUB422_DATA Slice	Even Line Length	Odd Line Length
sub422_data[29:20]	Y(n-1)	Y(n-1)
sub422_data[19:10]	Cb (filtered)	Cb (filtered)
sub422_data[9:0]	Cr (filtered)	Cr (filtered)

52.6.18. 4:2:2 To 4:2:0 Chrominance Vertical Subsampler (SUB420) Module

The chrominance subsampling divides the vertical chrominance sampling rate by two. A vertical low pass filter is applied to avoid aliasing effect. Two different filters are used when the source frame is interlaced, and the filter configuration depends on the field value (the field is propagated in the video pipeline).

Figure 52.40. SUB420 Block Diagram



The SUB420 module samples the sub422_data[39:0] 40-bit data when sub422_valid is asserted, then it performs a vertical subsampling and generates a valid sub420_data[39:0] 40-bit word and the corresponding sub420_valid signal.

ISC_CFA_CTRL.ENABLE	SUB420_DATA Slice	Value
0	sub420_data[39:0]	sub422_data[39:0]
1	sub420_data[39:30]	Y1 = sub422_data[39:30]
	sub420_data[29:20]	Y0 = sub422_data[29:20]
	sub420_data[19:10]	Cb = filter_ver(sub422[19:10])
	sub420_data[9:0]	Cr = filter_ver(sub422[9:0])

The vertical filter is a two-tap filter; for progressive content the coefficient i {1, 1}. When an interlaced field is downsampled, the coefficients are different between the top and the bottom fields.

Figure 52.41. Vertical Chrominance Filter for Progressive Content (Cosited Chrominance Example)

SUB420 Input Number of Rows	SUB420 Luminance Rows	SUB420 Chrominance Rows
M rows, M odd	M rows	(M+1)/2 rows
M rows, M even	M rows	M/2 rows

52.6.19. Rounding, Limiting and Packing (RLP) Module

This module is used to round, limit and pack in the incoming pixel stream before the host DMA module. The RLP samples the sub420_data[39:0] 40-bit data bus and generates rlp_data[31:0] 32-bit data words with the associated validity signal rlp_valid.

Figure 52.43. RLP Block Diagram

	rlp_data[23:16]	R = sub420_data[29:22]
	rlp_data[15:8]	G = sub420_data[19:12]
	rlp_data[7:0]	B = sub420_data[9:2]
YCbCr422, YCbCr420	rlp_data[31:24]	Y1 = round(sub420_data[39:32])
	rlp_data[23:16]	Y0 = round(sub420_data[29:22])
	rlp_data[15:8]	Cb = round(sub420_data[19:12])
	rlp_data[7:0]	Cr = round(sub420_data[9:2])
YCbCr422, YCbCr420	rlp_data[31:24]	Y1 = round_limit(sub420_data[39:32])
	rlp_data[23:16]	Y0 = round_limit(sub420_data[29,22])
	rlp_data[15:8]	Cb = round_limit(sub420_data[19,12])
	rlp_data[7:0]	Cr = round_limit(sub420_data[9:2])
Undefined	rlp_data[31:0]	sub420_data[31:0]

The round_limit function provides a simple method to round and limit the range of both Luminance and Chrominance signals.

ISC_RLP_CFG	8-bit Full Range	8-bit Limited Range
Y	0–255	16–235
Cb	0–255	16–240
Cr	0–255	16–240

52.6.20. DMA Interface

The descriptor-based DMA interface supports multiple buffers. A DMA stride value shows the offset between two consecutive lines (in bytes). If the stride is set to zero, the frame buffer is contiguous.

When ISC_DCTRL.WB is set (Write Back), the DMA interface performs a single write operation to ISC_DCTRL, and sets ISC_DCTRL.DONE to one and ISC_DCTRL.FIELD to the value of the frame field when interlaced content is being used. This means that interlaced fields are tagged with their relevant field values. The Write Back operation is always performed when the whole frame has been transferred to memory.

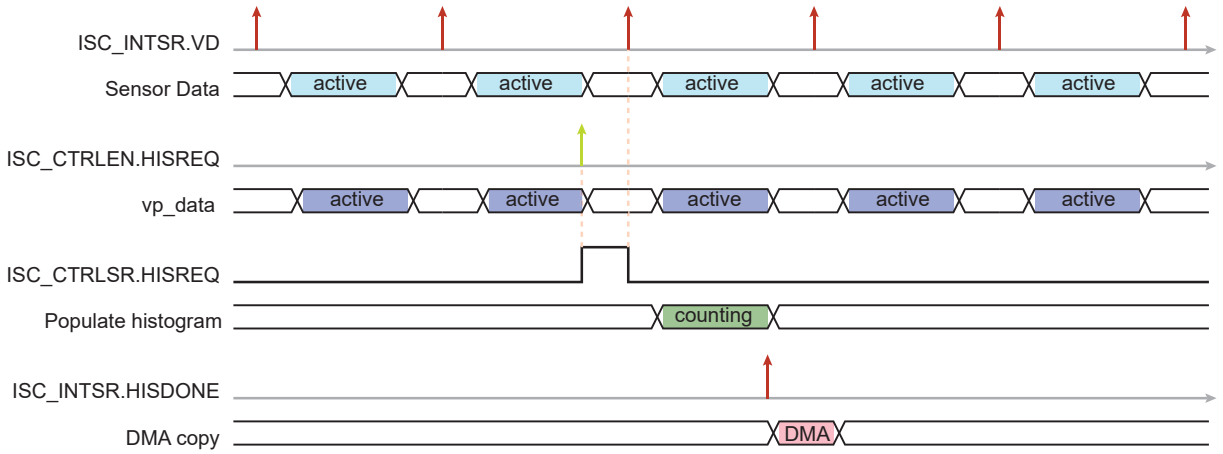
52.6.21. Histogram Module



For each possible pixel value, the histogram counts the number of times the value was encountered in the current image. RGGB Bayer, raw data or luminance histogram are available. There are 512 entries in the histogram entries, and each histogram bin can count up to 2^{20} data. As the table entries are limited, each bin is actually a range, i.e., least significant bits are ignored. A write to ISC_CTRLEN.HISREQ initiates a new histogram. The counting operation ends when ISC_INTSR.HISDONE is set. At that time, a software or hardware DMA transfer copies the table from the interface to the internal or external memory. To clear the table content (for a new operation), use ISC_CTRLEN.HISCLR. An automatic clear (reset after read) is available when ISC_HIS_CFG.RAR is set. In that case, as soon as the data is read from the table, the table entry is cleared.

Figure 52.46. Histogram Request Timing Diagram

52.6.22. Register Write Protection

To prevent any single software error from corrupting ISC behavior, certain registers in the address space can be write-protected by setting the bits WPCFGEN, WPITEN, WPCREN in ISC_WPMR.

If a write access to a write-protected register is detected, the Write Protection Violation Status (WPVS) flag in ISC_WPSR is set and the Write Protection Violation Source (WPVSRC) field indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading ISC_WPSR.

52.7.1. ISC Control Enable Register

Name: ISC_CTRLEN
Offset: 0x00
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:
0: No effect.

1: Enables the corresponding command.

This register can only be written if WPCREN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access							W

Bit	7	6	5	4	3	2	1	0
Access					W	W	W	W
Reset					–	–	–	–

Bit 9 – FUPPRO Force Update Color Profile

Bit 3 – HISCLR Histogram Clear

Bit 2 – HISREQ Histogram Request

Bit 1 – UPPRO Update Profile

Bit 0 – CAPTURE Capture Input Stream Command

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.2. ISC Control Disable Register

Name: ISC_CTRLDIS
Offset: 0x04
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:
0: No effect.

1: Performs the corresponding command.

This register can only be written if WPCREN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

52.7.3. ISC Control Status Register

Name: ISC_CTRLSR
Offset: 0x08
Reset: 0x00000000
Property: Read-only

Bit	31	30	29	28	27	26	25	24
	SIP							
Access	R							
Reset	0							

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
				FIELD		HISREQ	UPPRO	CAPTURE
Access				R		R	R	R
Reset				0		0	0	0

Bit 31 – SIP Synchronization In Progress

Value	Description
0	The double domain synchronization is terminated.
1	The double domain synchronization is in progress.

Bit 4 – FIELD Field Status (only relevant when the video stream is interlaced)

Value	Description
0	The current field/segment is a top field
1	The current field/segment is a bottom field.

Bit 2 – HISREQ Histogram Request Pending

Value	Description
0	There is no histogram pending request.
1	Indicates that the histogram request is still pending.

Bit 1 – UPPRO Profile Update Pending

Value	Description
0	There is no profile update pending request.
1	Indicates that the profile update request is still pending.

Bit 0 – CAPTURE Capture Pending

Value	Description
0	Capture mode is disabled.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	Capture is pending.

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.4. ISC Parallel Front End Configuration 0 Register

Name: ISC_PFE_CFG0
Offset: 0x0C
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGEN is cleared in ISC_WPMR.

	CONT	MODE[2:0]			FPOL	PPOL	VPOL	HPOL
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit 31 – REP Up Multiply with Replication

Value	Description
0	Unused bits are stuck at 0.
1	Unused bits are copied from MSB.

Bits 30:28 – BPS[2:0] Bits Per Sample

Value	Name	Description
0	TWELVE	12-bit input
1	ELEVEN	11-bit input
2	TEN	10-bit input
3	NINE	9-bit input
4	EIGHT	8-bit input
5	FORTY	40-bit input (used for MIPI formats up to forty bits per pixel)

Bit 27 – CCIR_REP CCIR Replication

Value	Description
0	Unused bits are stuck at 0.
1	Unused bits are copied from MSB.

Bits 23:16 – SKIPCNT[7:0] Frame Skipping Counter

Bit 14 – MIPI MIPI Interface Connection

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	Input data come from the physical parallel interface.
1	Input data come from the physical MIPI interface.

Bit 13 – ROWEN Row Cropping Enable

Value	Description
0	Row Cropping is disabled.
1	Row Cropping is enabled.

Bit 12 – COLEN Column Cropping Enable

Value	Description
0	Column Cropping is disabled.
1	Column Cropping is enabled.

Bit 11 – CCIR10_8N CCIR 10 bits or 8 bits

Value	Description
0	8-bit mode.
1	10-bit mode.

Bit 10 – CCIR_CRC CCIR656 CRC Decoder

Value	Description
0	Embedded CRC is discarded.
1	Embedded CRC is decoded.

Bit 9 – CCIR656 CCIR656 input mode

Value	Description
0	HSYNC and VSYNC signals are used to synchronize the input stream.
1	Embedded synchronization is used.

Bit 8 – GATED Gated input clock

Value	Description
0	The external pixel clock is free running.
1	The external pixel clock is gated.

Bit 7 – CONT Continuous Acquisition

Value	Description
0	Single Shot mode.
1	Video mode.

Bits 6:4 – MODE[2:0] Parallel Front End Mode

Value	Name	Description
0	PROGRESSIVE	Video source is progressive.
1	DF_TOP	Video source is interlaced, two fields are captured starting with top field.
2	DF_BOTTOM	Video source is interlaced, two fields are captured starting with bottom field.
3	DF_IMMEDIATE	Video source is interlaced, two fields are captured immediately.
4	SF_TOP	Video source is interlaced, one field is captured starting with the top field.
5	SF_BOTTOM	Video source is interlaced, one field is captured starting with the bottom field.
6	SF_IMMEDIATE	Video source is interlaced, one field is captured starting immediately.

Bit 3 – FPOL Field Polarity

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	Top field is sampled when F value is 0; Bottom field is sampled when F value is 1.
1	Top field is sampled when F value is 1; Bottom field is sampled when F value is 0.

Bit 2 – PPOL Pixel Clock Polarity

Value	Description
0	The pixel stream is sampled on the rising edge of the pixel clock.
1	The pixel stream is sampled on the falling edge of the pixel clock.

Bit 1 – VPOL Vertical Synchronization Polarity

Value	Description
0	VSYNC signal is active high, i.e. valid pixels are sampled when VSYNC is asserted.
1	VSYNC signal is active low, i.e. valid pixels are sampled when VSYNC is deasserted.

Bit 0 – HPOL Horizontal Synchronization Polarity

Value	Description
0	HSYNC signal is active high, i.e. valid pixels are sampled when HSYNC is asserted.
1	HSYNC signal is active low, i.e. valid pixels are sampled when HSYNC is deasserted.

52.7.5. ISC Parallel Front End Configuration 1 Register

Name: ISC_PFE_CFG1
Offset: 0x10
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGEN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
	COLMAX[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	COLMAX[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	COLMIN[15:8]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	COLMIN[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 31:16 – COLMAX[15:0] Column Maximum Limit
Horizontal ending position of the cropping area.

Bits 15:0 – COLMIN[15:0] Column Minimum Limit
Horizontal starting position of the cropping area.

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							MCEN	ICEN
Access							W	W
Reset							–	–

Bit 1 – MCEN Camera Sensor Clock Domain Enable

Value	Description
0	No effect.
1	Enables the camera sensor clock.

Bit 0 – ICEN ISP Clock Enable

Value	Description
0	No effect.
1	Enables the ISP clock.

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.8. ISC Clock Disable Register

Name: ISC_CLKDIS
Offset: 0x1C
Reset: –
Property: Write-only

The following configuration values are valid for all listed bit names of this register:
0: No effect.

1: Performs the corresponding command.

This register can only be written if WPCREN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
							MCSR	ICSR
Access							R	R
Reset							0	1

Bit 31 – SIP Synchronization In Progress

Value	Description
0	The double domain synchronization operation is over.
1	The double domain synchronization operation is in progress.

Bit 1 – MCSR Camera Sensor Clock Status Register

Value	Description
0	The camera sensor clock is disabled.
1	The camera sensor clock is enabled.

Bit 0 – ICSR ISP Clock Status Register

Value	Description
0	The ISP clock is disabled.
1	The ISP clock is enabled.

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.10. ISC Clock Configuration Register

Name: ISC_CLKCFG
Offset: 0x24
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGEN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16

Reset			0	0			0	0

Bit	7	6	5	4	3	2	1	0
			DIS	SWRST			HD	VD
Access			R	R			R	R
Reset			0	0			0	0

Bit 29 – GFOV FIFO Overflow Interrupt (relevant if MIPI interface is not selected) (cleared on read)

Value	Description
0	No FIFO overflow detected since the last read of the Interrupt Status register.
1	A FIFO overflow has been detected.

Bit 28 – CCIRERR CCIR Decoder Error Interrupt (cleared on read)

Value	Description
0	No CCIR CRC error detected since the last read of the Interrupt Status register.
1	A CCIR CRC error has been detected.

Bit 27 – HDTO Horizontal Synchronization Timeout Interrupt (cleared on read)

Value	Description
0	A horizontal synchronization is detected.
1	No horizontal synchronization is detected.

Bit 26 – VDTO Vertical Synchronization Timeout Interrupt (cleared on read)

Value	Description
0	A vertical synchronization is detected.
1	No vertical synchronization is detected.

Bit 25 – DAOV Data Overflow Interrupt (cleared on read)

Value	Description
0	No data overflow error occurred since the last reset of the Interrupt Status register.

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
1	A data overflow occurred.

Bit 24 – VFPOV Vertical Front Porch Overflow Interrupt (cleared on read)

Value	Description
0	No vertical front porch error occurred since the last read of the Interrupt Status register.
1	The vertical synchronization has been detected but the DMA channel is still busy.

Bit 20 – RERR Read Channel Error Interrupt (cleared on read)

Value	Description
0	No read channel error since the last read of the Interrupt Status register.
1	A read channel error occurred when the ISC read the descriptor.

Bits 18:17 – WERRID[1:0] Write Channel Error Identifier (cleared on read)

Value	Name	Description
0	CH0	An error occurred for Channel 0 (RAW/RGB/Y)
1	CH1	An error occurred for Channel 1 (CbCr/Cb)
2	CH2	An error occurred for Channel 2 (Cr)
3	WB	Write back channel error

Bit 16 – WERR Write Channel Error Interrupt (cleared on read)

Value	Description
0	No write channel error since the last read of the Interrupt Status register.
1	A write channel error occurred.

Bit 13 – HISCLR Histogram Clear Interrupt (cleared on read)

Value	Description
0	No Histogram Clear Interrupt has been raised since the last read of the Interrupt Status register.
1	The Histogram Clear Interrupt has occurred.

Bit 12 – HISDONE Histogram Completed Interrupt (cleared on read)

Value	Description
0	No Histogram Completed Interrupt has been raised since the last read of the Interrupt Status register.
1	The Histogram Completed Interrupt has occurred.

Bit 9 – LDONE DMA List Done Interrupt (cleared on read)

Value	Description
0	No DMA List Done interrupt has occurred since the last read of the Interrupt Status register.
1	The DMA List Done interrupt has occurred.

Bit 8 – DDONE DMA Done Interrupt (cleared on read)

Value	Description
0	No DMA Transfer Done interrupt has occurred since the last read of the Interrupt Status register.
1	The DMA Transfer Done interrupt has occurred.

Bit 5 – DIS Disable Completed Interrupt (cleared on read)

Value	Description
0	The disable has not occurred since the last read of the Interrupt Status register.
1	The disable has completed.

© 2026 Microchip Technology Inc. and its subsidiaries

Bit 4 – SWRST Software Reset Completed Interrupt (cleared on read)

Value	Description
0	No software reset completion since the last read of the Interrupt Status register.
1	The software reset has completed.

Bit 1 – HD Horizontal Synchronization Detected Interrupt (cleared on read)

Value	Description
0	No horizontal synchronization detection since the last read of the Interrupt Status register.
1	A horizontal synchronization has been detected.

Bit 0 – VD Vertical Synchronization Detected Interrupt (cleared on read)

Value	Description
0	No vertical synchronization detection since the last read of the Interrupt Status register.
1	A vertical synchronization has been detected.

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.15. ISC Defective Pixel Control Register

Name: ISC_DPC_CTRL
Offset: 0x40
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCREN is cleared in ISC_WPMR.

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
						BLCEN	GDCEN	DPCEN
Access						R/W	R/W	R/W
Reset						0	0	0

Bit 2 – BLCEN Black Level Correction Enable

Value	Description
0	Black level correction is disabled.
1	Black level correction is enabled.

Bit 1 – GDCEN Green Disparity Correction Enable

Value	Description
0	Green disparity correction is disabled.
1	Green disparity correction is enabled.

Bit 0 – DPCEN Defective Pixel Correction Enable

Value	Description
0	Defective pixel correction is disabled.
1	Defective pixel correction is enabled.

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.16. ISC Defective Pixel Configuration Register

Name: ISC_DPC_CFG
Offset: 0x44
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGEN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
	BLOFST[8:1]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16

Access		R/W	R/W	R/W				
Reset		0	0	0				

Bit	7	6	5	4	3	2	1	0
				EITPOL			BAYCFG[1:0]	
Access				R/W			R/W	R/W
Reset				0			0	0

Bits 31:23 – BLOFST[8:0] Black Level Offset Value
BLOFST is the default constant value subtracted from the incoming stream. The value is unsigned, 0:8:0 value.

Bits 22:20 – GDCCLP[2:0] Green Disparity Clipping Value
Green Disparity Clipping is performed between [$-2^{GDCCLP+1}$, $-2^{GDCCLP+1}-1$]

Bit 17 – RE_MODE Replacement Algorithm

Value	Description
0	Median pixel is used.
1	Average pixel is used.

Bit 16 – ND_MODE Noise Detection Mode

Value	Description
0	At least one detector flag is necessary to trigger the correction.
1	All detector flags are required to trigger the correction.

Bit 14 – TA_ENABLE Average Threshold Enable

Value	Description
0	Average detector is disabled.
1	Average detector is enabled.

Bit 13 – TC_ENABLE Closest Pixels Threshold Enable

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	Closest Pixels detector is disabled.
1	Closest Pixels detector is enabled.

Bit 12 – TM_ENABLE Median Threshold Enable

Value	Description
0	Median detector is disabled.
1	Median detector is enabled.

Bit 4 – EITPOL Edge Interpolation

Value	Description
0	No edge interpolation is performed.
1	Edge interpolation is performed.

Bits 1:0 – BAYCFG[1:0] Color Filter Array Pattern

Value	Name	Description
0	GRGR	Starting row configuration is G R G R (red row)
1	RGRG	Starting row configuration is R G R G (red row)
2	GBGB	Starting row configuration is G B G B (blue row)
3	BGBG	Starting row configuration is B G B G (blue row)

52.7.21. ISC White Balance Control Register

Name: ISC_WB_CTRL
Offset: 0x58
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCREN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
Access								R/W
Reset								0

Bit 0 – ENABLE White Balance Enable

Value	Description
0	The white balance is disabled.
1	The white balance is enabled.

				BIPART	RENABLE	GENABLE	BENABLE	ENABLE
Access				R/W	R/W	R/W	R/W	R/W
Reset				0	0	0	0	0

Bit 4 – BIPART Bipartite Table Configuration

Value	Description
0	Bipartite table is disabled. There are 64 points of interpolation from 0 to 4095.
1	Bipartite table is enabled. There are 32 points of interpolation (spacing is 8) from 0 to 255, then there are 30 points of interpolation from 256 to 4095.

Bit 3 – RENABLE Gamma Correction Enable for R Channel

Value	Description
0	12-bit to 10-bit compression is performed skipping two bits.
1	Piecewise interpolation is used to perform 12-bit to 10-bit compression for the red channel.

Bit 2 – GENABLE Gamma Correction Enable for G Channel

Value	Description
0	12-bit to 10-bit compression is performed skipping two bits.
1	Piecewise interpolation is used to perform 12-bit to 10-bit compression for the green channel.

Bit 1 – BENABLE Gamma Correction Enable for B Channel

Value	Description
0	12-bit to 10-bit compression is performed skipping two bits.
1	Piecewise interpolation is used to perform 12-bit to 10-bit compression for the blue channel.

Bit 0 – ENABLE Gamma Correction Enable

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Description
0	Gamma correction is disabled.
1	Gamma correction is enabled.

© 2026 Microchip Technology Inc. and its subsidiaries

Bit	7	6	5	4	3	2	1	0
				TAP2			FILTCFG[1:0]	
Access				R/W			R/W	R/W
Reset				0			0	0

Bits 31:28 – FLMAX[3:0] Flush Latency Maximum
Defines the maximum number of valid cycles between two lines when the pipeline generates lines.

Bits 27:24 – FLMIN[3:0] Flush Latency Minimum
Defines the minimum number of valid cycles between two lines.

Bits 11:8 – OFFSET[3:0] Resampling Default Phase
Defines the phase initialization of the filter.

Bit 4 – TAP2 Bilinear Interpolation

Value	Description
0	Custom tap values are used (see ISC_VXS_TAP10PHI).
1	Bilinear interpolation is used.

Bits 1:0 – FILTCFG[1:0] Vertical Filter Initial Configuration
Defines how the resampling filter will be initialized. Use value 1 for RGB interpolated pixel stream.

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.46. ISC HXS Configuration Register

Name: ISC_HXS_CFG
Offset: 0x3B0
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGEN is cleared in ISC_WPMR.

52.7.58. ISC Control Register

Name: ISC_CBHS_CTRL
Offset: 0x4D0
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCREN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								ENABLE
Access								R/W
Reset								0

Bit 0 – ENABLE Contrast, Brightness, Hue and Saturation Control Enable

Value	Description
0	CBHS control is disabled.
1	CBHS control is enabled.

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.59. ISC CBHS Configuration Register

Name: ISC_CBHS_CFG
Offset: 0x4D4
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGEN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access

Bit	7	6	5	4	3	2	1	0
						CCIRMODE[1:0]		CCIR
Access						R/W	R/W	R/W
Reset						0	0	0

Bits 2:1 – CCIRMODE[1:0] CCIR656 Byte Ordering

Value	Name	Description
0	CBY	Byte ordering Cb0, Y0, Cr0, Y1
1	CRY	Byte ordering Cr0, Y0, Cb0, Y1
2	YCB	Byte ordering Y0, Cb0, Y1, Cr0
3	YCR	Byte ordering Y0, Cr0, Y1, Cb0

Bit 0 – CCIR CCIR656 Stream Enable

Value	Description
0	Raw mode.
1	CCIR656 stream.

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.60. ISC CBHS Brightness Register

Name: ISC_CBHS_BRIGHT
Offset: 0x4D8
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGEN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
						BRIGHT[10:8]		
Access						R/W	R/W	R/W
Reset						0	0	0

Bit	7	6	5	4	3	2	1	0
	BRIGHT[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 10:0 – BRIGHT[10:0] Image Brightness Control (signed 11 bits 1:10:0)
Brightness value is added or subtracted from the luminance Y data.

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.61. ISC CBHS Contrast Register

Name: ISC_CBHS_CONT
Offset: 0x4DC
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGEN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
					CONTRAST[11:8]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
	CONTRAST[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 11:0 – CONTRAST[11:0] Contrast (unsigned 12 bits 0:4:8)
Adjusts the image contrast by multiplying with YCbCr data.

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.62. ISC Hue Register

Name: ISC_CBHS_HUE
Offset: 0x4E0
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGEN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								R/W
Reset								0

Bit	7	6	5	4	3	2	1	0
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 8:0 – HUE[8:0] Image Hue Value (unsigned 9 bits 0:9:0)
Programs the hue with angle in degree the range is [0:359] The hue control is implemented by mixing Cb and Cr data.

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.63. ISC CBHS Saturation Register

Name: ISC_CBHS_SAT
Offset: 0x4E4
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGEN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
					SATURATION[11:8]			
Access					R/W	R/W	R/W	R/W
Reset					0	0	0	0

Bit	7	6	5	4	3	2	1	0
	SATURATION[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 11:0 – SATURATION[11:0] Image Saturation Value (unsigned 12 bits 0:8:4)
Saturation is adjusted by multiplying both Cb and Cr by a constant.

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.64. ISC Subsampling 4:4:4 to 4:2:2 Control Register

Name: ISC_SUB422_CTRL
Offset: 0x4E8
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCREN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
								ENABLE
Access								R/W
Reset								0

Bit 0 – ENABLE 4:4:4 to 4:2:2 Chrominance Horizontal Subsampling Filter Enable

Value	Description
0	Subsampler is disabled.
1	Subsampler is enabled.

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.65. ISC Subsampling 4:4:4 to 4:2:2 Configuration Register

Name: ISC_SUB422_CFG
Offset: 0x4EC
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGEN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			FILTER[1:0]			CCIRMODE[1:0]		CCIR
Access			R/W	R/W		R/W	R/W	R/W
Reset			0	0		0	0	0

Bits 5:4 – FILTER[1:0] Low Pass Filter Selection

Value	Name	Description
0	FILT0CO	Cosited, {1}
1	FILT1CE	Centered {1, 1}
2	FILT2CO	Cosited {1,2,1}
3	FILT3CE	Centered {1, 3, 3, 1}

Bits 2:1 – CCIRMODE[1:0] CCIR656 Byte Ordering

Value	Name	Description
0	CBY	Byte ordering Cb0, Y0, Cr0, Y1
1	CRY	Byte ordering Cr0, Y0, Cb0, Y1
2	YCB	Byte ordering Y0, Cb0, Y1, Cr0
3	YCR	Byte ordering Y0, Cr0, Y1, Cb0

Bit 0 – CCIR CCIR656 Input Stream

Value	Description
0	Raw mode.
1	CCIR mode.

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.66. ISC Subsampling 4:2:2 to 4:2:0 Control Register

Name: ISC_SUB420_CTRL
Offset: 0x4F0
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCREN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
Access								
Reset								

Bit	7	6	5	4	3	2	1	0
			MIPI420	FILTER				ENABLE
Access			R/W	R/W				R/W
Reset			0	0				0

Bit 5 – MIPI420 MIPI YUV 420 8-bpp or 10-bpp Even Odd Splitter

Value	Description
0	Normal mode.
1	When the MIPI interface is selected and the source format is YUV 420 RMS (recommended memory storage), the sub420 submodule routes data lanes depending on the parity of the line received (odd or even).

Bit 4 – FILTER Interlaced or Progressive Chrominance Filter

Value	Description
0	Progressive filter {0.5, 0.5}.
1	Field-dependent filter, top field filter is {0.75, 0.25}, bottom field filter is {0.25, 0.75}.

Bit 0 – ENABLE 4:2:2 to 4:2:0 Vertical Subsampling Filter Enable (Center Aligned)

Value	Description
0	Subsampler disabled.
1	Subsampler enabled.

© 2026 Microchip Technology Inc. and its subsidiaries

52.7.67. ISC Rounding, Limiting and Packing Configuration Register

Name: ISC_RLP_CFG
Offset: 0x4F4
Reset: 0x00000000
Property: Read/Write

This register can only be written if WPCFGEN is cleared in ISC_WPMR.

Bit	31	30	29	28	27	26	25	24
Access								
Reset								

Bit	23	22	21	20	19	18	17	16
Access								
Reset								

Bit	15	14	13	12	11	10	9	8
	ALPHA[7:0]							
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	YMODE[1:0]		LSH	REP	MODE[3:0]			
Access	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Bits 15:8 – ALPHA[7:0] Alpha Value for Alpha-enabled RGB Mode
This field is relevant for ARGB444, ARGB555 and ARGB32 pixel formats.

Bits 7:6 – YMODE[1:0] YCbCr Memory Mapping Configuration Mode
YMODE is only available for YCYC and YCYC_Limited modes.

Value	Name	Description
0	RLP_YCBYCR	Byte 0 is Cr, Byte 1 is Y(n), Byte 2 is Cb, Byte 3 is Y(n+1)
1	RLP_YCRYCB	Byte 0 is Cb, Byte 1 is Y(n), Byte 2 is Cb, Byte 3 is Y(n+1)
2	RLP_CBYCRY	Byte 0 is Y(n), Byte 1 is Cr, Byte 2 is Y(n+1), Byte 3 is Cb
3	RLP_CRYCBY	Byte 0 is Y (n), Byte 1 is Cb, Byte 2 is Y(n+1), Byte 3 is Cr

Bit 5 – LSH Logical Left Shift for Pixel to 16-bit Container Mapping

Value	Description
0	Logical left shift is disabled.
1	Pixel value is left-justified in a 16-bit container.

Bit 4 – REP Pixel Expansion with Replication Logic

Value	Description
0	Replication is disabled.
1	Replication is enabled.

Bits 3:0 – MODE[3:0] Rounding, Limiting and Packing Mode

© 2026 Microchip Technology Inc. and its subsidiaries

Value	Name	Description
0	DAT8	8-bit data
1	DAT9	9-bit data
2	DAT10	10-bit data
3	DAT11	11-bit data
4	DAT12	12-bit data
5	DATY8	8-bit luminance only
6	DATY10	10-bit luminance only
7	ARGB444	12-bit RGB+4-bit Alpha (MSB)
8	ARGB555	15-bit RGB+1-bit Alpha (MSB)
9	RGB565	16-bit RGB
10	ARGB32	24-bits RGB mode+8-bit Alpha
11	YYCC	YCbCr mode (full range, [0–255])
12	YYCC_LIMITED	YCbCr mode (limited range)
13	YCYC	Y(n+1)CbY(n)Cr 422 interleaved full range per component 8-bit [0–255]
14	YCYC_LIMITED	Y(n+1)CbY(n)Cr 422 interleaved limited range per component 8-bit
15	BYPASS	32-bit input is sampled and written to the rlp output port. Select this mode for MIPI RMS mode.
